Oat variety tests in Montana, A. M. SCHLEHUBER, J. J. STURM, and R. H. BAMBERG. (Coop. U. S. D. A.). (*Montana Sta. Bul. 399 (1942), pp. 20, fig. 1*).—On irrigated land at Bozeman (1930-40) the midseason oats varieties, as Victory and Bridger, outyielded the early varieties, while on dry land at Havre and Moccasin (1930-40) and Huntley (1928-33) the earlier varieties, as Gopher, Markton, and Markton × Victory, were superior. Victory had the highest test weight per bushel of varieties at Bozeman. At Havre two Markton × Victory selections were heavier than Gopher, which averaged heavier than Markton, Colorado 87, Swedish Select, and Banner. At Moccasin there were only slight

differences between varieties. The average percentage of protein of nine varieties tested at Bozeman ranged from 14.65 for Gopher to 11.40 for Markton × Victory, whereas differences in percentage of hulls were not significant. Lodging was important only under irrigation at Bozeman. Gopher (0.72), Markton × Victory (C. I. 3976) (9.0), and Bridger (9.6 percent) lodged appreciably less than Victory (20.5 percent). Bridger and Victory are recommended for irrigated land and Gopher for dry or nonirrigated land.

Peanut production for oil in the national defense program, E. R. COLLINS. (N. C. Expt. Sta.). (*Amer. Fert.*, 96 (1942), No. 10, pp. 6-7).—Practical recommendations are made on selection of soils and varieties, cultural methods, fertilizer and liming practices for the older and newer peanut areas, and rotations.

Experiments with early potatoes on sandy loam in southern Ohio, J. BUSHNELL (*Ohio Sta. Bimo. Bul.* 215 (1942), pp. 63-70, fig. 1).—Variety, seed, cultural, fertilizer, and rotation and cover crop experiments, 1929-41, at the Washington County Truck Farm near Marietta are summarized, with comments on potato diseases and insects. Chenango sandy loam proved to be excellent for early potatoes, the 13-yr. average yield of marketable tubers being 256 bu. per acre. Warba, 343 bu. No. 1 per acre, averaged higher in yield than Irish Cobbler, 304 bu., and both outyielded other early varieties. Yields from certified Cobblers grown in various seed-producing districts did not differ much. Cobblers grown at Wooster from early-May or early-June plantings were suitable for seed, producing about the same as northern certified seed. While a 6-8-8 fertilizer at 1,000 lb. per acre was ample for yields of 300 bu. per acre, a somewhat heavier rate is suggested if a higher yield is anticipated. Early potatoes were grown for 8 successive years on the same land without difficulties. Winter barley sown in August proved very satisfactory as a cover crop.

Adventitious roots on panicles of rice, J. W. JONES and M. N. POPE. (U. S. D. A.). (*Jour. Hered.*, 33 (1942), No. 2, pp. 55-58, figs. 2).—The occurrence of adventitious roots on panicles of Nira and Caloro rice is described and illustrated, with remarks on behavior in inheritance.

Influence of variety, environment, and fertility level on the chemical composition of soybean seed, J. L. CARTER and T. H. HOPPER (*U. S. Dept. Agr. Tech. Bul.* 787 (1942), pp. 66, figs. 10).—In the 10 representative varieties studied the percentages of carbohydrate, nitrogenous, lipide, and mineral constituents in the soybean appeared to be influenced by the physiological vigor as controlled by the environment during the entire growth period of the plant. The iodine number of the oil from the seed of a variety appeared to be critically influenced by the prevailing temperatures during the period of bean development and oil metabolism. High temperatures depressed and low temperatures raised the iodine number. In general, the oil content of the soybean seed is most specifically a varietal characteristic, and the iodine number of the oil is about equally influenced by variety and climate under the observed conditions. As a rule, no large variations in the percentages of crude fiber in the seed and unsaponifiable matter in the oil were observed. Some variation in these constituents due to variation in seed size and ratio of seed coat to cotyledon was noted, however. High calcium content always resulted when the soybeans were grown at high temperatures. Total ash, phosphorus, and potassium content of the seed appeared to be influenced more by soil type and fertility than by variety or variations in climate. Fertility level affected yield but was without noticeable effect on composition of soybean seed with respect to oil and protein content and iodine number of the oil. Within the limits ordi-

narly encountered in breeding and variety testing, soil fertility did not appear to affect the relative rank or order of varieties and strains of soybeans with respect to these components. Varieties were found to differ significantly in composition. Pedological and climatic factors did not greatly influence the relative standing or ranking of the several varieties with reference to the percentages of oil, protein, phosphorus, and calcium. The importance of this work is in the finding that varieties and strains of soybeans seem to inherit their characteristic chemical composition, making possible progress in breeding for desired chemical composition as well as for yield and other agronomic factors. See also an earlier note (E. S. R., 86, p. 322).

Varieties of spring wheat for the North Central States, J. A. CLARK. (Coop. State expt. stas. et al.). (*U. S. Dept. Agr., Farmers' Bul. 1902 (1942), pp. 11+20, figs. 19*).—Varieties of hard red spring wheat, durum and red durum, and white spring wheat grown in the Northern Plains and Prairie States are described, with remarks on adaptations and market classes of spring wheats. The information given supersedes that in Farmers' Bulletins 1621 (E. S. R., 63, p. 635) and 1706 (E. S. R., 70, p. 614).

Oklahoma farm wheat improvement program: Summary report, 1937–1941, inclusive, H. S. SMITH (*Oklahoma Sta. Misc. Pub. 6 (1942), pp. [1]+24, figs. 2*).—Farmers' wheat samples (E. S. R., 85, p. 47) tested, 1939–41, averaged 8.5, 14.1, and 77.4 percent of A, B, and C grades, respectively, based upon the Canadian crop-testing method. Average milling and baking results of 54 samples of 4 important wheat varieties agreed with other reports. Chiefkan ranked below Tenmarq, Turkey, and Blackhull, being particularly undesirable in dough properties, loaf volume, and color. Of 7 hard winter wheat varieties grown at a number of locations, 1939–41, Chiefkan averaged 19.3 bu. per acre, Tenmarq 19.2, Early Blackhull 18.2, Cheyenne 17.5, Blackhull 16.9, Kanred 16.8, and Turkey 15.9 bu. Chiefkan and Early Blackhull grown in 1941 averaged highest in weight per bushel. Protein percentage determined for the 1941 crop was for Chiefkan 16.3, Kanred 15.7, Comanche 15.7, Tenmarq, 15.5, Blackhull 15.0, Cheyenne 14.9, and Turkey 14.5. Mixed wheat, foreign material (rye), and smut reports, 1937–41, revealed a marked reduction in the amount of mixed wheat marketed. Rye and smut were also becoming less important as grading factors at inspection points in the State.

Winter wheat production in Colorado, D. W. ROBERTSON, J. J. CURTIS, D. KOONCE, J. F. BRANDON, and O. H. COLEMAN. (Coop. U. S. D. A.). (*Colorado Sta. Bul. 470 (1942), pp. [23], figs. 2*).—Cultural methods and field practices, derived from experiments and experience, are outlined for growing winter wheat on dry land and under irrigation. Results of further (E. S. R., 70, p. 330) varietal trials, 1933–40, at Akron on dry land, under irrigation at Fort Collins (5,000 ft.), and Fort Lewis (7,610 ft.) recommended Kanred, Tenmarq, and Nebred as the best-adapted hard red winter wheats.

Rate and date of seeding winter wheat in eastern Colorado, D. W. ROBERTSON, J. F. BRANDON, H. FELLOWS, O. H. COLEMAN, and J. J. CURTIS. (Coop. U. S. D. A.). (*Colorado Sta. Bul. 472 (1942), pp. 9, figs. 4*).—The main conclusions from these experiments have been noted from another source (E. S. R., 87, p. 218).

Wheat production in California, C. A. SUNESON and F. N. BRIGGS. (Coop. U. S. D. A.). (*California Sta. Bul. 659 (1941), pp. 18, fig. 1*).—Yields, 1922–40, and other agronomic characters, results of milling and baking tests, and descriptions are given for wheat varieties under study. Methods of producing the crop, its diseases and insect pests and their control, and commercial uses are reviewed, and the backcrossing procedure used to improve California wheat is

described. Baart, White Federation, and Big Club currently comprise 60 percent of the total wheat acreage. Transfer, by backcrossing, of resistance to stem rust and to smut from nonadapted wheats to these three varieties probably will have enough practical value to increase their culture to 85 percent of the total California acreage within 5 yr. Certain of the poorer-yielding varieties, as Pacific Bluestem and Big Club, have advantages for hay or pasture that justify production in certain situations.

Protein and quality in hard red spring wheat with respect to temperature and rainfall, L. R. WALDRON, R. H. HARRIS, T. E. STOA, and L. D. SIBBITT (*North Dakota Sta. Bul. 311 (1942), pp. 20, fig. 1*).—When eight wheat varieties were grown in four localities in North Dakota, 1937–40, the mean protein content of the wheats varied decidedly from year to year but relatively little from one locality to another. The protein content of Thatcher, 15.1 percent, was 1.3 above Marquis, but it was not evident that this difference was due to stem rust. Errors of estimate of loaf volume calculated from the protein content showed high values for 1937 and 1938 and low values for the last 2 yr. Thus protein showed marked differences in efficiency in different years. High maximum and minimum temperatures for the 10-day preheading period have been associated with greater loaf volume, but only high maximum temperatures were found associated with high protein. A smaller degree of correlation was found between similar temperatures and loaf volume and protein for the first half of the post-heading period. For the second half of the post-heading period loaf volume was correlated negatively with maximum and minimum temperatures, and for the same period correlations between temperatures and protein content were near zero. No relationship was found between protein content and precipitation, which was not high during the period.

Proceedings of the Association of Official Seed Analysts, 1941 (*Assoc. Off. Seed Anal. Proc., 33 (1941), pp. 106, figs. 17*).—Papers presented at the thirty-third annual meeting at Ames, Iowa, July 8–11, 1941, included Germination of Green Foxtail Seeds, by A. C. Heise (pp. 43–44); Germination of Seeds of *Agropyron* sp. (Probably Quack Grass) and *Thlaspi arvense*, Penny Cress, by R. B. Schulte and P. Balbach (pp. 44–45); Viability of Injured Seeds of *Avena fatua* L., by E. R. Clark (pp. 46–47), The Pretreatment of Buffalo Grass for Field Planting—A Preliminary Report, By A. F. Musil (pp. 76–82), and Germination of Freshly Harvested Seed of Kentucky Bluegrass (pp. 96–98) and The Effect of Different Temperatures on the Germination of Freshly Harvested and Mature Seed of *Axonopus compressus* (pp. 99–102), both by A. M. Anderson (all U. S. D. A.); Viability of Injured Weed Seed, *Bromus tectorum*, by L. A. Kanipa (pp. 48–50) (Oreg. Expt. Sta.); The New Iowa Seed Law, by H. D. Linn (pp. 58–60); Test for Homogeneity in Seed Germination Tests, by R. G. Cochran (pp. 60–63), with discussions by C. W. Leggatt and R. H. Porter; Evaluation of Media for Seed Germination, by V. J. Thompson (pp. 63–64), Viability and Germination of Seeds of Field Bindweed, *Convolvulus arvensis* L., and Other Noxious Weeds, by E. O. Brown and R. H. Porter (pp. 64–65), and Effect of Low Temperatures on the Germination of Sorghum and Soybean Seeds, by W. A. Robbins (pp. 95–96) (all Iowa State Col.); and Split Seeds in Peas and Beans, by W. Crosier (pp. 66–69), Some Observations in the Germination of Grass Seeds, by W. Crosier and B. Cullinan (pp. 69–74), Germinating Seeds of Southern Grasses, by B. Cullinan (pp. 74–76), The Production of Clover Seed, by L. E. Iverson (pp. 82–84), Laboratory Germination of Belladonna (*Atropa belladonna*) Seed, by C. E. Helt (pp. 84–87), Approximate Germination Tests of Dormant Seeds by Excising Embryos, by C. E. Helt and C. Nelson (pp. 87–89), New Zealand

Spinach Germination Studies, by C. E. Helt and M. T. Munn (pp. 90-95), and Some Seed Control Field Problems, by M. T. Munn and B. E. Clark (pp. 103-104) (all N. Y. State Sta.).

Technical problems were also dealt with in committee reports.

HORTICULTURE

[Horticultural studies by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 414 (1941), pp. 19-21, 30-34, 49-53, 54, figs. 3).—Included are reports of studies on the culture and fertilization of roses, by E. I. Wilde and R. P. Meahl; the breeding of snapdragons, by M. T. Lewis; the testing of aster species and varieties, by Wilde; the use of growth-promoting chemicals on the cuttings of ornamentals, by Meahl; soil management of apple, peach, and cherry orchards, by R. D. Anthony, C. O. Dunbar, W. S. Clarke, Jr., and N. Shaulis; the K requirements of peach trees, by Anthony, E. C. Dunkle, and F. G. Merkle; rootstocks for apples and cherries, by Clarke and Anthony; the use of growth-promoting substances for apple and cherry cuttings, by H. K. Fleming; the relation of cold spots in orchards to losses of fruit crops, by Clarke; the breeding of rhubarb, tomatoes, and lettuce, by C. E. Myers and Lewis; the testing of vegetable varieties, by E. M. Rahn; the testing of hybrid sweet corn, by Myers; the use of starter solutions for tomatoes, by Rahn; fertilizer placement with tomatoes; the relation of irrigation to economy of fertilizing vegetables, by G. J. Stout; and composts for mushrooms, by J. W. Sinden.

Fruits and vegetables (*South Dakota Sta. Rpt.* 1941, pp. 49-50, 51-54).—Among studies, the progress of which is reported by N. E. Hansen, W. F. Buchholtz, L. L. Davis, and S. A. McCrory, are the testing of new ornamentals, breeding of fruits, breeding of roses, development of apricots with sweet kernels, the Siberian apricot as an ornamental, polyploidy in the apple, development of new varieties of tomatoes, growth of various trees and shrubs in the shelterbelt as influenced by fertilizer and culture, and the breeding of hybrid sweet corn.

[Horticultural studies by the Wisconsin Station] (*Wisconsin Sta. Bul.* 455 (1942), pp. 57-62, 64, 66, 73-74).—Information is given on the progress of studies by J. C. Walker, J. P. Jolivet, W. W. Hare, K. Berger, E. Truog, E. J. Delwiche, L. Muskavitch, O. B. Combs, W. B. Ennis, R. H. Andrew, and N. P. Neal dealing with the effect of borax on canning peas, the fertilization of canning peas, canning pea varieties, tomato varieties, the spraying of tomatoes, the value of hybrid varieties of sweet corn, fertilizers for sweet corn, the application of borax to beets, fertilizers for beets, the use of copper and boron for celery grown on peat soil, and the resistance of red raspberries to low-temperature injury.

A rapid method of determining when a plant is killed by extremes of temperatures, G. A. FILINGER and A. B. CARDWELL. (Kans. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 85-86, fig. 1).—Resistance measurements made with a standard bridge were found useful in determining when plant tissues had been killed. Red raspberry canes killed by freezing or boiling lost from 72 to 82 percent of their resistance.

The effects of fertilizers, organic material, and irrigation on the yield of certain truck crops, L. M. WARE. (Ala. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 363-366).—Three years' results are presented on the yield of certain truck crops grown in concrete bins of uniformly prepared soil treated differentially with respect to organic matter and water. Commercial fertilizers were applied in like amounts to all plats. In the first year with adequate rain throughout the growing season and no build-up of organic matter in

the soil, no benefit resulted from the use of either organic matter or irrigation for either of the spring crops potatoes and beans. After the first year, while irrigation and organic matter used singly gave slight to large increases in yield, the maximum increases were attained only when the two were used in combination. Attempts to grow organic matter on the plats rather than to introduce it from outside sources were successful. Fall seedings of vetch gave very promising results, and cowpeas also showed promise for preceding fall-grown crops.

Limits in the use of borax in the production of certain vegetable crops, R. H. WHITE-STEVENS. (Cornell Univ.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), p. 367).—Among vegetable crops grown on Long Island, cauliflower, rutabagas, table beets, mangolds, and radishes showed particular need for boron. In some cases boron increased the yields of potatoes and peas, particularly when grown on soils which had produced cauliflowers showing boron deficiency symptoms. With peas and potatoes 5 lb. of borax were adequate, and greater amounts tended to reduce yields particularly if repeated for several years. Snap beans, lima beans, spinach, and carrots did not give increased yields with 5 lb. of boron per acre, and larger amounts decreased yields. Sweet corn did not respond to borax up to 20 lb. per acre. In wet seasons higher rates of borax are needed than in dry years. The inclusion of small amounts of borax in bordeaux mixture or in water was found to be an effective means for supplemental applications.

Storage of vegetable seeds, E. H. TOOLE (*U. S. Dept. Agr. Leaflet* 220 (1942), pp. 8, figs. 2).—Information is given on the importance of conserving seed supplies, general principles of seed storage, moisture changes in seeds, maintenance of seed viability, cold storage as a means of preserving viability, methods of drying seeds, etc.

[Vegetable studies by the Illinois Station] (*Illinois Sta. Rpt.* 1938, pp. 281-296).—Among studies by J. W. Lloyd, J. P. McCollum, W. A. Huelsen, and K. J. Kadow, the progress of which is noted, are the effect of time of plowing under cover crops, the effect of the severity of cutting on asparagus yields, methods of fertilizing asparagus, breeding of disease-resistant cabbage and high-quality onions, breeding of sweet corn, effect of stand of plants on sweet corn yields, tomato breeding, fertilization of greenhouse tomatoes, adaptation of new varieties of lima beans for freezing preservation, tomato spraying, culture of the horseradish, and tomato cultural practices.

Yield of sweet corn in relation to distance and rate of planting, W. A. HUELSEN (*Illinois Sta. Bul.* 487 (1942), pp. 33-104, figs. 32; abs., pp. [4]).—Preliminary experiments with 50 different checked-row and 40 different drilled-row plantings of Country Gentleman and Narrow Grain Evergreen sweet corn indicated that changing the distance between rows, the number of plants to the hill, and the spacing between plants in the rows had a highly complex and varying effect on yields. Further studies with 16 different checked-row and 12 different drilled-row plantings replicated four times made possible an analysis of the differential effects on several of the yield components of both varieties. The nature of the yield variations was such as to suggest that while space occupied per plant may have strongly influenced yields, other factors exercised a partially independent effect. The weight of usable unhusked and prime husked ears tended to respond in the same manner as weight of green fodder and height of plants, but the relationship was not very close. In general, planting distances and rates that were favorable for maximum production of one yield component were not necessarily favorable for others. Varieties responded differently to changing rates and distances of planting. However, in drilled rows, plantings of Narrow Grain Evergreen and Country Gentleman reacted practically the same, with the correct

distances between rows being more important than correct distance between plants in the row. In dry years a decrease in distance between hills reduced the height of plants, but increasing the number of plants in the hill had only a slight effect on plant height. Maturity was delayed much more by an increase in rate per hill or by closer planting in the row than it was by reducing the distance between rows.

Cucumber growing, W. R. BEATTIE (*U. S. Dept. Agr., Farmers' Bul. 1563, rev. (1942), pp. 11+25, figs. 15*).—Replacing an earlier publication (E. S. R., 59, p. 742), this contains general information as to soils, culture, pollination requirements, harvesting, marketing, control of pests, etc.

Growing garlic in the North, D. COMIN (*Ohio Sta. Bimo. Bul. 215 (1942), pp. 70-71*).—Spring plantings of garlic failed to give either large-sized bulbs or sufficient yields. Where local strains of garlic were planted in October much better production was obtained, and over a 4-yr. period the local stocks proved to be winter hardy.

The effect of storage on the carbohydrates of the Ebenezer onion, E. BENNETT. (Mass. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 39 (1941), pp. 293-294*).—Analyses of onions, grown under known conditions and stored in (1) high temperature and low relative humidity, (2) low temperature and high relative humidity, and (3) conditions intermediate between lots 1 and 2, showed the greatest loss, 8.12 percent, of total sugars in the period November 1 to February 15 in the onions of lot 1. The losses were not large, even under the most adverse conditions. The largest percentage of marketable onions was obtained from the storage having the lowest mean temperature and the highest mean relative humidity. Decayed onions were negligible in all three environments. Sprouting was minimized by holding the temperature at about 32° F.

The vernalization of tomato seed, D. W. GOODALL and B. D. BOLAS (*Ann. Appl. Biol., 29 (1942), No. 1, pp. 1-10*).—Tomato seeds of the Potentate variety were chilled in a moist state, but before germination, at temperatures of 0°, 2°-3°, 7°, and 8°-11° C. for periods of 10 to 20 days. Later they were germinated, together with control seeds, under conditions of both restricted and fully adequate moisture. The plants grown from chilled seeds produced the more fruit, particularly during the first few weeks of cropping. Their first two leaves were opposite in a greater proportion of instances, the effect being more marked after treatment at the higher temperatures. Both leaf area at a given date and fruit size during the first weeks of cropping were greater in the series germinated with a full moisture supply than in those with restricted moisture. The dates of first flowering and fruiting were not affected by the treatments.

The interactions between variety, spacing, and staking of tomato plants, T. M. CURRENCE. (Minn. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 39 (1941), pp. 315-318*).—Maximum early production was obtained from close spacing, 1 ft. between plants giving the highest yields for the first five pickings. Varieties responded differently to pruning; for example, Break o' Day (of standard growth habits) benefited from pruning, while Pritchard (of determinate growth habits) was harmed. The total yields of all varieties were uniformly reduced by pruning. Yields of plants staked without pruning were approximately equal to those of untreated plants. Yields of the Dwarf Champion variety were reduced drastically by a combination of pruning and staking. Fruit size was increased by staking, and particularly by staking plus pruning.

Effect of indolebutyric acid upon tomato fruit set and development, F. S. HOWLETT. (Ohio Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc., 39 (1941), pp. 217-227, figs. 4*).—Indolebutyric acid proved to be very effective, both in number and size of fruits produced and in the extensive development of gelatinous pulp

within the locules. Equally good results were obtained when the chemical was used to supplement pollen of low viability. The chemical used in the form of lanolin emulsion was frequently superior to the paste form, except that it caused considerable blossom-end rot.

[Pomological studies by the Illinois Station] (*Illinois Sta. Rpt. 1938, pp. 263-266, 267-270, 271-279, 280-281, fig. 1*).—Progress reports by J. C. Blair, M. J. Dorsey, J. S. Whitmire, W. A. Ruth, R. L. McMunn, W. P. Flint, A. S. Colby, and H. W. Anderson are presented on the following studies: Apple breeding; apple tree training; fertilization of apple trees; comparative resistance of apple varieties to low temperature; removal of spray residues from apples; effect of different soil management practices on soil moisture availability for apple trees; the testing of Chinese peach seedlings; peach breeding; lespedeza as a cover crop for peach orchards; peach fruit thinning; effect of low winter temperatures on peaches, cherries, and plums; the value of the mahaleb cherry as an understock; grape cluster thinning; the testing of nut and small fruit varieties; the breeding of strawberries for resistance to red stele disease; and the breeding of gooseberries and black raspberries.

Fruit varieties for Ohio: Descriptions of recommended and new varieties, with planting directions, C. W. ELLENWOOD, L. HAVIS, and F. S. HOWLETT (*Ohio Sta. Bul. 627 (1942), pp. [1]+50, figs. 8*).—Accompanied by brief directions as to the selection of orchard sites and planting plans and methods, data are presented on varieties of tree and small fruits for commercial, roadside market, and home uses. In tabular form data are presented on the color of flesh, size of fruit, quality, approximate ripening dates, and principal uses of a large number of peach varieties grown at Wooster.

The home fruit garden in the East Central and Middle Atlantic States (*U. S. Dept. Agr. Leaflet 218 (1942), pp. 8, figs. 2*).—This leaflet lists the best kinds and varieties of fruits and nuts for home planting in the middle region of the eastern United States, and gives brief directions for their planting and care.

The home fruit garden in the southeastern and central Southern States (*U. S. Dept. Agr. Leaflet 219 (1942), pp. 8, figs. 2*).—This leaflet lists the best kinds and varieties of fruits and nuts for home planting in the southeastern United States and gives brief directions for their planting and care. The region is divided into climatic districts.

Establishing and managing young apple orchards, J. R. MAGNESS (*U. S. Dept. Agr., Farmers' Bul. 1897 (1942), pp. 11+29, figs. 16*).—This paper discusses the need for planting orchards, the selection of desirable locations, the planning and planting of the orchard, soil management, pruning, spraying, etc.

Some correlations between growth and yield of the apple in central Washington, E. L. OVERHOLSER, F. L. OVERLEY, and J. C. WILCOX. (*Wash. Expt. Sta.*). (*Amer. Soc. Hort. Sci. Proc., 39 (1941), pp. 11-15*).—A study of growth and yield records available on Jonathan, Rome Beauty, and Winesap trees showed highly significant positive correlations between cross-sectional area of trunk and increase in trunk circumference and between cross-sectional area of trunk and growth index in Jonathan and Rome Beauty. In general, the larger trees tended to be more vigorous than smaller trees. Correlations between terminal length and weight of fruit, between increase in trunk circumference and weight of fruit, and between growth index and weight of fruit were all highly significant in the case of Jonathan. The same tendencies were noted in Winesap, but were not as pronounced in Rome Beauty. Apparently increase in trunk circumference and growth index was preferable to terminal length as a measure of tree growth over a period of years.

In a group of Jonathan trees, in which very little tendency toward systematic biennial bearing was noted over a period of years, a distinct tendency was noted for a comparatively heavy crop to be followed by a comparatively light crop, and vice versa. The sequence lasted rarely for more than 2 or 3 yr. at any one time. Terminal growth tended to be longer in the "on" year than in the "off" year. The increase in trunk circumference tended to be smaller in the on than in the off year.

Influence of sulphur sprays on the trunk diameter of young apple trees, E. P. CHRISTOPHER. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 8-10).—Measurements taken on trunk diameter increments of McIntosh and Baldwin trees following 2 yr. of various spray and dust treatments showed significant effects in only a few instances. McIntosh and Baldwin trees dusted with sulfur were significantly larger than those treated with liquid lime-sulfur 1 : 50. Baldwin trees sprayed with liquid lime-sulfur 1 : 100 were larger than those sprayed with liquid lime-sulfur 1 : 50.

The Idared apple, L. VERNER (*Idaho Sta. Cir.* 84 (1942), pp. 3).—The new variety, resulting from a cross of Wagener and Jonathan, is described as to tree and fruit characters. The fruit is bright red in color and has a very small core, creamy-white flesh, and superior keeping qualities.

Effect of ringing upon fruit set in some light-setting apple varieties, F. S. HOWLETT (*Ohio Sta. Bimo. Bul.* 216 (1942), pp. 107-112).—Experiments extending over a period of years led to the conclusion that, although ringing did increase fruit set significantly in some instances, its general use was not justified under Ohio conditions for increasing the fruit set of light-setting varieties. In some cases one pair of branches on a tree gave a favorable response to ringing, while another pair showed no response. Apparently, different chemical compositions may exist among the branches of a single tree. Under certain conditions ringing might be profitably used on such varieties as Paragon, Arkansas, and Nero. Ringing wounds should be carefully protected to promote healing. The time of ringing should be from the late-pink to the full-bloom stage. The fact that certain of the light-setting varieties are triploids and possess considerable egg cell sterility suggests the need of providing for effective cross-pollination and for keeping the trees in vigorous condition rather than using ringing as a means of increasing fruit set.

Regulating apple production with sprays to remove flowers, F. S. HOWLETT. (*Ohio Expt. Sta.*). (*Ohio State Hort. Soc. Proc.*, 75 (1942), pp. 91-100).—Various materials were tested as sprays which would reduce the set of apples sufficiently in the bearing year to permit flower buds to form for the succeeding light-crop year. Apple varieties were found to differ considerably in their response to a given treatment; for example, Elgetol at 0.6-percent concentration removed the flowers and fruit of Cortland and Melba but had little effect on Anoka, Ralls, and Baldwin. The flowers in the "on year" were apparently unusually vigorous and when cross-pollinated were capable of setting despite pronounced injury to the adjacent leaves. Annual bearers had a considerable proportion of weak flowers, many of which were easily prevented from setting. The timing of the sprays and the different materials are discussed, with a warning that the entire problem is still definitely in the experimental stage.

Preharvest sprays in 1940 and 1941, C. W. ELLENWOOD and F. S. HOWLETT (*Ohio Sta. Bimo. Bul.* 216 (1942), pp. 100-106).—In 1940, five commercial materials and home-made naphthaleneacetic acid solution were compared on several varieties of apples. There was no significant difference between the various materials on any one variety. On Jonathan and Stayman Winesap the sprays

caused a highly significant reduction in drop. On Baldwin, the results were not significant. The timing of sprays was highly important. For example, with Stayman Winesap an application on October 11 was not effective while that on October 16 reduced dropping by 15.8 percent compared with check trees. The condition of the foliage is believed highly important and possibly an explanation of the Baldwin results. In 1941, favorable responses were obtained with Duchess, Red June, Williams, Gravenstein, Melba, Wealthy, and Stayman Winesap. Again there was no appreciable difference between the materials used. In general a single application made 2 or 4 days preceding the normal date of beginning the harvest was as effective as two applications.

Sun-coloring experiments in 1941: Sun-coloring compared with use of harvest sprays as means of improving color, C. W. ELLENWOOD and T. E. FOWLER (*Ohio Sta. Bimo. Bul. 215 (1942), pp. 73-75*).—In 1941 a comparison was made of sun coloring McIntosh apples for 9 days with applications of preharvest sprays which caused the fruit to remain on the trees throughout the same period. Sun coloring gave better color and, although the apples softened appreciably, this did not interfere with their marketability. After 3 mo. of storage, both lots of fruit were approximately alike in firmness. Favorable results were obtained also from sun coloring Red Gravenstein apples. The response from sun coloring Gravenstein apples was much less marked than with the Red Gravenstein.

Irrigation experiments with pears and apples, A. H. HENDRICKSON and F. J. VEIHMEYER (*California Sta. Bul. 667 (1942), pp. 43, figs. 16*).—Studies on widely distributed plats of trees, some of which were kept continuously supplied with readily available moisture and some allowed to deplete the soil moisture to the permanent wilting percentage during certain periods, indicated that in the central-coast region in years of normal rainfall pear and apple trees on medium- or fine-textured soils do not exhaust the readily available moisture until late in the season. Mature pear orchards in districts where the climatic conditions resemble those of the interior valley, such as Lake, Mendocino, and Contra Costa Counties, exhaust the soil moisture to the permanent wilting percentage in the top 4 to 6 ft. about the last week in June or the first week in July and require one or two irrigations prior to harvest. When the readily available soil moisture is exhausted, the pear fruits slow down in growth on both medium- and fine-textured soil. However, if the permanent wilting percentage is not reached while the fruit is on the tree, its growth is not retarded.

In the apple studies conducted under mild climatic conditions, fruits slowed down in growth when the readily available moisture before the first foot was exhausted. If the permanent wilting percentage was not reached, the growth of fruit was not retarded.

As indicated by the pressure test, the maturity of pears was delayed if the readily available soil moisture was exhausted a week or more before the normal harvest period. Differences in maturity between fruit from the irrigated and nonirrigated plants tended to disappear in storage. Pears grew normally under a wide range of soil and climatic conditions, but harmful results such as decreased size and delayed maturity followed when the soil moisture was reduced to about the permanent wilting percentage during the growing season.

Relation of ripening temperature to market quality of Bartlett pears, C. O. BRATLEY and F. W. WILLEN. (U. S. D. A. and Univ. Calif.). (*Ice and Refrig., 102 (1942), No. 6, pp. 355-356, fig. 1*).—Observations on comparable lots of pears, one held in the cold storage plant at Davis, Calif., and the other shipped to New York City, indicated that pears which had been held at low temperatures ripened most effectively at moderate temperatures, 65°-70° F. Pears ripened at

83° or above softened more slowly than those held at 65°-70°. Some of the pears held at 83° failed to soften well and remained slightly firm until decay or break-down set in. Fruit which attained an edible condition kept essentially the same when placed at room temperature whether ripened at 65°-70° or at 83°.

Cultural factors affecting sour cherry production in Colorado. L. R. BRYANT and R. GARDNER (*Colorado Sta. Bul.* 471 (1942), pp. 19, figs. 3).—Interspersed with general information on the planning, cultural care, and pruning of Montmorency cherry orchards is information on the results of certain experiments. Attempts to develop organic matter in the cherry orchard by growing cover crops were impeded by shortage of moisture for both the tree and the cover crop. Moisture determinations on samples of soil collected periodically showed very little moisture available in excess of that needed by the trees and that before the end of the season in nearly every year the entire available supply was exhausted by the trees. Experiments showed that nitrogen applied either as commercial nitrogen or as stable manure increased yields significantly. The size of cherries was not influenced by fertilizer treatments but was increased by irrigation shortly before maturity of the fruit. Pruning decreased yields in order of severity, but a certain amount of light pruning is deemed essential.

Split-pit of peaches: Estimation of time when splitting occurs. L. D. DAVIS. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 183-189, figs. 5).—A method is described for estimating the time when pit splitting occurs by comparing the seasonal curves of the suture diameter : cross diameter ratio of the split and unsplit fruits calculated from the average size of the two diameters. The time when the curves rapidly diverge indicates when splitting begins. Fruits destined to have split pits are larger in both suture and cross diameters than nonsplitting fruits, and the ratio of the two diameters is smaller prior to pit hardening. The incidence of splitting may vary in different varieties in reference to the time pit hardening begins, and a single variety may show differences in time of splitting. Splitting occurred in all the cases studied after the pit began to harden. The differences in the seasonal changes of the suture diameter : cross diameter ratio in split and unsplit fruits are discussed.

Climate in relation to deciduous fruit production in California.—I, Effect of the warm winter of 1940-41 on peach and nectarine varieties in northern California, R. M. BROOKS and G. L. PHILP. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 190-194).—The results of a study of the effect of a mild winter on the fruiting performance of 280 peach and 58 nectarine varieties are presented, and the varieties are grouped in four classes: (1) No bud drop, (2) slight drop, (3) moderate drop, and (4) heavy drop. Most of the commercial varieties fell into classes 2 and 3. The varieties which showed little or no drop were mainly of the Honey or Peento groups.

An evaluation of peach and nectarine varieties in terms of winter chilling requirements and breeding possibilities. W. E. LAMMEETS. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 205-211, fig. 1).—A total of 50 varieties of peaches and nectarines were evaluated in terms of their winter chilling requirements, using the relatively constant reaction of Lukens as a standard for comparison. Some progress was made in the breeding of new varieties with a low chilling requirement by crossing high-quality commercial varieties with others having a low chilling requirement.

Blackberry growing. G. M. DARBOW (*U. S. Dept. Agr., Farmers' Bul.* 1399, rev. (1942), pp. 11+18, figs. 14).—In this revised edition (E. S. R., 51, p. 748), directions are given for locating the plantations, selection of soils, culture, propagation, pollination, training and pruning, winter protection, control of insects and diseases, and varieties for specific locations and for specific purposes.

Raspberry growing in New York: Culture, disease, and insects, G. L. SLATE, R. F. SUIT, and F. G. MUNDINGER (*New York State Sta. Cir. 153, rev. (1942), pp. 62, figs. 16*).—In this revision, the original of which was noted (E. S. R., 72, p. 624), information is presented on culture, pruning, varieties, harvesting, marketing, diseases and their control, noninfectious troubles such as winter injury, and insects and their control.

Inheritance of some characteristics in strawberry varieties, E. B. MORROW and G. M. DABROW. (N. C. Expt. Sta. and U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 262-268).—Observations on a large number of seedlings produced at Beltsville, Md., and Raleigh, N. C., and grown to maturity at Willard, N. C., revealed some outstanding characteristics attributable to the parental stock. In the mild winter of 1938-39 many more selfed seedlings of Blakemore and Missionary flowered by the middle of February than all other selfed varieties or of any cross. The late-flowering performance of these early-blooming seedlings indicated that conditions that make for early flowering make also for further extensive fruit bud formation. Data taken in 1940 on the time of ripening showed Missionary selfed and N. C. 640 selfed to have many early-ripening seedlings. Among crosses, over one-half of N. C. 225 × Fairmore and of Blakemore × N. C. 640 were in the early-maturing group. The largest berries were produced by Blakemore × Dresden, Catskill × N. C. 866, Blakemore × Massey, Catskill × Massey, and Catskill × Blakemore. In selfed lines, seedlings of Eleanor Roosevelt, Fairfax, and Southland averaged large in size. Selfed lines of Fairmore, N. C. 866, Blakemore, Eleanor Roosevelt, and Fairfax had a large percentage of firm berries. Southland selfed was noticeably soft. In crosses, both Catskill and Dresden transmitted a high degree of softness. Promising parental combinations are listed.

Transpiration in strawberries as affected by root temperature, G. F. GRAY. (Okla. A. and M. Col.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 269-273, figs. 2).—In 1939, plants of several varieties were grown in water cultures maintained at 85° and 100° F. At 85° the plants functioned apparently normally, while at 100° wilting occurred during the heat of the day on one or more leaves of practically all the plants. Transpiration was not greatly different in the first 24 hr., but in the second 24 hr. it was much less at 100° than at 85°.

In 1940 with soil instead of water, all varieties functioned normally throughout a 3-day period at 100°, although the transpiration rate was higher at 100° than at 85°. Results of two 10-day trials showed that the plants transpired at a higher rate at higher soil temperatures but that atmospheric humidity had a more direct influence on transpiration than did air temperature. Observations on the roots in soil at 100° showed a majority of the small fibrous roots to have turned brown after 3 days, and what new growth appeared was practically devoid of root hairs. There was no injury at 85°.

Strawberries for the home garden, J. H. CLARK (*New Jersey Stas. Cir. 436 (1942), pp. [4]*).—Information is presented as to the desirability of early planting; value of vigorous, healthy plants; fertilizers; weed control; mulching; rotations; and varieties.

A caution on the use of arsenicals to clear cranberry bogs for replanting, C. A. DOEHLERT. (N. J. Expt. Stas.). (*Amer. Cranberry Growers' Assoc., Proc. Ann. Mtg.*, 72 (1942), pp. 11-15, 18-19, fig. 1).—On a Savannah bog near Pemberton, N. J., plowed in the spring of 1938 and rototilled during the summer to prepare for replanting, a half acre was sprayed at planting time in the spring of 1939 with an arsenical weed-killing solution sufficiently strong to kill grass and weeds. The bog was then covered with from 2 to 3 in. of sand and planted 2 weeks later with Early Black cuttings. Growth was very poor,

and many cuttings died. In general, there was a weak growth of vines and a moderate growth of some grasses and weeds. New cuttings planted 1 yr. later grew poorly or not at all. Growth on the no-arsenic areas was much better, although not optimum because the cuttings had been held too long prior to planting. An examination of vines on the arsenic plat showed roots in the top sand, none in the upper 2 in. of muck, and some in the muck below the 2-in. level. In contrast, on the untreated areas roots had formed on the entire length of the cuttings. Analyses of samples of muck collected 2.5 yr. after treatment showed 10 p. p. m. of As_2O_3 in the top 2 in. and in the second 2-in. layers. There were 5 p. p. m. in the 4- to 6-in. layer. The need of plowing deeply before planting to put the treated soil out of reach of the new cuttings is indicated.

Some problems affecting the rooting of hardwood blueberry cuttings, A. E. STENE and E. P. CHRISTOPHER. (R. I. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 259-261).—Coldframes proved more effective than more expensive high box frames for the rooting of blueberry cuttings of the Pioneer, Rubel, and Cabot varieties. Drainage provided by a rock and gravel base gave about the same results as did trays with wire cloth bottoms. Peat alone was a satisfactory rooting medium, with indications that coarse peat was better than fine peat.

Manurial trials with irrigated sultana vines in the Murray Valley, Australia, D. V. WALTERS (*Empire Jour. Expt. Agr.*, 10 (1942), No. 38, pp. 77-88, fig. 1).—In carefully planned experiments with sultana grapes on their own roots, nitrogen proved to be the only fertilizer to give substantial and continued increases in yields of dried fruits. Sulfate of ammonia gave the greatest response, but dried blood containing an equivalent quantity of nitrogen was almost as effective. Cover crops were not consistently effective but had apparent accumulative beneficial effects. Phosphates and potash had no influence on yields.

The climacteric rise in respiration rate of the Fuerte avocado fruit, J. B. BIALE. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 137-142, figs. 2).—The respiratory activity of fruits of the Fuerte avocado at 15° C. was characterized by a rapid acceleration in CO_2 evolution, followed by a marked decrease. At the peak of activity from 120 to 150 mg. of CO_2 are produced by 1 kg. of fruit per hour. This quantity is equivalent to an increase of from 100 to 200 percent over the initial rate. The anaerobic respiration rate was found to be much lower than the aerobic rate with no climacteric rise and no softening of the fruit.

Effect of severity of pruning on top regeneration in citrus trees, S. H. CAMERON and R. W. HODGSON. (Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 67-72, fig. 1).—A study of the rate of top regeneration following light, medium, and heavy pruning of twenty-three 10-year-old citrus trees, representing two varieties of orange and one each of lemon and grapefruit, led to the conclusion that the rate of top regeneration and resumption of fruiting during the first 2 yr. is inversely proportional to the severity of the pruning. Lightly pruned trees reestablished a full complement of leaves during the first year after pruning, while severely pruned trees required 2 yr. or more to produce leaves equal in weight to those removed. Under conditions where tree growth is uniform an equally accurate calculation of the rate of top regeneration can be made on the basis of fresh weight of the above-ground parts of the tree, or of the branches and leaves alone, as upon the total weight of the tree.

An evaluation of some of the factors affecting quality of grapefruit in commercial groves of the Salt River Valley, W. E. MARTIN. (Univ. Ariz.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 59-66, figs. 3).—Based on studies of a

large number of commercial groves and records thereon, it became evident that, in spite of variations in the form of nitrogen used, time of application, and amount applied, nitrogenous material had an increasing effect on production. Manure and calcium nitrate appeared superior to ammonium sulfate. The growing of winter cover crops did not appear markedly beneficial, possibly because of an interference with the uptake of nitrogen by the trees at a time when it was needed to insure production. As yields increased up to about four boxes per tree, quality improved. Beyond this point there was no apparent effect on quality. Summer cover crops as compared with clean culture tended to improve quality. Water supplied in quantities less than 3 acre-ft. seemed to make for poor quality, which in this paper refers to comparative marketability.

Second report upon cold storage of date pollen, W. W. ALDRICH and C. L. CRAWFORD. (U. S. D. A.). (*Date Growers' Inst. Rpt.*, 18 (1941), p. 5).—In continuation of these studies (E. S. R., 81, p. 652), pollen was held successfully from one season to the next in a household refrigerator maintained at about 40° F. The pollen kept well when placed in a small glass container with an open top, this container being placed in a larger jar with an airtight lid and with calcium chloride enclosed to absorb moisture.

Carbohydrate changes in the date palm during the summer, W. W. ALDRICH and T. R. YOUNG, JR. (U. S. D. A. et al.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 110–118, figs. 9).—A high starch content of the palm trunk in early summer, followed by a downward trend during June and July, in nonfruiting palms suggests that during hot weather the respiration of leaves and trunk and the growth of roots, leaves, and trunk draw heavily on reserve carbohydrates. Depletion of starch in the trunk samples of fruiting palms preceding or during fruit ripening indicated that a heavy crop draws on the carbohydrate reserves. With reserves tending to decrease during the June to August or September period, apparently because photosynthesis is less than utilization, it follows that during the October to May period photosynthesis must exceed utilization. Removal of lower leaves when necessary should be done as late in the spring as possible.

Composition of dates as affected by soil fertilizer treatments, W. B. SINCLAIR, E. T. BARTHOLOMEW, and D. E. BLISS. (Calif. Citrus Expt. Sta.). (*Date Growers' Inst. Rpt.*, 18 (1941), pp. 11–16, figs. 3).—Analyses of dates harvested from differentially fertilized Deglet Noor palms revealed little or no difference in chemical composition that could be attributed to the fertilizer treatments. Yields were largest on the plats receiving only ammonium sulfate and lowest on the unfertilized plats. Quality was closely related to the physical environment under which the fruit was grown and also to the type of bunch management used.

Relation of water supply by the date palm to water injury of the fruit, W. W. ALDRICH and D. C. MOORE. (U. S. D. A.). (*Date Growers' Inst. Rpt.*, 17 (1940), pp. 3–5, fig. 1).—Water injury to date fruits following a period of rain or high relative humidity was apparently influenced by the water supply from the palm to the fruit, as well as by water absorbed directly from the air through the skin. A reduction in irrigation water at certain periods was found to reduce the checking of Deglet Noor and calyx loosening of the Saily variety. However, because of possible undesirable effects of reducing water supply to the palms, this practice is not recommended at the present time.

The deterioration of dates, E. M. MEAK. (Univ. Calif.). (*Date Growers' Inst. Rpt.*, 18 (1941), pp. 3–4).—The different types of date deterioration are discussed, with particular attention to microbial spoilage. A slow type of fermentation caused by sugar-tolerant yeasts may occur during the storage of undercured dates and is usually caused by a species of yeast belonging to the

genus *Zygosaccharomyces*, all species of which under study were unusually tolerant to high concentrations of sugar. Two other yeast genera, *Hanseniaspora* and *Candida*, also found in dates, were less tolerant to sugar. The use of cold storage is deemed one of the best methods of reducing microbial spoilage.

Aeration as a factor in reducing fruit spoilage in dates, D. E. BLISS and R. O. BREAM. (Calif. Citrus Expt. Sta.). (*Date Growers' Inst. Rpt.*, 17 (1940), pp. 11-15, figs. 2).—Following fruit thinning, bunches of Deglet Noor dates were separated by the insertion of wire rings which spread the fruit strands apart so as to provide a circular opening of about 8 in. in the center of the bunch. Although the wire ring did not prevent the deposition of moisture on the fruits during periods of rainfall and high relative humidities, it did increase the rate of evaporation of water from the dates after the rain. The manufacture of the rings is described. Paraffined bags placed over the bunches of dates were helpful in reducing losses, particularly when regular-type nonperforated bags were used. Nonparaffined bags tended to keep the outer dates moist and to promote their decay.

Papaya production in the United States, H. P. TRAUB, T. R. ROBINSON, and H. E. STEVENS (*U. S. Dept. Agr. Cir.* 633 (1942), pp. 36, figs. 8).—General information is presented on breeding, pollination requirements, varieties, propagation and planting, soil management, diseases, insects, nematodes, etc. Fertilizer experiments failed to show any marked differences in growth responses, although the highest rates of application tended to give a more sturdy type of plant. As to yield, there was little difference between the low and medium applications but there was a decided increase from the use of heavy applications. A combination of close spacing and high rates of fertilizer application was especially effective in the case of semidwarf varieties. Sugar analyses made by the saccharimeter method failed to show any effect of differential fertilizer treatments but did bring out the fact that the sugar in ripe papayas consists almost entirely of glucose.

Floriculture: Fundamentals and practices, A. LAURIE and V. H. RIES (*New York and London: McGraw-Hill Book Co.*, 1942, pp. VII+496, pl. 1, figs. 67).—Designed primarily as a text for instruction, this book discusses the principles and practices of growing ornamentals and includes the newer developments such as soilless culture and the use of growth-promoting substances.

[Floricultural studies by the Illinois Station] (*Illinois Sta. Rpt.* 1938, pp. 296-298).—Studies by F. F. Weinard, S. W. Hall, and H. B. Dorner include the fertilization of greenhouse roses, effect of K on the splitting of carnation flowers, nutrient solution cultures for greenhouse flowers, and the nutrient and soil reaction needs of the gardenia.

The rose Crimson Rambler and its progenies, C. D. PARIS and T. J. MANEY. (Iowa Expt. Sta.). (*Iowa Acad. Sci. Proc.*, 47 (1940), pp. 65-74).—An examination of records revealed that, up to 1939, 323 varieties of roses have been named which can be traced back to Crimson Rambler parentage. The data are presented chiefly in tabular form.

Control of defoliation in cut holly by use of hormone sprays, J. A. MILBETH and H. HARTMAN. (Oreg. Expt. Sta.). (*Oreg. State Hort. Soc. Ann. Rpt.*, 33 (1941), pp. 42-43).—Dipping holly branches into vats containing a solution of certain proprietary growth-promoting substances was found effective in retarding the dropping of leaves. The holly branches should not be allowed to soak in the liquid and should be drained promptly after immersion. No injury was noted except where concentrations much higher than recommended were used. The dipping was effective over long periods, even when the holly was packed wet or exposed to ethylene contamination such as would occur if holly was stored with ripening fruits.

FORESTRY

Forests of the Illinoian till plain of southeastern Indiana, A. G. CHAPMAN. (U. S. D. A.). (*Ecology*, 23 (1942), No. 2, pp. 189-198, figs. 9).—Studies of the forests of the Illinoian till plain, an area characterized by poor drainage and high water-holding capacity, showed three fairly definite successions of forest cover. The first was the typical upland swamp stand of sweetgum, red maple, and pin oak; the second, a modification of the gum-red maple thickets by the establishment of yellow poplar, black cherry, sugar maple, and shagbark hickory; and, the third, a composition resembling the original forest, brought about by the development of seedlings of beech and, on the better-drained areas, white oak, hickory, black cherry, and sugar maple. The Illinoian till plain has a high potential capacity for producing wood volume, and it is considered practicable to control the stand composition in part by cutting methods and by disturbance of the surface soil.

[**Forestry at the Pennsylvania Station**] (*Pennsylvania Sta. Bul.* 414 (1941), pp. 21-22, fig. 1).—Observations are presented on the progress of the following studies: The comparative value of rapid- and slow-growing chestnut oak for pulpwood, by J. Bethel; direct seeding of Virginia pine on abandoned fields, by W. C. Bramble; the comparative sugar content of the sap of sugar maples growing in the open and in forest stands, by W. E. White, D. D. Stevenson, and H. Triebold; and the preference of deer and rodents for different forest species, by Stevenson.

[**Forestry studies by the Wisconsin Station**] (*Wisconsin Sta. Bul.* 455 (1942), pp. 76-78, figs. 2).—Among studies considered by B. Henry, A. J. Riker, R. V. Olson, S. A. Wilde, and R. O. Rosendahl are a survey of the vigor of red and white pine plantings, the growth of forest seedlings in nutrient solutions, and the inoculation of evergreen seedlings with mycorrhizal fungi.

Twenty years' results of plantation thinning at Biltmore, N. C., E. H. FROTHINGHAM. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 6, pp. 444-452, figs. 5).—Observations in thinning plots established in the fall of 1916 in two stands of pure white pine, one of white and shortleaf pines, and one of white pine and sugar maple suggested that repeated moderate thinnings are profitable, not only for salvage but for increased growth and quality of the remaining trees. In one of the white pine stands the salvage alone from the thinned area was at the rate of $\frac{1}{2}$ cord per acre per year and the annual growth was 1 cord per acre as compared with 1.1 cords in the unthinned stand. The improvement in quality was shown in the fact that in 1936 the trees averaged 8.2 and 5.6 in. d. b. h. in the thinned and unthinned areas, respectively. A too heavy initial thinning yielded results which were not fully as favorable in the second white pine stand. Good results obtained in the mixed stands led to the general conclusion that thinning was advantageous in terms of volume growth and quality.

Crop tree measurements in thinning experiments, W. R. ADAMS and G. L. CHAPMAN. (Vt. Expt. Sta.). (*Jour. Forestry*, 40 (1942), No. 6, pp. 493-498).—A study of data taken in plantations of white pine, jack pine, and red pine showed that the differences in the measurements of trees which are to constitute the final crop in stands of different densities of stocking were not as pronounced as similar measurements for the entire stand. Competition between individuals in the young stand may be shown to be severe when the measurements of all individuals are considered, and relatively minor in character when only the final crop trees are included. The authors suggest that an analysis of measurements following thinning practices should show not only

the increment of the stand as a whole but also the effect of the operation on the increment of selected crop trees.

Seedlings as experimental material in the study of "redwood" in conifers, H. F. WERSHING and I. W. BAILEY (*Jour. Forestry*, 40 (1942), No. 5, pp. 411-414, figs. 4).—Earlier investigations indicated that compression wood or redwood is formed in conifers in response to some form of geotropic stimulus. An examination of small seedling eastern white pine indicated that the hypocotyledonary parts of the stem formed typical redwood and that it may be induced to form during the first growing season and very early in the season. The application of indoleacetic acid to the hypocotyledonary stem of seedlings produced a conspicuous increase in girth both at and below the level of application. The increase was due in part to enlargement of the cortical cells and in part to accelerated cambial activity. The xylem formed by the stimulated cambium is commonly of the redwood type. The auxin application resulted either directly or indirectly in (1) cell enlargement of cortical cells, (2) accelerated cambial activity, and (3) a much modified type of tissue differentiation in the xylem.

Use of Ozark white cedar in the upper Mississippi region, H. A. STEAVENSON and A. F. DODGE. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 5, pp. 415-418).—The Ozark white cedar was found resistant to cedar apple rust and capable of withstanding heat, drought, and other adversities. Studies in a seedling nursery in Missouri and in demonstration plantings in southern Illinois and southern Missouri revealed that the Ozark cedar is unusually difficult to transplant. When compared with the common eastern red cedar the Ozark was an almost complete failure in field plantings. The species was apparently not winter hardy much north of its usual limits near the Arkansas-Missouri line.

Reproduction of ponderosa pine at low elevations in the Sierra Nevada, F. S. BAKER. (Univ. Calif.). (*Jour. Forestry*, 40 (1942), No. 5, pp. 401-404).—In the Sierra Nevada region of California there exists below the 2,000-ft. elevation a belt in which the ponderosa pine grows excellently but its reproduction is very difficult on account of drought. Some reproduction occurs and is facilitated where the surface mineral soil is disturbed. Successful silviculture depends upon the control of competing vegetation, chiefly the chaparral species. The only economical method is to suppress and kill out the brush by maintaining dense stands of pine. Once such stands are attained, their regeneration is possible by any method that promptly frees the reproduction from competition with the parent stands. Such reproduction can be obtained by a number of methods, such as small clear cuttings, shelterwood, a scattered seed tree system, or a selection system with cuts heavy enough to open up the forest fairly radically. Light burning has no place in the program of developing a dense forest.

One-parent heredity tests with loblolly pine, L. S. MINCKLER. [U. S. D. A.]. (*Jour. Forestry*, 40 (1942), No. 6, pp. 505-506).—An analysis of records taken on progenies of seedlings grown from seed taken from individual trees showed no correlation between juvenile height growth and any observable characteristics of the adult mother trees. There were statistically significant differences in both growth and survival of progenies from different parents. The mean growth in four randomized plats of the best progeny was 8.3 ft. and of the poorest 5.4 ft. in 4 yr. Maximum survival was 96 percent and minimum 53 percent 4 yr. after planting.

Effect of mineral fertilizers, peat, and compost on the growth of red pine plantations, S. A. WILDE, F. B. TRENK, and A. R. ALBERT. (Wis. Expt. Sta.). (*Jour. Forestry*, 40 (1942), No. 6, pp. 481-484, fig. 1).—Plantations of red pine 2-2

transplants grown on a depleted outwash sandy soil near Hancock, Wis., showed little benefit from various fertilizer and soil amendments and in some cases distinct injury. A broadcast application of 500 lb. per acre of a complete NPK fertilizer did increase height growth but had no effect on survival. When 1,000 lb. per acre was applied, there were a decreased survival and no well-defined effects on growth. Where materials such as peat, compost, or manure were incorporated with the soil at the time of planting, some of the treatments, particularly alkaline peat and manure, depressed growth. Strongly acid peat and compost were beneficial but the increased height growth, about 12 percent, was not adequate to justify the extra labor and costs. Ill effects are believed due to injury to the young trees by excess nutrient salts, increased weed growth, and a decrease in available water caused by organic remains of high hygroscopicity.

Exposure of roots of shortleaf pine stock, W. H. CUMMINGS (*Jour. Forestry*, 40 (1942), No. 6, pp. 490-492, fig. 1).—The roots of 1-year-old shortleaf pine seedlings were exposed for 5, 15, 45, and 135 min. beyond the minimum essential for transplanting. The day, April 24, was moderately warm and humid, with a cool, gentle breeze prevailing. With increased exposure, readings taken later on the trees showed a marked trend of reduction in the proportion of thrifty trees 2 mo. after planting, in autumn survival, and in first-season increment in height.

Effect of pregermination and radicle damage on first-year development of red oak, L. H. REINEKE. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 4, pp. 346-347).—Red oak acorns were planted (1) ungerminated, (2) germinated with the radicles undamaged, (3) germinated with tips of radicles removed, and (4) germinated with half of the radicle removed. Measurements on seedlings the following spring showed that removing half the radicle increased the tap root diameter significantly above that of plants with uninjured radicles. Removal of half the radicle shortened the tap roots by about 20 percent. The removal of only the tip did not affect root diameter significantly. Apparently the damage to the radicle must be rather severe before it modifies seedling development to any appreciable extent.

Response of chestnut oak reproduction to clear and partial cutting of overstory, J. G. KUENZEL and J. R. MCGUIRE. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 3, pp. 238-243, figs. 4).—The response of chestnut oak reproduction to release by clear cutting and by partial cutting in a second-growth stand of this species in southern Indiana was compared with behavior in an uncut stand during the 10-yr. period beginning with 1929, a year when the catch of chestnut oak seedlings was exceptionally heavy. During this period chestnut oak remained the predominant species in reproduction under all three conditions, composing more than half the total reproduction in 1939. At that time chestnut oak seedlings on the clear-cut area had made an average total height growth of 4.8 ft.; in contrast, those on the partially cut area had grown to an average height of only 0.82 ft., and those on the uncut check plat to one of only 0.48 ft. On the clear-cut area 10 yr. after cutting most of the chestnut oak reproduction was of seedling origin, but 97 percent of all the chestnut oak trees more than 1.0 in. in d. b. h. were sprouts. These sprouts had attained an average height of 21.1 ft., and only a small number of seedlings had successfully established themselves in the overstory.

The drying rate of sugar maple as affected by relative humidity and air velocity, O. W. TORGESON. (U. S. D. A. coop. Univ. Wis.). (*Jour. Forestry*, 40 (1942), No. 3, pp. 218-223, figs. 3).—Air needs were found, in general, to be proportional to drying rates and were least for the lower moisture content stock and for the slower-drying species and materials. An exception to the rule was noted

when relative humidities were increased above approximately 70 percent. Such a procedure reduces drying rate, but requires a higher air velocity to prevent excessive increases in the moisture content of the wood surface and, consequently, an excessive loss of drying time. It is suggested that the most efficient kiln from a drying standpoint would be one equipped to furnish abundant air at the beginning and lesser amounts when the moisture content of the stock decreases as reductions are made in relative humidity.

DISEASES OF PLANTS

Climate in relation to plant diseases, L. E. MELCHERS. (Kans. Expt. Sta.). (*Kans. Acad. Sci. Trans.*, 44 (1941), pp. 172-183, fig. 1).—A general discussion of the subject.

In defense of our food supply: An outline of the strategy of attack that is being devised to combat plant diseases and insect pests, D. G. FLETCHER (*Northwest. Miller*, 210 (1942), No. 2, pp. 7, 30, 31).

How plant breeding programs complicate plant disease problems, N. E. STEVENS. (Univ. Ill.). (*Science*, 95 (1942), No. 2465, pp. 313-316).—This is a general, critical discussion of the problems involved, with specific examples including wheat and hybrid corn. In addition to the two well-recognized methods by which the incidence of losses from diseases and insect pests is strongly influenced, viz, weather changes and introduction, a third, the work of plant breeders, is added. Furthermore, two closely related results of breeding programs are the introduction on a commercial scale of varieties very susceptible to certain, sometimes new, diseases and the modifying effects of new varieties on parasites long known to be commercially important. The number of potential pests is so great and the conditions so complex that no practical tests for disease resistance can cover all possible situations, so "the real test of a new variety is its culture in the hands of ten to twenty thousand farmers."

The Plant Disease Reporter, [May 1 and 15, 1942] (U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 26 (1942), Nos. 8, pp. 175-202; 9, pp. 203-225, figs. 2).—In addition to the host-parasite check-list revision, by F. Weiss (Nos. 8, *Rhodotypos* to *Rondletia*, and 9, *Rosa*), the following items are noted:

No. 8.—Notes on plant diseases in Kansas in 1941, by C. O. Johnston, including important or unusual development of diseases of cereal, forage, and fiber crops, and other diseases of minor importance or of ordinary severity in 1941 (diseases of cereal, forage, and fiber crops, legumes, grasses, trees, and miscellaneous diseases); further notes on the fungi of Nevada, by J. A. Stevenson and W. A. Archer; committee report on ring rot of potatoes in 1941, by T. P. Dykstra et al.; a defoliation of tomatoes in Indiana controlled by spraying with manganese sulfate, by H. R. Thomas; *Diitylenchus dipsaci* on *Trifolium pratense* in New York State, by R. W. Henderson; reports on the development of apple scab in western New York and the Hudson Valley, and apple scab spore discharge delayed in Maryland; and a successful spray for blue mold of tobacco, by P. J. Anderson.

No. 9.—Blueberry stunt, a virus disease, by R. B. Wilcox; a suggested basis for the prediction of wheat leaf rust epiphytotics, including tabulated data on phenological factors in wheat leaf rust development in Oklahoma, 1918 to 1941, by K. S. Chester; wheat leaf rust and other grain diseases in Oklahoma in 1942, by K. S. Chester; additional reports on diseases of small grains, including cereal rusts in Kansas, and grain diseases reported from California; white rot (*Sclerotium cepivorum*) of *Allium* in Louisiana, by E. C. Tims;

wettable Sperguson not effective as a surface disinfectant of sweetpotatoes used for seed, by H. T. Cook and L. L. Harter; and brief notes on diseases in cigar-wrapper tobacco plant beds in Florida in 1942, and pink root of shallots in Louisiana.

[Phytopathological studies by the Illinois Station] (*Illinois Sta. Rpt. 1938*, pp. 62-63, 266-267, 270-271).—Brief reports of results are given relative to adjustment of Ceresan dosages in control of wheat bunt to avoid injury to stored seed, by B. Koehler; and bordeaux still the cheapest and most dependable spray for apples where safe, sulfur fungicides satisfactory for apple scab with a minimum of injury, cherry leaf spot control by copper oxychloride, and apple measles possibly due to boron deficiency, all by H. W. Anderson.

[Phytopathological studies by the Pennsylvania Station] (*Pennsylvania Sta. Bul. 414* (1941), pp. 36-37, 39, 53, 54-55).—Brief reports of experimental results by H. J. Miller, H. W. Thurston Jr., C. C. Wernham, W. S. Beach, and S. Y. Chan include data on a three-part spray schedule for apple scab control without spray injury, and on the value of Elgetol ground sprays against this disease; a second fungus, *Typhula itoana*, causing snow mold of grasses; soil applications of CuSO_4 for controlling damping-off of tomato seedlings; and eradication of mushroom house mold by spraying, Elgetol proving particularly effective and formaldehyde, certain cresylic compounds, and burning S satisfactory for most practical purposes.

[Plant disease work by the South Dakota Station] (*South Dakota Sta. Rpt. 1941*, p. 50).—Observations on fruit diseases reported by N. E. Hansen and W. F. Buchholtz include data on varietal susceptibility of pears to fireblight, and susceptibility of sand cherry (*Prunus besseyi*) seedlings to brown rot, an undetermined leaf spot, and plum pocket.

[Studies of plant diseases by the Wisconsin Station] (*Wisconsin Sta. Bul. 455* (1942), pp. 46-47, 48-52, 62-64, 65-66, 67-68, 71-73, 75-76, figs. 7).—Brief reports by T. C. Allen, J. P. Jolivet, J. C. Walker, R. H. Larson, G. H. Rleman, W. W. Hare, W. J. Hooker, M. Stahmann, F. Smith, K. P. Link, G. W. Kett, J. D. Moore, O. N. Clayton, B. Henry, A. J. Riker, C. A. Richards, and C. S. Moses are included on deep scab of potatoes due to a combination of the common scab and the scab 'gnat'; manganese-deficiency disease of potatoes, beans, and cabbage on burned peat soil, with Zn and Cu deficiency also possibly involved; identification of bacterial ring rot of potatoes; resistance of the Sebago potato variety to yellow dwarf; squash wilt prevalence in the State and resistance of the Table Queen variety; watermelon varieties resistant to wilt in the State; borax spray or dust for control of boron deficiency in garden beets and sugar beets; role of mustard oil in resistance to clubroot; ground sprays useful in apple scab control; sour cherry yellows a virus disease; cherry leaf spot control by low- CuSO_4 bordeaux; and oak wilt due to an undetermined fungus (coop. U. S. D. A.).

Report of Provincial plant pathologist, J. W. EASTHAM (*Brit. Columbia Dept. Agr. Ann. Rpt.*, 36 (1941), pp. 46-51).—Included are progress reports on inspection of nursery stocks for virus infections; little cherry disease, including its virus nature; spray injury to pears; wheat bunt in northern Okanagan, including varietal tests and the effects of different dates of seeding, by W. R. Foster and H. H. Evans; and *Phytophthora cactorum* dark-berry of *Cotoneaster horizontalis*.

Progress of plant pathological research in Bombay, M. N. KAMAT (*Poona Agr. Col. Mag.*, 33 (1941), No. 3, pp. 97-100).

[Phytopathological papers] (*Izv. Gruzinsk. Opytn. Sta. Zashch. Rast.*, Ser. A, *Fitopatol. (Bul. Georgian Expt. Sta. Plant Protect.*, Ser. A, *Phytopathol.*), No. 2 (1940), pp. 339, figs. 63).—The following are included (with briefer notes on various other plant diseases): Materials k mikroflоре tsitrusovykh kul'tur Gruz.

S. S. R. (On the Mycoflora of Citrus in the Georgian S. S. R.), by P. Ī. Nagornyi K. G. Gikashvili (Gulkashvili), and N. A. Sakvarelidze (pp. 3-40, Eng. abs. pp. 37-38); *Bolezni plodov tsitrusovykh pri khraneni i mery bor'by s nimi* (Diseases of Citrus Fruits in Storage and Their Prevention), by L. ĪA. Tsereteli and N. N. Chanturia (pp. 41-73, Eng. abs. pp. 68-68); With Reference to Disinfection of Seed and Roots of *Poncirus trifoliata* [trans. title], by L. I. Tsereteli and N. A. Okrostsvardidze (in Georgian) (pp. 74-83; Russ., Eng. abs., pp. 81-83); With Reference to the Decay of Apples in Storage in the Georgian S. S. R. [trans. title], by L. I. Tsereteli and N. N. Chanturia (in Georgian) (pp. 84-110; Russ., Eng. abs., pp. 100-107); With Reference to the Mycoflora of Ground-Nut Seed [trans. title], by V. A. Vardossanidze and E. M. Eristavi (in Georgian) (pp. 111-154; Russ., Eng. abs., pp. 136-143); With Reference to Java Black Rot of the Sweet-potato in the Georgian S. S. R. [trans. title], by L. A. Kanchaveli (in Georgian) (pp. 155-193; Russ., Eng. abs., pp. 175-193); *Materiāly k izucheniiu Sclerotium rolfsii* Sacc. vzbuditelā "rūzhnoi sklerofśial'noi gnili" (Contributions to the Studies of *Sclerotium rolfsii* Sacc., the Stimulus of "Southern Root Rot"), by E. M. Eristavi and S. ĪA. Īsarlishvili (pp. 194-214, Eng. abs. p. 209); *Materiāly po bolezniām svekly v usloviākh Gruzīnskoī S. S. R.* (Materials on the Diseases of Sugar Beets in the Conditions of the Georgian S. S. R.) (pp. 215-226, Eng. abs. pp. 224-225), and *Vysāvenie stepeni ustoičivosti različnykh sortov fasoli v otnośhenii antraknoza* (*Colletotrichum lindemuthianum* Br. et Cav.) v usloviākh Gruzīnskoī S. S. R. (On the Degree of Susceptibility of Various Varieties of Beans to Anthracnose (*Colletotrichum lindemuthianum* Br. et Cav.) in the Georgian S. S. R.) (pp. 227-252, Eng. abs. pp. 245-247), both by S. ĪA. Īsarlishvili; *Bakterioz na semenakh arakhisa* (Bacterial Diseases on the Seeds of *Arachis*), by M. L. Vachnadze (pp. 253-270, Eng. abs. pp. 267-268); *Studies on Soybean and Peanut Diseases* [trans. title] (in Georgian) (pp. 271-283; Russ., Eng. abs., pp. 278-283), and *Fungi Collected From the Crop Plants in Western Georgia and Diseases Caused by Them* [trans. title] (in Georgian) (pp. 284-298; Russ. abs., pp. 296-298), both by I. I. Shoshiashvili; and *Diseases of Sweetpotatoes in the Georgian S. S. R.* [trans. title], by E. P. Khazaradze (in Georgian) (pp. 299-324; Russ., Eng. abs., pp. 314-323).

A method of mounting cultures of fungi for preservation in the herbarium, M. B. LINN. (Cornell Univ.). (*Phytopathology*, 32 (1942), No. 6, pp. 546-547).—By the method described in detail, petri dish agar cultures are mounted on celluloid sheets cut into squares of a diameter slightly greater than that of the petri dishes. Such specimens may be examined by transmitted light under a cover slip if a drop of water or other mounting fluid is first placed thereon.

Studies on Corticium rolfsii (Sacc.) Curzi (*Sclerotium rolfsii* Sacc.).—I. Cultural characters and perfect stage; II, Mechanism of parasitism, F. L. MILTHORPE (*Linn. Soc. N. S. Wales, Proc.*, 66 (1941), pt. 1-2, pp. 65-75, pl. 1, figs. 7).—In part 1, studies of eight isolates of *S. rolfsii* indicated that the abundance and type of vegetative growth are determined largely by the nature of the medium and the temperature, and the abundance and size of the sclerotia, but not the shape and color, are also affected by these factors. Optimum growth occurred at 30° C., and decreased markedly to 15° and 37°, respectively. The hymenial stage is reported for the first time in Australia, and is referred to *C. rolfsii*. Distinct variations in the growth habit of seven monobasidiosporial cultures are also noted.

In part 2, the pathogenesis of this infection is discussed. The organism is said to penetrate the plant tissues mechanically and to give rise to coenocytic

intra- and intercellular hyphae. Killing of the cytoplasm precedes the invading hyphae by one cell layer, and dissolution of the middle lamellae occurs shortly after entry. Protopectinase and pectinase, but not pectase, are produced and are responsible for the toxic action. There are 17 references.

Elsinoë in Uganda, A. E. JENKINS and A. A. BITANCOURT. (U. S. D. A. et al.). (*Mycologia*, 34 (1942), No. 3, pp. 318-321, fig. 1).—*E. hansfordii* n. sp. is described from leaves and stems of *Scutia myrtina*.

Further notes on the witches' brooms and the substomatal pycnia of Melampsorella, S. M. PADY (*Kans. Acad. Sci. Trans.*, 44 (1941), pp. 190-201, figs. 14).—The results of this work are said to lend support to the previous observations (E. S. R., 85, p. 373) that there are two distinct species of *Melampsorella* as opposed to the monotypic conception of the genus.

A new species of Puccinia on Ocimum adscendens, M. J. THIRUMALACHAR (*Indian Acad. Sci. Proc.*, 14 (1941), No. 5, Sect. B, pp. 466-471, figs. 7).—*P. leiocarpum* n. comb. is described as the telial stage of *Aecidium leiocarpum*.

Virus nomenclature and committees, J. JOHNSON. (Univ. Wis.). (*Chron. Bot.*, 7 (1942), No. 2, pp. 65-66).—This is a report on the history of the International Committee on Virus Nomenclature and the present status of its work, and a brief general discussion of the present chaotic condition of virus nomenclature.

Serological studies on plant viruses, R. MUSHIN (*Austral. Jour. Expt. Biol. and Med. Sci.*, 20 (1942), No. 1, pp. 59-63).—Using the precipitin titration technic, positive flocculation reactions were obtained with the viruses of tomato bushy stunt, ordinary tobacco mosaic and aucuba mosaic, and with the potato viruses X, X + B, aucuba mosaic, and tuber blotch, whereas the viruses of potato spindle tuber, tomato spotted wilt, rose wilt, and strawberry crinkle gave negative results. Cross precipitin tests indicated that of these viruses only the two strains of tobacco mosaic were serologically related. Investigations of the field methods of precipitin testing showed the Chester method (E. S. R., 77, p. 792; 78, p. 493) to be reliable when the optimum antigen-antibody flocculation ratio was applied, whereas the Dunin and Popova method gave inconsistent results.

A darkening technique for inducing virus symptoms in mature as well as in growing leaves, E. M. HILDEBRAND and O. F. CURTIS. (Cornell Univ.). (*Science*, 95 (1942), No. 2467, p. 390).—Using the X disease of peach and placing the infected bud somewhere between the shaded region and the food source (in this case the unshaded leaves carrying on photosynthesis), it was demonstrated that the virus is carried into the shaded leaves along with the elaborated food material, shortening the incubation period as did pruning, defoliation, and girdling (E. S. R., 87, p. 81) and having the additional merit of inducing symptoms also on shoots and leaves that are not growing.

A virus inactivator from yeast, W. N. TAKAHASHI. (Univ. Calif.). (*Science*, 95 (1942), No. 2475, pp. 586-587).—In the work briefly reported a virus inactivator, probably a polysaccharide, was extracted from yeast by autolysis and by autoclaving. Its properties are presented, and a simple method of extracting it is described. Tobacco mosaic virus was used in the study.

New species of Acaulopage and Cochlonema destructive to soil amoebae, C. DRECHSLER. (U. S. D. A.). (*Mycologia*, 34 (1942), No. 3, pp. 274-297, figs. 6).—*A. lasiospora*, *A. gomphoclada*, *C. euryblastum*, all new species, and *C. bactrosporium longius* n. var. are described; utilization by *A. tetraceros* of the amoeba captured by *Zoopage thamnospira* is discussed; and supplementary observations are presented on *Stylopaga cephalote*.

Growing new root systems by soil banking—a promising method of rejuvenating trees attacked by root diseases, A. S. RHOADS (*Phytopathology*, 32 (1942), No. 6, pp. 529-536, figs. 3).—Following a critical discussion of present methods for treating trees attacked by root diseases, attention is called to the usefulness and practical value of a little-known natural method of inarching whereby extensively girdled trees and shrubs may be rejuvenated by soil banking, either alone or combined with previous surgical treatment, disinfection, and aeration, to stimulate development of a new root system above the partially girdled bases. Results from use of this method on citrus trees and Australian pines are described and illustrated, and its applicability to woody plants that readily develop adventitious roots is indicated. This soil-banking method offers the only known practical means of saving old seedling sweet orange trees in which the disease appears to have run its course and which have so far deteriorated that painstaking surgical work is unjustified.

Comments from the study of fungicides in 1941, J. M. HAMILTON. (N. Y. State Expt. Sta.). (*N. Y. State Hort. Soc. Proc.*, 87 (1942), pp. 41-42).

Saving spray materials for the war effort, R. H. DAINES and J. C. CAMPBELL. (*N. J. State Potato Assoc., Hints to Potato Growers*, 23 (1942), No. 1, pp. [2-4]).—Following an interpretation of "saving spray materials" as implying a choice of the best for each purpose and applying under most favorable conditions as to time and method, the authors review 3 years' tests with copper-lime dust on potatoes in which it was found that where applied at night to wet vines, with air movement at a minimum, the amounts of dust could be reduced without sacrificing foliage protection. Further savings could be made by selecting nights when dew is heaviest. Savings in sprays could also be made. For example, when applied in windy weather the coverage is poor and the spray load deposited low, and if sprayed on wet foliage the "run-off" may be excessive. Another important factor is to make sure that all equipment is properly working.

A new fungicide, D. H. PALMITER and J. M. HAMILTON. (N. Y. State Expt. Sta.). (*N. Y. State Hort. Soc. Proc.*, 87 (1942), pp. 207-209).—The most promising organic material from the 1941 fungicidal tests (briefly summarized) is said to be a fluffy black powder, ferric-dimethyldithio-carbamate, referred to as F-D-D-C, which gave apple scab control equal to that of the best dry wettable sulfurs or paste and better control of cedar-apple rust than micronized S. The new fungicide plus cottonseed oil also effectively controlled brown rot on sweet cherries.

Stimulatory and toxic effects of copper sprays on powdery mildews, C. E. YARBWOOD. (Univ. Calif.). (*Amer. Jour. Bot.*, 29 (1942), No. 2, pp. 132-135).—Conidia of *Erysiphe polygoni* germinated well on the surface of 1 percent CuSO₄, but the dried deposit of 0.1 percent bordeaux plus 0.1 percent cottonseed oil on glass slides was toxic to them in water, approximately neutral on dry slides at 100 percent relative humidity, and stimulatory on dry slides at 90 percent. Bordeaux or CuSO₄ added to sucrose agar increased the germinability and length of germ tubes. When light was inhibitory following inoculation, bean plants sprayed with 0.1 percent bordeaux frequently exhibited more mildew development on the upper surface of primary leaves than did unsprayed controls. Bordeaux was more effective as an eradicant than as a protective spray for powdery mildew on bean, and no mildew stimulation was observed when bordeaux was used as an eradicant spray.

The fungicidal and phytocidal properties of some copper xanthates, M. C. GOLDSWORTHY, R. H. CARTER, and E. L. GREEN (*Phytopathology*, 32 (1942), No. 6, pp. 497-504).—Copper xanthates prepared from methyl, ethyl, propyl, butyl, and

isoamyl alcohols were tested in the laboratory against conidia of *Sclerotinia fructicola* and *Glomerella cingulata* and copper ethyl and isoamyl xanthates in the field against *Venturia inaequalis*. In the laboratory these materials largely prevented growth of conidia of *S. fructicola* but not of *G. cingulata*. In the field, control over apple scab was less than that observed from applications of lime-S or Cu phosphate sprays. It appeared from the results of greenhouse and field tests that these materials, per se, were not phytocidal to bean or apple varieties, but that in the presence of arsenicals they promoted arsenical injury.

The fungistatic properties of pyridine carboxylic and aminobenzoic acids, a resonance effect, C. HOFFMAN, T. R. SCHWEITZER, and G. DALBY (*Jour. Amer. Pharm. Assoc.*, 31 (1942), No. 4, pp. 97-99, fig. 1).—"The demonstration that the biological activity of a molecule is related to its structural ability to exist as a resonance hybrid is of interest from many points of view. Sulfanilamide, for example, is *p*-aminobenzenesulfonamide. The isomeric meta and ortho compounds are therapeutically inactive."

Prevalence of seed-borne fungi on cereals in certain seed inspection districts of Canada, F. J. GREANEY and J. E. MACHACEK (*Sci. Agr.*, 22 (1942), No. 7, pp. 419-437).—In seed surveys and pathological tests of wheat, oats, barley, and rye seed (1939-40 crops) many species of fungi and bacteria were isolated. *Alternaria* spp. were by far the most common, but further tests indicated that, apart from the smuts, *Helminthosporium* spp. and *Fusarium* spp. were the most important disease-producing organisms. *Helminthosporium* spp. were much more prevalent in wheat and barley seed, but *Fusarium* spp. were isolated as frequently from oats seed as was *H. avenae*. Seedling blight, root rot, and certain destructive leaf spots of wheat, oats, and barley developed from seeds infected with *H. sativum*, *H. avenae*, and *H. teres*, respectively, and high correlations were found between the percentage of seed infected with the first two fungi and the amount of disease later developing. Disease surveys indicated that certain areas of Canada are much more likely than others to produce seed free, or relatively free, from such organisms. The 1940 data showed that in all districts surveyed wheat seed was comparatively free from smut spores, but a large percentage of oats and barley carried a sufficient spore load to require seed treatment. Treating seed of wheat, oats, and barley infected by *Helminthosporium* and *Fusarium* with a mercurial dust improved seed germination and gave almost complete control of seedling blight and root rot, and of leaf spot and blotch. Extensive soil tests showed that germination of clean, uninjured seed was not improved by seed treatment, but that lightly infected seed treated with an organic mercury dust was as good for sowing as was healthy seed. The results are believed to indicate that annual seed-borne disease surveys are capable of rendering valuable service to seed producers and grain growers.

The inheritance of resistance to *Ustilago nuda*, J. E. LIVINGSTON. (Nebr. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 6, pp. 451-466, figs. 2).—When hybrid barley flowers were inoculated with loose smut, using the partial-vacuum method of Moore (*E. S. R.*, 75, p. 639), infection appeared to be determined by the nature of the embryo rather than by the resistance or the susceptibility of the floral tissues of the female parent on which they were borne. Penetration of the embryo by the mycelium often had a detrimental effect on the development and maturation of the seed. Failure of the method to produce 100 percent infection in the susceptible parent made analysis of the hybrids difficult, but the segregation of inoculated F₁ and F₂ progenies indicated that *Hordeum defolens* and Trebi barley each carry a single dominant factor for resistance and Mis-

souri Early Beardless may possess a weak factor for resistance. There was no evidence of linkage between factors for resistance and those for hoods or six-rownness.

Wheat rusts and wheat scald during the year 1940, T. SĂVULESCU (*Internatl. Bul. Plant Protect. [Roma]*, 15 (1941), Nos. 10, pp. 181M-185M, fig. 1; 11, pp. 201M-205M).—The observations in this communication cover the crop year 1939-40 and refer to Rumania before the territorial changes took place.

Helminthosporium spot of citronella and lemon grass in Guatemala, C. W. DONGE (*Ann. Missouri Bot. Gard.*, 29 (1942), No. 2, pp. 137-140, pl. 1).—This leaf spot of *Cymbopogon nardus* and *C. citratus* was found due to *H. cymbopogi* n. sp., which is described. Preliminary tests indicated that it may be controlled with either bordeaux or lime-S sprays.

A seed-borne mosaic of asparagus bean, *Vigna sesquipedalis*, W. C. SNYDER. (Univ. Calif.). (*Phytopathology*, 32 (1942), No. 6, pp. 518-523, figs. 2).—A mosaic of the Yardlong variety, recovered from a lot of commercial seed, is described. The causal virus was transmitted both by mechanical inoculation of expressed juice and by the pea aphid (*Macrosiphum pist*). It is also seed-borne, in this respect closely resembling the viruses of common bean, cowpea, and soybean mosaics. Thermal inactivation of the virus occurred at 55°-60° C., longevity in vitro was about 2 days, and the dilution end point was nearer 1-1,000 than 1-3,000. Inoculations to cowpea were successful, but only in certain instances were infections of common bean obtained.

Observations on a giant race of the stem celworm, *Anguillulina dipsaci*, attacking broad beans, *Vicia faba* L., T. GOODEY (*Jour. Helminthol.*, 19 (1941), No. 3-4, pp. 114-122).—The author reports having encountered giant forms of this nematode in diseased broadbean during the past few years, first in material from Portugal and later on two occasions in plants grown under ordinary field conditions in England. These forms he describes. In order to test the host range, inoculations were carried out in pot experiments (1933-34) using 18 different legumes. Of these only field pea, garden pea, soybean, and sainfoin became infested, a few lesions with slight invasion of the underlying tissues being noted. A normal-sized race of the nematode from oats is compared.

Studies on root rot of corn in Ontario, J. K. RICHARDSON (*Canad. Jour. Res.*, 20 (1942), No. 4, Sect. C, pp. 241-256, figs. 15).—"Root rot of corn in Ontario is caused primarily by parasitic soil micro-organisms, the most important of which are species of *Pythium*, *Helminthosporium*, and *Fusarium* in that order. The disease causes a decrease in the stand by pre-emergence killing and a dwarfing of the plants by the parasitic invasion and destruction of their roots by the organisms. The pathogens have different optimum soil temperatures, but the lower ranges favor those that cause the most severe damage. The roots of other field crops can be parasitized by the organisms found associated with corn root rot, but their effect on the development of the crop varies greatly. It has been proved under greenhouse conditions that the severity of the disease is greatly reduced if the corn is preceded by cover crops of soybeans and materially increased when preceded by timothy. Other crops tested have an intermediate effect." There are 23 references.

The Ulster method for the examination of flax seed for the presence of seed-borne parasites, A. E. MUSKETT and J. P. MALONE (*Ann. Appl. Biol.*, 28 (1941), No. 1, pp. 8-13, pl. 1).—The sample is thoroughly mixed and the seeds are plated out on 2 percent malt extract agar into Petri dishes, 10 seeds being spaced equidistantly in each and with a total of 100 seeds for general results but with 500 for more accurate estimation of degree of infection. The dishes are then incubated at 22° C., and after 5 days the medium around each seed is

examined for parasitic organisms. Satisfactory results have been obtained by use of this method. Examples are cited where it has been possible to determine the country or origin of flaxseed, and indications have been obtained suggesting the suitability of the method for distinguishing between new and old seeds.

Peanut leafspot and leafhopper control, L. I. MILLER (*Virginia Sta. Bul.* 338 (1942), pp. 24, figs. 7).—Leaf spots (*Cercospora* spp.) are said to be the most common and among the most destructive peanut diseases and the leafhopper (*Empoasca fabae*) one of the most injurious insect pests, the former causing substantial losses annually and the latter causing injuries only spasmodically. Experiments on the control of these two pests were conducted by the station on 70 farms in the principal peanut-producing counties of Virginia (1938-41), and the results have indicated that they can be controlled and that profitable yield increases may be obtained with 3-4 applications of finely ground S dust at 2-week intervals. The cost of dusting an acre, including rental for the duster and costs of materials and labor, is said to be about \$3. From demonstration tests (3 applications) on 30 farms, the average increase in yield of nuts was 481 lb. per acre (extremes, 238 and 834 lb.). In yields of hay, increases of 526-3,419 lb. per acre were also obtained from tests on 7 farms, the average being 1,674 lb. per acre. Nuts and hay of better quality also followed use of the S dust, and treated plants matured 5-10 days later and could be held in the ground longer without serious loss of nuts through shredding. These features proved of great advantage to growers faced with labor shortages at digging time.

Mancha preta ou cercosporiose do amendoim (*Cercospora personata* (B. & C.) Ellis) [Peanut leaf spot or cercosporiose (*C. personata*)], A. TOCCHETTO (*Rev. Agron. [Brazil]*, 5 (1941), No. 57 pp. 501-502, figs. 4).—A note on the presence of this disease and its control in Brazil.

An epiphytotic of potato blight, J. B. MARCHIONATTO (*Internatl. Bul. Plant Protect. [Roma]*, 15 (1941), No. 10, p. 181M).—Note on *Phytophthora infestans* in the eastern part of Argentina.

Experiments for control of potato late blight in an epidemic year, G. D. RUEHELE. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 54 (1941), pp. 106-108).—*Phytophthora infestans* blight is said to have become the most important potato disease in the Homestead (Fla.) area, though prior to 1937-38 *Alternaria solani* blight had been considered the more important. In recent tests all sprays and dusts used caused a longer duration of vine growth and significantly increased the yields of marketable tubers, but sprays were more effective for blight control than the dusts. Further details are tabulated and briefly discussed.

New blight-resistant potato varieties, K. SNELL (*Internatl. Bul. Plant Protect. [Roma]*, 15 (1941), No. 11, p. 201M).—Note on three potato varieties (Erika, Frühnudel, and Robusta) said to be resistant to *Phytophthora infestans*.

The susceptibility to leaf roll of certain potato varieties and its effect on their yield, J. B. LOUGHNANE ([*Irish Free State*] *Dept. Agr. Jour.*, 38 (1941), No. 1, pp. 48-67, pls. 3).—Following a discussion of the literature (7 references) on varietal susceptibility to leaf roll, its effects on the vigor of some of the newer potato varieties are described and those used in the 2 years' experimental work are placed in three groups on this basis. Counts (1937-38) of the prevalence of *Myzus persicae* and data on the prevalence of primary leaf roll led to the conclusion that the period when most of the latter appeared coincided with the date of maximum aphid infestation. Reduction in yield of a variety was in direct proportion to the reduction in vigor of that variety by leaf roll, and the varieties used are grouped according to the reduction in yield due to this virus disease.

Bacterial ring rot of potatoes from the standpoint of quarantine and standardization, C. H. METZGER (*Calif. Dept. Agr. Spec. Pub.* 186 (1941), pp. 9-16).—This is an address presenting a summary of current knowledge on this disease and its control, with discussions by various individuals.

Scabbia violosa delle patate [Potato skin spot], V. BONGINI (*Bol. Lab. Sper. e R. Osserv. Fitopat.* [Torino], 17 (1940), No. 1-4, pp. 25-38, pls. 2).—It is concluded from this review and experimental study that the principal cause of the disease is *Oospora pustulans*. Secondary invaders encountered included various other fungi and nematodes. There are 19 references.

Determination of death in the larvae of the potato root eelworm, A. E. W. BORD (*Nature* [London], 148 (1941), No. 3765, pp. 782-783).—It is often exceedingly difficult to determine whether nematode larvae are dead or only dormant. It was found that staining larvae of the potato strain of *Heterodera schachtii* with a solution of 0.025 gm. of I in 100 cc. of 1 percent KI solution differentiated living from dead individuals.

O virus Y, uma das principais causas da degenerescencia das batatinhas no Estado de S. Paulo [Virus Y, one of the chief causes of potato degeneration in the State of São Paulo], K. SILBERSCHMIDT and M. KRAMER (*Biologico*, 8 (1942), No. 2, pp. 39-46, pl. 1; *Eng. abs.*, pp. 45-46).—By passage through six tuber generations, the dissemination of this disease was verified in two experimental plats of the Elgenheimer variety—one on high and one on low land. The potato degeneration diseases in São Paulo, said to be due largely to the Y virus, were disseminated more rapidly at the low than at the high elevation. *Nicotiana glutinosa* and *N. tabacum* were used as indicator plants in the inoculation experiments, and the symptoms induced are described.

The nutrition of turnips, R. M. WOODMAN (*Ann. Appl. Biol.*, 28 (1941), No. 1, pp. 1-7, pl. 1).—"The influence of variations in the supply of some inorganic nutrients on the growth of the turnip in sand was investigated. Deficiency symptoms were noted, and a statistical comparison of yields was made. Progressive diminution of available nitrogen led to a progressive diminution in yield. Similar diminution in available phosphorus led at first, in strong contrast to lettuce, to a continuous rise in yield and a less chlorotic plant, then at a relatively low concentration of phosphorus to an optimum yield, and finally to a rapid decrease in yield. Potassium deficiency gave a characteristic gray-green scorch and limpness of the foliage, together with leaf drop. The yield was not decreased greatly by a reduction of available potassium until a fairly low level was reached. Absence of boron resulted in a characteristic wastage of the foliage, and ultimately in the death of the plant; the turnips were tiny, rough-sided, and had a tendency to rot. The presence of 0.0681 p. p. m. of boron, as borax, yielded plants of normal size, health, and appearance."

Moléstias da cana de açúcar em Pernambuco [Diseases of sugarcane in Pernambuco], A. R. CAMPOS (*Bol. Sec. Agr., Indús. e Com.* [Pernambuco], 8 (1941), No. 2, pp. 169-174, pls. 4).—Considered are a root rot, and diseases due to *Leptosphaeria sacchari*, *Thielaviopsis paradoxa*, *Fumago sacchari*, *Colletotrichum falcatum*, and *Trichosphaeria sacchari*.

Tift Sudan, a utopia grass for Southeast, G. W. BURTON. (U. S. D. A. and Ga. Coastal Plain and Ga. Expt. Stas.). (*South. Seedsman*, 5 (1942), No. 1, pp. 7, 31, 35, figs. 2).—This new variety, developed by hybridizing Sudan grass strains susceptible to foliage diseases with the disease-resistant Leoti sorghum, is said to be disease-resistant, to yield twofold in hay over common Sudan grass, and to provide excellent pasturage. It contains more of the poisonous prussic acid than common Sudan grass, but in the humid Southwest where sorghums have been grazed there is little likelihood of livestock poisoning from grazing Tift Sudan. Limited seedstocks are said to be available.

Certain enzymatic activities of normal and mosaic infected tobacco plants, F. L. WYND. (Univ. Ill.). (*Jour. Gen. Physiol.*, 25 (1942), No. 4, pp. 649-661, figs. 3).—Leaves of mosaic-inoculated tobacco plants exhibited a great decrease relative to normal tissue in oxygenase and peroxidase activities on the sixth day, though younger leaves showed this minimum at a progressively later date; and great increases were attained at 14-18 days, followed by a second decrease. Catalase exhibited increased activity, reaching a maximum about the eighth day, with a second one at 16-18 days. Invertase reached a minimum relative to controls about the eighth day, with a second one approached at 16-18 days. These data indicate profound physiological disturbances in infected plants many days before the leaf juice attains an infectious virus concentration. It is suggested that these activities could hardly be due to metabolic activities of the virus particles themselves. Since infectivity is attained only after a period of profound physiological disturbance, it is believed possible that the virus protein develops as a product of abnormal metabolism. There are 25 references.

Control of seedling diseases of sugar beets in Montana, M. M. AFANASIEV and H. E. MORRIS. (Mont. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 6, pp. 477-486, figs. 2).—Seed treatments alone proved only slightly beneficial for controlling the seedling diseases of sugar beets due chiefly to *Phoma betae*, *Pythium* spp. and other soil-borne Phycomycetes, and *Rhizoctonia* spp., but soil treatments, regardless of seed treatments, proved highly important. Plots with the most complete soil treatments, viz, NPM, N/2 P, N/2 P, NPM+Ca(OH)₂, and NP+Ca(OH)₂ (N=nitrates, P=phosphates, and M=manure, and N/2 and N/3 mean nitrates applied in two and three applications, respectively), produced the minimum of seedling disease and the highest yields and stands. Plots treated with NP, N/3 P, and MP had fairly good yields and stands, but also considerable amounts of seedling diseases. The plots with unbalanced soil amendments (N, P, and M) all exhibited a high amount of seedling disease, and the yields and stands also were poor except where treated with manure. Control plots and those treated only with Ca(OH)₂ had the highest amounts of seedling diseases and the poorest yields and stands. It is concluded that seedling diseases of sugar beets in heavy irrigated Montana soils can be efficiently controlled with concomitant good stands and high yields by creating conditions conducive to rapid and healthful development of young sugar beets through sufficient and balanced fertilization and improvement of the physical condition of the soil.

Sorghastrum, host of an undescribed smut, A. B. MASSEY and G. L. ZUNDEL. (Va. A. and M. Col. and Pa. State Col.). (*Phytopathology*, 32 (1942), No. 6, pp. 544-546).—A high incidence of head smut found on a small colony of *S. elliotti* near Chatham, Va., proved to be an undescribed species of *Sphacelotheca*, here described and named *S. sorghastri*. The host is said not to have been previously reported in Virginia outside of the Coastal Plain, this station extending its range 125 miles into the Piedmont. *Sorghastrum nutans* is common over the State.

The mechanism of spore dispersal in Peronospora tabacina and certain other downy mildew fungi, J. A. PINCKARD. (Va. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 6, pp. 505-511, figs. 2).—Sporangial dispersal, caused by changes in moisture content of the air, are described for *P. tabacina*, *P. parastitica*, *P. geranii*, *P. halstedii*, and *P. effusa*. Freshly formed sporangioophores bearing sporangia of *P. tabacina*, when examined in air and under conditions of changing water vapor pressure, exhibit violent hygroscopic movement and sporangial discharge. If no water vapor deficit exists, no movement occurs and the sporangia

proliferate in place. The mechanics of sporangial discharge may be described as either the result of entanglement of sporangiophore branchlets and/or the ejection of sporangia by hygroscopic forces applied at the base of the sporangia when a water-vapor pressure deficit exists. Since several other members of the genus *Peronospora* were observed to react similarly, it appears that this mechanism has a definite function in the life history of these organisms and that it serves to disperse the sporangia during the most favorable period for sporangial dissemination and germination. Sporangial dispersal among the Peronosporales does not, as was commonly believed, depend on the mechanical action of wind and rain, but on water vapor pressure deficit at maturity.

Cold injury of flue-cured tobacco seedlings, J. A. PINCKARD and L. S. BOZOVANSKY. (Va. and Miss. Expt. Stas.). (*Phytopathology*, 32 (1942), No. 6, pp. 512-517, figs. 4).—Incipient cold injury to seedlings of both the burley and flue-cured types of tobacco resulted in bleaching of the bud leaves. Common in early spring, it appears to be induced by 2-3 hours' exposure at 24°-26°F., or 15-16 hours' exposure at 29°-32°. Typical symptoms of the so-called "white bud" disease, a phase of cold injury, appeared 4-5 days after exposure to these temperatures. The first tissues in tobacco leaves to succumb were those at the margins of very young leaves, which appeared true for both seedlings and older plants. More intense cold destroyed the apical meristem in both young and old plants, but cold injury to mature leaves resulted in irregular patterns and blanching.

Boron nutrition of cauliflower in relation to browning, C. H. DEARBORN ([New York] *Cornell Sta. Bul.* 778 (1942), pp. 29, figs. 16).—A survey (fall of 1934) of about 150 farms in the Catskill Mountain area covering 443 acres of cauliflower revealed about 30 percent unfit for marketing because of browning of the heads. No clue as to the cause being found, field experiments (coop. Delaware County Farm Bureau) were started in 1935 and continued through 1939, along with greenhouse tests on soil from affected fields and on culture solutions, and with histological and microchemical studies. The various symptoms described include a bitter flavor both in the raw and cooked state, even in the absence of browning. Preliminary tests with six minor elements indicated that where borax had been mixed with the fertilizer and broadcast or applied in trenches near the rows, surface browning was satisfactorily prevented. Further studies confirmed these results, and all the B-deficiency symptoms developing in the greenhouse were identical with those observed in the field. Furthermore, the yield data for weight of head showed that plants supplied with borax, at any rate used, produced heads significantly larger than those without borax. In a greenhouse test whole plants without and with borax (at 10 lb. per acre) contained nearly the same amount of dry matter, but their fresh weight differed by 14.5 percent and that of the heads alone by about 44 percent in favor of the treatment. When the dry weight of the heads was expressed as percentage of their fresh weight it was seen that there was a higher proportion of dry matter in the heads of B-deficient than of normal plants, indicating that an abundant supply of carbohydrates was translocated to such heads.

Differences of opinion are noted as to where B deficiency is first manifested in green plants, but in this study they were first observed in the parenchyma cells of the pith and the cortex of the stem. Microchemical tests for reducing sugars in the root and head of both B-deficient and normal plants revealed that in all cases the amounts of Cu reduced in the B-deficient roots and heads were far in excess of those reduced in the tissues of normal plants. There is believed little reason to doubt that in advanced stages of B deficiency disorganization within the conducting system has occurred, but the fact that sugars are abundant when the intercellular spaces are being filled with the translucent mucilaginous

substance is considered evidence that the supply of energy materials is not exhausted in these areas. Further details of the work are presented, and comparisons with results of investigations on B deficiencies by others are given.

La "viruela" del apio en la provincia de Mendoza [Celery late blight in Mendoza Province], R. E. PONTIS (*Bol. Agr. [Argentina]*, 9 (1941), No. 1-3, pp. 54-56, fig. 1).—This is a note on *Septoria apii graveolentis* in Argentina.

Mosaic of celery caused by the virus of alfalfa mosaic, W. C. SNYDER and S. RICH. (Univ. Calif.). (*Phytopathology*, 32 (1942), No. 6, pp. 537-539, fig. 1).—Celery mosaic, consisting of a mild to conspicuous yellow-green mottle, was induced in greenhouse tests by mechanical inoculations of the Golden Self Blanching variety with extracted juice from plants infected with the alfalfa mosaic virus. Four California sources were used, with properties determined as follows: Temperature inactivation point, 60°-65° C.; dilution end point, 1-2,000 to 1-3,000; and longevity in vitro, 3-5 days. Transmission by the pea aphid (*Illinoia pisi*) was demonstrated. A direct relationship in the field between alfalfa mosaic and this caliclike mosaic of celery is suggested.

Structure and germination of *Septoria* spores, H. G. MACMILLAN and O. A. PLUNKETT. (U. S. D. A. and Univ. Calif.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 10, pp. 547-559, pls. 2).—The authors studied and report in detail on the spore structure, growth, and germination in *S. apii-graveolentis* from cultivated and escaped celery, and the meaning and significance of terms applied to the spores, such as "septation," "guttula," and "maturity," are analyzed. Assuming that the spores of this species reveal the nature of *Septoria* spores in general, the existent inadequacy and confusion in the descriptions of species in the genus are discussed, and suggestions are offered for greater precision in observation and description. It is concluded that *S. apii-graveolentis* spores are mature when they consist of four cells (3-septate). Septation in the spores is caused by the abutting membranes of contiguous cells within the integument, and there is no wall or true septum within the mature spore. The guttulae of *Septoria* spores in descriptive mycological literature are bright spots produced by lens action on the clear portions within the cells. Germination is accompanied by cell proliferation, usually by division of the end cells of the spore. Changes in the appearance of the cell contents occur with progressive stages of germination. There are 16 references.

Celery spraying experiments at the Everglades Experiment Station, G. R. TOWNSEND. (Fla. Expt. Sta.). (*Fla. State Hort. Soc. Proc.*, 54 (1941), pp. 130-131).—In tests conducted since 1930 bordeaux is said to have proved equal or superior to all the insoluble coppers and several Cu-lime dust mixtures. Some of the so-called bordeaux injury was found due to excess lime, and a 4-2-50 formula is thus recommended.

The perfect stage of *Phomopsis vexans*, L. O. GRATZ. (Fla. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 6, pp. 540-542, figs. 2).—Comparative study of numerous isolates of *P. vexans*, cause of "tip-over" disease of eggplants, yielded several which produced typical perithecia, asci, and ascospores in culture. These isolates were pathogenic for eggplants. The perfect stage not having been previously described, the binomial *Diaporthe vexans* n. comb. is proposed for it.

Influence of temperature on the expression of big-vein symptoms in lettuce, R. C. THOMPSON and S. P. DOOLITTLE. (U. S. D. A.). (*Phytopathology*, 32 (1942), No. 6, pp. 542-544, fig. 1).—Symptom expression was found to be almost if not entirely masked by high temperature (day, 85°-75° F.; night, 50°-60°). Typical symptoms appeared at temperatures of 50°-60° by day and 45°-50° by night. Leaves both with typical symptoms and with no evidence of the disease were produced on the same plants by alternate periods of high and

low temperature. Changes in temperature appeared to have no effect on the presence or absence of the symptoms after the leaves had completed their grand period of growth.

Should chemically treated pea seed be inoculated? G. L. McNEW and A. W. HOFER. (N. Y. State Expt. Sta.). (*Canner*, 94 (1942), No. 19, pp. 11-12, 24, fig. 1).—"The ordinary copper and mercury treatments for pea seed are so toxic to bacteria that they prevent successful inoculation with nodule bacteria. Seed treated with Spergon was successfully inoculated in repeated tests in the greenhouse, but the results have not yet been confirmed by field observation. Even Spergon injures the bacteria, so only strong, viable cultures should be used, and these should be applied immediately before planting to seed treated with not more than 1.5 oz. of chemical per bushel."

Un marciume dei frutti del peperone da "Botrytis" tipo "vulgaris" Fr. [A rot of pepper fruit due to a *Botrytis vulgaris*-type fungus], G. OSSINI (*Bol. Lab. Sper. e. R. Osserv. Fitopat.* [Torino], 17 (1940), No. 1-4, pp. 52-61, pl. 1; *Ger. abs.*, p. 61).—The fruit rot of *Capsicum annuum* here studied is shown to be due to a *Botrytis* with sclerotial stage.

Virus diseases of tomato, P. E. M. CLINCH ([*Irish Free State*] *Dept. Agr. Jour.*, 38 (1941), No. 1, pp. 24-47, pls. 7).—Descriptions are given of common tomato mosaic, single-virus streak, aucuba mosaic, enation mosaic, double-virus streak, and spotted wilt, and the relationships of the underlying viruses are indicated and their properties and modes of transmission presented. There are 30 references.

"Dunking" tomatoes for their health, G. B. REYNARD. (U. S. D. A.). (*South. Seedsman*, 5 (1942), No. 1, pp. 10, 30, figs. 5).—The author describes a method successfully used to test the resistance of seedling tomato plants to gray leaf spot (*Stemphylium*) and early blight (*Alternaria*) which on a few yards of greenhouse bench in winter tests supplements acres of summer trials. Liquid cultures of the fungi are thoroughly mixed in an electric stirrer until broken into fine particles, when the potted seedlings are dipped therein, thus covering both leaves and stems with thousands of particles of the fungi. After 2 days in a moist chamber the plants are then placed on greenhouse benches for observation. Field use of this technic was found to give comparable results, enabling the rapid discovery of resistant seedlings and elimination of susceptible ones in the breeding and selection program.

The development of wilt resistant tomatoes, C. M. TUCKER. (Univ. Mo.) (*Missouri Acad. Sci. Proc.*, 7 (1942), No. 4, pp. 90-91).—An abstract.

On the occurrence of the chrysanthemum eelworm, *Aphelenchoides rit-zema-bosi*, in a tomato fruit, T. GOODEY and S. H. BENNETT (*Jour. Helminthol.*, 19 (1941), No. 3-4, pp. 123-126).—This is a brief note on the occurrence of this nematode within the tissues of tomato fruits. Though well known as a leaf parasite, it is believed not to have been previously reported from a fruit.

Injury to tomato seed in disinfection, J. H. MILLER and R. Grogan. (Univ. Ga.). (*Phytopathology*, 32 (1942), No. 6, pp. 524-528, figs. 2).—The tests reported indicate that when the ratio between amount of seed and volume of treating solution is increased above 1:8 germination is progressively impaired. The curves for Ceresan and HgCl₂ were not significantly separated in one test and in a second the trends were reversed, so one cannot logically predict a difference in germination depression between the two from the results of this study. Both of them, however, showed the downward trend of the curves in wide ratios. The ratio of 1:8 produced complete disinfection without a too-serious drop in germination.

Fruit diseases in 1941, W. D. MILLS. (Cornell Univ.). (*N. Y. State Hort. Soc. Proc.*, 87 (1942), pp. 8-15).—A brief seasonal survey of diseases of pome, stone, and small fruits for New York State.

Apple scab development, H. W. ANDERSON (*Ill. Hort.*, 31 (1942), No. 2, p. [1]).—Perithecia with mature ascospores are recorded for February 5, 1942, said to be the earliest record for Illinois.

Prebloom sprays for apple scab control, H. W. ANDERSON (*Ill. Hort.*, 31 (1942), No. 2, pp. [1-2]).—The value of two prebloom sprays is stressed, and from the standpoint of economy and efficiency a 1-50 lime-S is recommended for the prepink application, with a microfine S such as a flotation paste for the pink spray.

Ground sprays as supplementary scab control measure, A. B. GROVES. (Va. Expt. Sta.). (*Va. Fruit*, 30 (1942), No. 4, pp. 13-14).—A general discussion and evaluation of ground sprays for apple scab control.

Is there danger of reducing the set of fruit by blossom-time sprays or dusts for control of scab, rust, or fire-blight? **F. H. LEWIS.** (Cornell Univ.). (*N. Y. State Hort. Soc. Proc.*, 87 (1942), pp. 15-24).—The experimental data (1939-41) presented are believed to leave little doubt that spraying or dusting in bloom with the materials used (S dust and spray, dilute lime-S, flotation S, bordeaux spray, Thylox flotation paste, lime-hydrated spray lime, and Cu-lime dust) will reduce the fruit set in many cases and may have an effect on fruit size. Lime-S appeared to cause the greatest reduction in set. Various minor or exceptional effects are discussed, and it is concluded that from present knowledge the individual grower should balance the danger of greater loss from fruit diseases if a bloom application is omitted against the possible reduction in fruit set (in some cases beneficial) and the risk of russetting.

Some factors affecting apple scald disease, R. M. SMOCK and F. W. SOUTHWICK. (Cornell Univ.). (*Science*, 95 (1942), No. 2475, pp. 576-577).—Two years' results on the Rhode Island Greening variety are reported to indicate that coating the fruit with a wax emulsion (Brytene 489 AM) gives considerable promise in scald control. Progress has also been made in "air conditioning" the storage atmosphere to rid it of the harmful volatiles responsible for scald.

Experiments with arsenite sprays to eradicate *Sclerotinia laxa* in stone-fruit trees as a means of controlling the brown rot disease in blossoms, E. E. WILSON. (Calif. Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 64 (1942), No. 10, pp. 561-594, figs. 6).—A serious blossom blight due to this fungus is reported as common on several stone-fruit species in California. On entering the blossoms it proceeds to invade the twigs, thus destroying much of the fruiting wood. Since the only known hold-over stage of the fungus occurs on the tree, an opportunity was given to test the possibility of reducing the survival level by eradicant fungicides. In experiments over a 3-yr. period involving about 161 separate trials in 15 counties and under great variations in temperature and rainfall, dormant spraying of brown rot-infected apricot, almond, prune, and plum trees with aqueous suspensions of monocalcium arsenite was found to prevent development of an extremely high percentage of the sporodochia—source of the conidia causing blossom infection in the spring—because soluble As from the spray film penetrated the hold-over twigs sufficiently to kill most of the mycelium bearing them. The Na and Zn arsenites used were erratic in their effect on the fungus. The Ca salt also proved capable of destroying sporodochia present when the spray was applied. Marked decreases in blossom infection attended high degrees of sporodochial suppression. The concentration of the arsenite in the spray and timing of applications with respect to efficacy against the fungus and injury to the tree are discussed in detail. Almonds proved very sus-

ceptible to arsenite injury, whereas the apricot and plum varieties tested were much less so.

Brown rot of peach and its control, R. H. DAINES (*New Jersey Stat. Cir.* 434 (1942), pp. 8, figs. 3).—This is an informational circular embodying the essentials of present knowledge on the disease and its control.

How to prevent destruction of New York State peach orchards by the new yellow-red virus disease, E. M. HILDEBRAND and D. H. PALMITER. (Cornell Univ. and N. Y. State Expt. Sta.). (*N. Y. State Hort. Soc. Proc.*, 87 (1942), pp. 34-40).—This is a general review of present knowledge on this virus disease, with the final advice to buy trees from reliable nurseries, isolate young plantings a minimum of 500 ft. from chokecherries, and destroy all chokecherries within 500 ft. of bearing peach orchards.

Crystalline versus monohydrated zinc sulphate as a preventive against arsenical injury on peaches, R. H. HURT (*Va. State Hort. Soc. Rpt.*, 46 (1941), pp. 48-51).—This is a note summarizing several years' tests with $ZnSO_4$ and lime, with formulas, for control of arsenical injury. Experimental tests and commercial use indicated that there is very little difference between the results with crystalline v. the monohydrated Zn salt.

Cranberry disease control in war time, R. B. WILCOX. (U. S. D. A.) (*Amer. Cranberry Growers' Assoc., Proc. Ann. Mtg.*, 72 (1942), pp. 19-22).—This is a general discussion, with suggestions especially pertinent to the wartime situation.

Studies in strawberry virus diseases, IV, V (*Jour. Pomol. and Hort. Sci.*, 19 (1942), No. 3-4, pp. 212-242, pls. 2, figs. 4).—This is a continuation of previous studies.¹

IV. Symptom expression of yellow-edge in the variety Royal Sovereign, M. E. KING and R. V. HARRIS (pp. 212-226).—The symptom expression of yellow-edge is said to be closely correlated with the interaction of temperature and soil moisture, with three phases: (1) In early spring the soil moisture is adequate but the temperature is not high enough for symptom expression. (2) An intermediate phase begins with the minimum air temperature at about 60° F. at a time the soil moisture is often too low for symptom development, and this accounts for the occasional and merely temporary appearance of symptoms during May and June. (3) The final phase supervenes as the temperature falls in late summer and autumn, when, although the soil may be saturated, the symptoms gradually fade away as the weather becomes colder. Experiments have shown that there is no simple nutritional explanation for the difference in intensity of symptoms among individual plants. In a field test, the results suggested that a mixture of virus strains might have been present but that no resistance was exhibited by mildly affected plants towards infection with the more virulent strains. The first result of yellow-edge infection is a flattening of the plants, followed later by reduction in size, these manifestations increasing with intensity of symptoms. Affected plants also show considerable reduction in development of runners. The symptoms begin to show 1-2 weeks after environmental conditions are such that air temperature is above 60° and soil moisture is plentiful. These periods, when symptoms are most easily detected and when roguing should be done, usually occur in England in June, and, especially, in September and October.

V. The use of *Fragaria vesca* L. as an indicator of yellow-edge and crinkle, R. V. HARRIS and M. E. KING (pp. 227-242).—The method of inarching stolons with stolons or with leaf petioles was used to determine the virus content of selected stocks of a number of strawberry varieties by inarching to healthy indicator plants. Of several possible indicators tried, *F. vesca* proved the most satisfactory. Certain selections of the susceptible Royal Sovereign, Sir Joseph

¹ East Malling [Kent] Res. Sta. Ann. Rpt., 24 (1936), pp. 212-221, pls. 3, fig. 1.

Paxton, and King George were found to induce no visible reaction in *F. vesca* and were thus considered virus-free. Selections of certain varieties exhibiting no symptoms of infection themselves transmitted disease when grafted to *F. vesca*, in which symptoms developed. Nearly all the selections of such carrier varieties induced symptoms in *F. vesca* and were, therefore, not virus-free, but one strain of Huxley Giant appeared to be free from viruses and is being propagated for further trials. Negative results were obtained as to seed transmission.

The influence of the root on chlorosis of the Concord grape, F. B. WANN and A. WILSON. (Utah State Agr. Col.). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 17 (1939-40), p. 2).—An abstract.

Notes on Clitocybe root rot of bananas and other plants in Florida, A. S. RHOADS. (Fla. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 6, pp. 487-496, figs. 3).—This toadstool root rot, due to *C. tabescens*, which has been found to be widespread in occurrence throughout Florida and frequently very destructive to a large variety of native, fruit, and ornamental trees, and shrubs and vines, is reported. The symptoms, described and illustrated, agree closely with those of a corm rot of bananas (attributed to *Clitocybe* sp.) reported as increasingly prevalent in New South Wales where plantings are extended to newly cleared hardwood forest land. Notes are also included on the widespread loss of a number of trees and other plants, mostly exotic and including a number of uncommon subtropical ones, from attack by *C. tabescens* in the same area where this disease proved so destructive to bananas.

Color handbook of citrus diseases, L. J. KLOTZ and H. S. FAWCETT (*Berkeley: Univ. Calif. Press*, 1941, pp. [3]+90, pls. 40).—"The purpose of this handbook is to provide citrus growers, packing-house men, horticultural inspectors, and extension workers with a ready means of identifying the various diseases that attack citrus, by describing and illustrating their effects, and to give essential information on their control."

Phomopsis sp. coleccionado sobre plantas citricas em Piracicaba e Guarujá [Phomopsis sp. collected on citrus plants in Piracicaba and Guarujá], R. AVERNA SACCÁ (*Rev. Agr. [Brazil]*, 16 (1941), No. 9-10, pp. 455-460, figs. 4).—The author reports studies of a *Phomopsis* found on *Citrus* spp. not identifiable by him with any previously named species on these hosts, together with a brief note on a sterile mycelium found on orange fruit.

A leprose da laranjeira [Citrus leprosis], A. TOCCHETTO (*Rev. Agron. [Brazil]*, 5 (1941), No. 59, pp. 663-664, figs. 3).—A note on this insect-transmitted virus disease and its control in Brazil.

La lucha contra Sphaceloma australis, parásito del mandarino en la Provincia de Santa Fe [Control of *S. australis*, parasite of mandarin oranges in Santa Fé Province, Argentina], E. SCHIEL (*Rev. Argentina Agron.*, 9 (1942), No. 1, pp. 19-27; *Eng. abs.*, p. 27).—From the trials reported, it is concluded that two bordeaux sprays, the first just before blooming and the second when at least three-fourths of the petals have fallen, will be effective for commercial control.

A review of our knowledge of [citrus] melanose and its control, R. S. EDSALL (*Fla. State Hort. Soc. Proc.*, 54 (1941), pp. 26-33, figs. 2).

The hare and the tortoise of citrus stem-end rot; the comparative behavior of *Diplodia* and *Phomopsis*, C. BROOKS. (U. S. D. A.). (*Fla. State Hort. Soc. Proc.*, 54 (1941), pp. 61-63).—Studying stem-end rot, from the standpoints of both grower and consumer one of the most serious diseases of Florida citrus fruits and caused by either *D. natalensis* or *P. citri*, numerous inoculations indicated that the former at 75° F. works about twice as fast as the latter. However, culture tests showed that in commercial operations *Phomopsis* is the

more important cause of decay in oranges that have not passed through the coloring room, whereas *Diplodia* causes nearly all that on fruit receiving the ethylene treatment. The reason was found to be that ethylene gas stimulates the thick-walled *Diplodia* spores to germination. Borax is generally recognized as the best fungicide for controlling stem-end rot, but tests showed that it must be applied previous to the coloring room treatment to be fully effective. Other fungicides used, such as Na phenyl-phenate, have given promise but need further trials.

A Laschia on cabbage palmetto, V. K. CHARLES (U. S. D. A.). (*Mycologia*, 34 (1942), No. 3, pp. 235-240, fig. 1).—*L. sabalensis* n. sp. is described from dead leaves of *Sabal palmetto*.

Observations on the life history of Anguillulina pratensis, C. H. GADD and C. A. LOOS (Ann. Appl. Biol., 28 (1941), No. 1, pp. 39-51, figs. 4).—Measurements of this nematode collected from tea cortex and soils are summarized. Attempts to maintain it in vitro were unsuccessful. A rapid method for determining the nematode content of roots is described, and its value in studying the life cycle of this form is demonstrated. The females average 1.6 eggs per day for a period rarely exceeding 5 weeks. The eggs hatch in 15-17 days, the adult stage is reached in 15-16 days, and the females begin to lay about 15 days later. In the absence of males, egg-laying is usually delayed.

Science and roses, L. M. MASSEY. (Cornell Univ.) (Amer. Rose Ann., 1942, pp. 61-67).—A brief review of past research on roses and on their diseases and pests, initiated on the appearance of the new American Rose Annual Cumulative Index.

Continued rose research at Cornell, R. C. ALLEN. (Cornell Univ.) (Amer. Rose Ann., 1942, pp. 99-101).—This is a progress report on studies having particular reference to winter injury of roses, its causes and protection against it.

White pine blister rust control—Michigan.—Annual Report, 1941, J. K. KROEBER ([Lansing]: Mich. Dept. Agr. 1941, pp. [6]+34, figs. 2).—See previous reports (E. S. R., 85, p. 498).

Decay of western hemlock in western Oregon and Washington, G. H. ENGLEBETH. (U. S. D. A.). (Yale Univ. School Forestry Bul. 50 (1942), pp. [4]+53, pls. 6, figs. 3).—Western hemlock (*Tsuga heterophylla*) is said to be one of the most important forest trees in the Pacific Northwest, where it attains its maximum development. In cruising and marking for cutting, forest officers often encounter decays which are not typical of the brown stringy rot due to *Echinodontium tinctorium*, which has generally been considered ubiquitous on this species. Because of this observation the present study was initiated and carried out (1935-40), involving the dissection and analysis of 801 trees for decay. *Fomes annosus* root rot was found responsible for 21 percent of the board-foot volume decayed, *F. pini* conk rot for 19.2, *F. applanatus* white mottled rot for 17.1, *F. hartigii* white trunk rot for 10.1, *Ganoderma oregonense* white spongy rot for 7.2, *F. pinicola* brown crumbly rot for 6.7, *E. tinctorium* brown stringy rot for 5.3, *Poria colorea* n. sp. spongy butt rot for 4.3, *Armillaria mellea* shoestring-fungus rot for 3.7, *Polyporus sulphureus* brown cubical rot for 2.3, *P. officinalis* brown trunk rot for 1.5, *P. schweinitzii* red-brown butt rot for 0.9, and *Polystiotes abietinus* pitted sap rot, *F. subroseus* yellow-brown top rot, and *Poria subacida* feather rot each for 0.1 percent.

The various infection courts for decay in this tree were knots, falling-tree scars, roots, mistletoe burls and knots, broken tops, fire scars, lightning scars, and frost cracks. Though more infections occurred through falling-tree scars than otherwise, those through mistletoe knots accounted for the greatest amount of decay. Ordinary knots ranked third in number of infections and second in

percentage of total decay. Infection through mistletoe burls and swollen limbs adjacent to the trunk accounted for 30.9 percent of the decay volume in board-feet. In general, western hemlocks were frequently infected at 60–85 yr. of age, and decay became extensive at about 200 yr. Conk rot and white trunk rot were most frequent on the Cascade areas, but *Fomes* root and white mottled rots were more common on the coast areas. Brown stringy rot was limited to trees of poor vigor at high elevations and on poor sites, and the injury from this cause was negligible in the commercial stands in western Oregon and Washington. There are 40 references.

Effect of addition of sugar on rate of decay of wood, W. P. K. FINDLAY (*Ann. Appl. Biol.*, 28 (1941), No. 1, pp. 19–22).—No significant difference was found in the amount of decay of beech and pine by various fungi between samples of wood treated with 0.5–1 percent solutions of sucrose or with 1 percent dextrose, and controls treated with water. The loss in weight of samples treated with 5 percent sucrose or 2.5 percent dextrose was less than that of the controls, but with allowance for the full weight of the sugar added the total loss was slightly greater than that of the controls. It is believed that a large proportion of such loss is due to destruction of the sugar and that the destruction of wood substance is less in the presence of large amounts of readily available sugars, which are utilized by the fungus in preference to the more refractory polysaccharides in the wood.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Catalog of the type specimens of mammals in the United States National Museum, including the Biological Surveys collection, A. J. POOLE and V. S. SOHANTZ (*U. S. Natl. Mus. Bul.* 178 (1942), pp. XIII+705).—Included in this second catalog (*E. S. R.*, 20, p. 1144) are a geographical guide to type localities (pp. 577–640), a list of collectors of the type specimens of mammals in the United States National Museum, including the Biological Survey's collection (pp. 641–646), and an index to generic, specific, and subspecific names (pp. 647–705).

On the analysis of productivity in populations of higher vertebrates, P. L. EBRINGTON. (Iowa Expt. Sta. et al.). (*Jour. Wildlife Mangt.*, 6 (1942), No. 2, pp. 165–181).

Insect feeding by the house mouse [*Mus musculus*], J. P. LINDUSKA (*Jour. Mammal.*, 23 (1942), No. 2, pp. 212–213).

Ecology of the opossum [*Didelphis virginiana*] in eastern Texas, D. W. LAY (*Jour. Mammal.*, 23 (1942), No. 2, pp. 147–159, figs. 3).

Cottontail rabbit nests and nestlings, J. D. BEULE and A. T. STUDHOLME. (Pa. Expt. Sta. et al.). (*Jour. Wildlife Mangt.*, 6 (1942), No. 2, pp. 133–140, pl. 1).

Using baits in rat control, E. M. MILLS (*Pests*, 10 (1942), No. 5, pp. 6–7, 28).

The fortification of red squill [*Urginea maritima*] by means of an extract of red squill, D. G. CRABTREE, J. C. WARD, and F. E. GARLOUGH (*Jour. Amer. Pharm. Assoc.*, 31 (1942), No. 5, pp. 142–144, figs. 2).—Account is given of an efficient method that has been developed for the fortification of red squill powder, using the counter-current principle of extraction. In this way it is possible to increase the potency of weak red squill powder to the point where it can be used efficiently in rat-control operations. Fortified red squill contains all of the safety factors inherent in red squill powder, and the solvent is recovered and used again in the process. This method may easily be adapted to large or small scale operations.

An ecological study of winter dens, with special reference to the eastern skunk, D. L. ALLEN and W. W. SHAPTON (*Ecology*, 23 (1942), No. 1, pp. 59-68, figs. 3).

Some major factors affecting the use of two inventory methods applicable to the western fox squirrel (*Sciurus niger rufiventer* (Geoffroy)), E. A. HICKS. (Iowa Expt. Sta. et al.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 2, pp. 299-305).

A note on squirrel damage to conifers, R. E. BALCH (*Forestry Chron.*, 18 (1942), No. 1, p. 42).—A brief reference is made to the damage of conifers caused by the red squirrel cutting off shoot buds from late summer to spring. The squirrel supplements its winter diet of hoarded material with buds of various trees, the balsam and fir flower buds being preferred in the Maritime Provinces of Canada.

Proc.*, 83 (1942), pp. 59-61, 70-97, figs. 3).—Among the contributions presented at Harrisburg in January 1942 are the following: Peach Borer Control Tests (pp. 59-61) and Studies of Codling Moth Cover Sprays in 1941 (pp. 80-92), both by H. N. Worthley, and Dormant Sprays on Peach (pp. 74-79) and Apple Sprays—Dormant Through Petal-Fall (pp. 93-97), both by H. M. Steiner (all Pa. Expt. Sta.); and Report of Gypsy Moth in Pennsylvania in 1941, by T. L. Guyton (pp. 70-72).

Methods of insect control, I, II, D. ISELY (*Minneapolis, Minn.: Burgess Pub. Co.*, [1941], pt. 1, 2. ed., rev., pp. [1]+II+121; [1942], pt. 2, 3. ed., rev., pp. [1]+II+135).—These parts are presented in 19 and 18 chapters, respectively, each part including a list of references to the literature. An index to species and insecticides is given in part 2.

Some pertinent facts and some important theories about contact insecticides, W. C. O'KANE (*Pests*, 10 (1942), No. 3, pp. 16-19).

Fumigating action of a mixture of orthodichlorobenzene and naphthalene applied by a new method, W. N. SULLIVAN, E. R. MCGOVAN, and L. D. GOODRUE (U. S. D. A.). (*Pests*, 10 (1942), No. 4, pp. 16-17).

Caution urged in use of kerosene-rotenone spray, W. EBELING. (Calif. Citrus Expt. Sta.). (*Citrus Leaves*, 22 (1942), No. 4, pp. 1-2).

Grasshopper problems associated with strip cropping in western Kansas, D. A. WILBUR, R. F. FRITZ, and R. H. PAINTER. (Kans. Expt. Sta.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 1, pp. 16-29, figs. 5).—Report is made of an investigation conducted in Greeley County, Kans., in the dry-farming district, where a large area is devoted to strip cropping in order to prevent wind erosion. The widespread injury to fall wheat by *Melanoplus mexicanus* Sauss. at wheat-seeding time led to the conducting of this experiment with many variations, each with numerous replications. The details are presented in tables and graphs.

In Greeley County this grasshopper frequently has a partial or complete second generation, which in 1940 coincided with the germination of fall wheat. "The extent of the field margins of strip-cropped wheat as compared to solid-planted wheat greatly influenced the amount of feeding injury by *M. mexicanus* as well as the amount of bait required to check the infestation. Strips of fall wheat bordered by small grain stubble suffered much more extensive injury than when bordered by sorghums even though considerable populations of the grasshopper were present in the sorghums, indicating that even a partial replacement of wheat or barley by sorghums tends to alleviate the *M. mexicanus* problem. Weedy pastures, abandoned fields, and roadsides carried populations of [*M.*] *mexicanus* similar to those in the stubble, and the injury to adjoining wheatfields was comparable to that of fields adjoining stubble. Improving the condition of the pastures and eliminating the roadside strips are desirable measures for combating the grasshopper problem. Thirty times more bait was used during August and September than was used in May through July. Distributing grasshopper baits before seeding wheat resulted in a marked reduction in the extent of injury to the wheat as compared to baiting only after seeding."

Migrations and food preferences of the lubberly locust, J. R. WATSON (*Fla. Ent.*, 24 (1941), No. 2, pp. 40-42).

A single treatment for gladiolus corms to destroy all stages of the gladiolus thrips, J. B. STEINWEDEN, D. B. MACKIE, W. B. CARTER, and S. S. SMITH (*Calif. Dept. Agr. Bul.*, 31 (1942), No. 1, pp. 31-39, figs. 2).—The results of work conducted in which gladiolus corms were fumigated with methyl bromide at various schedules for the control of the gladiolus thrips and also to check the effect of this fumigant on the germination and blossom yields are reported. It is concluded that the recommended treatments should be 2 lb. per 1,000 cu. ft. for 3 hr. at 80° F. or 3 lb. for 2 hr. at 80°. Longer treatments are cautioned against to avoid injury to corms, while shorter treatments will probably reduce the kill of the thrips. The temperature of the corms and the fumigation chamber should reach 80° before the gas is injected, and this temperature should be maintained during the exposure period. Long periods of heating might reduce the relative humidity of the chamber to the point where corm injury might occur, so the relative humidity should be 60 percent or above. Treated corms should be protected from reinfestation.

Effect of certain weather conditions on chinch bug abundance at the Dry Land Field Station of the United States Department of Agriculture at Lawton, Okla., 1916-40, R. G. DAHMS and W. M. OSBORN. (U. S. D. A. and Okla. A. and M. Col.). (*Ecology*, 23 (1942), No. 1, pp. 103-106).

The daily flight of aster leafhoppers as determined by a light trap, J. G. LEACH and J. R. MULLIN. (W. Va. Expt. Sta.). (W. Va. Univ. Bul., 42. ser., No. 8-II (1942), pp. 93-95, figs. 2).

A description of *Aphis (Doralis) rumicis* L. and comparison with *Aphis (Doralis) fabae* Scop., M. G. JONES (*Bul. Ent. Res.*, 33 (1942), No. 1, pp. 5-20, figs. 7).—A review of the early literature on the occurrence of black aphids on dock has shown that confusion has arisen between two distinct species, the polyphagous bean-spindle aphid and the monophagous dock aphid. A discussion on the nomenclature of the two species follows, and the names *A. (Doralis) fabae* and *A. (Doralis) rumicis*, used on the European continent, are adopted. The different generations are described and figured. A comparison of *D. rumicis* and *D. fabae* shows that both colonies and single individuals can be distinguished easily from one another. The results of host transference experiments shows that *D. rumicis* only colonizes plants belonging to the genus *Rumex*, and the alatae viviparae show some slight response to the odor of dock. There is no gynopara as in *D. fabae*, and the sexupara gives rise to apterae viviparae, males, and oviparae.

Some grass aphid host records (Homoptera), G. F. KNOWLTON and W. D. FRONK. (Utah Expt. Sta.). (*Ent. News*, 53 (1942), No. 4, pp. 112-114, fig. 1).—This contribution includes a number of host records for aphids taken on grass in Utah, not given in the Patch Food-Plant Catalogue of the Aphids of the World (E. S. R., 81, p. 679). A new species found on grass at Lincoln in Tooele County is described under the name *Amphorophora allent*.

Mortality of the red scale on citrus through infection with a spore-forming bacterium, V. P. SOKOLOFF and L. J. KLORZ. (Calif. Citrus Expt. Sta.). (*Phytopathology*, 32 (1942), No. 3, pp. 187-198, figs. 3).—Adult females of California red scale can be infected and destroyed under laboratory conditions by a spore-forming facultatively anaerobic nitrate-reducing mesophilic bacterium, recently isolated from the soil, that is tentatively designated as *Bacillus* "C." The infected insects commonly contain bubbles of gas. Distortion of pygidia and browning of the ventral surface precede disintegration and drying of the dead individuals. A few days after the infection it may be observed growing in long chains on the waxy margin of the insect and, as vegetative cells and spores, in the contents of the general cavity. Expulsion of dead crawlers often occurs

in the early stages of the invasion. The pathogenicity of the micro-organism is lost after a period of growth on synthetic media but is restored upon its reisolation from sterile soil. The loss of pathogenicity is accompanied by a significant failure to grow anaerobically in the presence of nitrate. The lethal effect of the micro-organism is possibly associated with reduction of nitrate contained in the insects.

[California] red scale out-of-doors in Berkeley, California, E. O. ESSIG (*Pan-Pacific Ent.*, 18 (1942), No. 2, p. 82).

Kerosene-rotenone spray: Some of the problems attending its use as a control for red scale, W. ERELING. (Calif. Citrus Expt. Sta.). (*Calif. Citroy.*, 27 (1942), No. 7, p. 188).

Some problems of control of scale insects on citrus, W. L. THOMPSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 23 (1942), No. 6, pp. 6-7, 14-15, 18-19).

Coleoptera associated with ironweed (Vernonia interior Small) in Kansas, R. B. SCHWITZGEBEL and D. A. WILBUR. (Kans. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 15 (1942), No. 2, pp. 37-44, figs. 5).—In the study reported at least 47 species comprising 14 families of Coleoptera were found in Kansas associated with *V. interior*, directly by feeding on the plant or indirectly as visitors.

A checklist of the Cicadellidae at Chatham, Virginia, with thirteen new records for the State, G. WENE and C. B. DOMINICK. (Va. Expt. Sta.). (*Va. Jour. Sci.*, 2 (1941), No. 5, pp. 122-123).

A new species of Hippodamia from Mexico (Coleoptera: Coccinellidae), P. H. TIMBERLAKE. (Calif. Citrus Expt. Sta.). (*Ent. Soc. Wash. Proc.*, 44 (1942), No. 3, p. 39).—Under the name *H. koebelii* description is given of a new ladybird beetle collected at several points in Mexico.

Biology of Calopepla leayana Latr. (Chrysomelidae: Col[eo]ptera) and the possibilities of control, P. F. GARTHWAITE (*Indian Forest Rec., n. ser., Ent.*, 5 (1938), No. 2, pp. IV+237-277, pls. 2).—A report is made on the synonymy and biology of the chrysomelid beetle *C. leayana*, which defoliates *Gmelina arborea*, a tree that has been planted in Burma on an extensive scale to supply pitwood for use in mines.

Descriptions and records of distribution of Phyllophaga (Coleoptera: Scarabaeidae), M. W. SANDERSON. (Ark. Expt. Sta.). (*Jour. Kans. Ent. Soc.*, 15 (1942), No. 2, pp. 49-55, pl. 1).—*P. sylvatica*, from Arkansas and other Middle West and Southeastern States, and *P. inopia*, from Arizona and Mexico, are described as new. Five additional species from the United States, of which four are recorded for the first time, are discussed.

The tribe Monochamini in the Western Hemisphere (Coleoptera: Cerambycidae), I. S. and E. S. DILLON (*Reading Pub. Mus. and Art Gallery, Sci. Pubs.*, No. 1 (1941), pp. [1]+135, pls. 5).—This monograph includes descriptions of many new species.

Bionomics of the meloid genus Hornia (Coleoptera), E. G. LINSLEY and J. W. MACSWAIN (*Calif. Univ. Pubs. Ent.*, 7 (1942), No. 9, pp. [2]+189-205, pls. 2, fig. 1).

Carpet beetles, C. J. WEINMAN. (Ill. Expt. Sta. and Ill. Nat. Hist. Survey). (*Pests*, 10 (1942), No. 4, pp. 6-8, 30-31).

The white pine weevil and its control by the application of concentrated sprays, S. F. PORTS, A. C. CLINE, and H. L. MCINTYRE. (U. S. D. A. et al.). (*Jour. Forestry*, 40 (1942), No. 5, pp. 405-410, figs. 4).—Details are given of the treatment of the white-pine weevil, which can be controlled effectively through the application of a poison spray that kills the female before the eggs are laid.

The biology and behaviour of Ptinus tectus Boie. (Coleoptera: Ptinidae), a pest of stored products, II, III (*Jour. Expt. Biol.*, 18 (1942), No. 3, pp.

278-305, *figs. 10*.—The second part of this contribution (E. S. R., 87, p. 95) relates to the amount of locomotory activity in relation to experimental and to previous temperatures, by D. L. Gunn and H. S. Hopf (pp. 278-289). The third part deals with the effect of temperature and humidity on oviposition, feeding, and duration of life cycle, by D. W. and R. F. Ewer (pp. 290-305).

Scolytus sulcatus and apple trees in relation to the Dutch elm disease control program, S. J. SMUCKER (U. S. D. A.). (*Phytopathology*, 32 (1942), No. 5, pp. 441-442, *fig. 1*).—It is concluded that even though *Ceratostomella ulmi*, the causative fungus of Dutch elm disease, is capable of remaining viable for considerable periods of time in living apple trees and also in apple wood, the probability of the bark beetle *S. sulcatus* transmitting it to apple wood in nature and of the apple wood being an important source of inoculum for later spread is relatively unimportant at present in the Dutch elm disease control program.

Height of corn as a factor in egg laying by the European corn borer moth in the one-generation area, L. H. PATCH. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 9, pp. 503-515, *figs. 3*).—More egg masses of the European corn borer were laid in fields of tall corn within an area than in fields of short corn, but the difference was less marked in areas where the general level of corn height was high. Where corn within a unit area averaged 32.4 in. in height, 8.3 times as many egg masses were laid in the fields of tallest corn as in fields of shortest corn; where corn in unit areas averaged 60.4 in. at the time of moth flight, only 1.7 times as many egg masses were counted in the fields of tallest corn. About twice as many egg masses were found in counties with corn above average in height as in counties with below-average corn, when data were grouped on a county basis without regard to unit areas within them. Apparently this did not result from higher levels of early summer infestations of egg masses in areas of tall corn preceded by higher levels of fall populations of borers. Moths were attracted as much more to fields of tall corn than to fields of short corn as they were to plats of tall corn than to plats of short corn within experimental fields.

Strains of field corn resistant to the survival of the European corn borer, L. H. PATCH, J. R. HOLBERT, and R. T. EVERLY (U. S. Dept. Agr., *Tech. Bul.* 823 (1942), pp. 22).—Open-pollinated varieties, inbreds, and hybrid strains of field corn were tested for their resistance to the survival of the European corn borer by infesting the plants with eggs produced in the laboratory. After allowing for the differences in maturity of the strains as measured by silking date, relatively low levels of mature borers were obtained during a 10-yr. period from resistant strains and high levels from susceptible strains. Partially resistant strains had intermediate borer levels. Open-pollinated varieties averaged 25 percent more than the predicted mean numbers of borers in strains silking on the same dates. Inbreds Ill. R4, Ia. L317, Wis. OC5, Mich. 77, and Mich. 106 averaged 32 percent less than the predicted numbers of borers; inbreds Ill. Hy, Ind. TR, U. S. 540, Ia. I205, Wis. CC1, Ill. A48, and Ill. L averaged 8 percent less than the predicted number of borers; and inbreds Ill. A, Ill. 90, Ind. WF9, and U. S. 187-2 averaged 33 percent more than the predicted number of borers. Single-cross hybrids involving two resistant inbreds averaged 39 percent less than the predicted numbers of borers. Hybrids involving two susceptible inbreds averaged 58 percent more than the predicted numbers of borers. Hybrids involving different combinations of resistant, partially resistant, and susceptible inbreds and hybrids involving two partially resistant inbreds contained populations of borers between these two extremes. The cumulative effect of an undetermined number of multiple factors in inbred lines in producing borer resistance in hybrids is indicated. A comparison of sister inbred lines, sepa-

rated at the second to the fifth generation of inbreeding, showed that the difference between sisters of pairs of sisters in transmitting borer resistance to hybrids averaged not much larger than the difference found between the members of pairs of samples of the same strains, indicating little advantage in testing sister strains.

Later planting reduces corn borer damage, L. L. HUBER (*Ohio Sta. Bmo. Bul.* 215 (1942), pp. 72-73, fig. 1).—A practical account which discusses the advantages of late planting of corn to reduce damage by the European corn borer.

The codling moth menace, W. D. WHITCOMB. (Mass. Expt. Sta.). (*Mass. Fruit Growers' Assoc. Rpt.*, 48 (1942), pp. 27-35).

The subterranean grass caterpillar, *Oxycanus* sp., chemical control investigations, 1940 season, L. J. DUMBLETON and R. D. DICK (*New Zeal. Jour. Sci. and Technol.*, 22 (1941), No. 6A, pp. 309A-322A, fig. 1).—In experimental control work with the subterranean grass caterpillar, a poison bait consisting of 1 lb. of paris green, 25 lb. of bran, 8 lb. of molasses, and 3 gal. of water gave a 77-percent reduction in larval population when applied at the rate of 60 lb. of wet bait per acre and a 63-percent reduction when applied at the rate of 120 lb. per acre to infested ground bare of grass. The same bait applied at the rate of 120 lb. per acre gave an 87-percent reduction in population when applied to infested plats on which grass was present.

Notes on the larvae of the three common injurious species of *Ephestia* (Lepidoptera: Phycitidae), H. E. HINTON (*Bul. Ent. Res.*, 33 (1942), No. 1, pp. 21-25, pl. 1, figs. 15).—Descriptive keys are given to the mature or nearly mature and the first-stage larvae of the Indian-meal moth, tobacco moth, Mediterranean flour moth, and the almond moth.

The "orange moth" of Dominica, B. W. I., R. G. FENNAH (*Trop. Agr. [Trinidad]*, 19 (1942), No. 4, pp. 73-78, figs. 2).—The orange moth, thought to be a new species of the genus *Gymnandrosoma* (family Olethreutidae) and here reported upon, causes a small seasonal loss of fruit from time to time in upland parts of Dominica. The larvae bore into the developing fruit, affording entry for various fungi.

Some observations on the life history of the Angleshades moth *Brotolomia meticulosa* L., W. J. PARR and E. R. SPEYER (*Ann. Appl. Biol.*, 28 (1941), No. 1, pp. 29-33, pl. 1).—Report is made of observations of *B. meticulosa*, a moth which is common and widely distributed in Europe and often inhabits glasshouses, especially those devoted to cultivation of chrysanthemums. The caterpillars are very destructive to chrysanthemum flowers and at least in the later instars prefer petals to foliage, although they have been reared with ease entirely upon the latter. They feed voraciously upon leaves of cineraria and geranium and caused much injury to those of broad beans grown under glass during the winter of 1939-40.

New Jersey mechanical trap for mosquito surveys, T. D. MULHERN (*New Jersey Stas. Cir.* 421 (1942), pp. 8, figs. 3).—A practical account, including a description of a mechanical trap, selection of proper location for operation, method of operation, suggestions for trap service, and interpretation of results.

Mosquitoes of the Ethiopian region.—III, Culicine adults and pupae, F. W. EDWARDS (*London: Brit. Mus. (Nat. Hist.)*, 1941, vol. 3, pp. VIII+499, pls. 4, figs. 184).—The third volume of this work (*Il. S. R.*, 81, p. 548) deals with the adults and pupae of culicine mosquitoes under headings of taxonomy of adults (pp. 6-353) and of pupae (pp. 354-428), includes corrigenda and addenda (pp. 429-447), and discusses the zoogeography of Ethiopian mosquitoes (pp. 448-485). A six-page list of references to the literature is included.

The fever fly *Dilophus febrilis* L. and methods for control of its larvae in cultivated lawns, E. E. EDWARDS (*Ann. Appl. Biol.*, 28 (1941), No. 1, pp. 34-38).—The symptoms of attack by larvae of *D. febrilis* in lawns under conditions of continual mowing and a brief description of its life history are presented. Report is made of control experiments conducted in 1939 with calomel, orthodichlorobenzene, lead arsenate, and derris preparations applied against larvae in cultivated lawns. Lead arsenate at 1.5 oz. per square yard and also a derris-pyrethrum mixture (0.0054 percent rotenone and 0.001 percent pyrethrin I) used at 1 gal. per square yard gave almost complete control. A liquid derris preparation alone (0.0054 percent rotenone) gave on the average about 95-percent control and an emulsion containing 1 percent orthodichlorobenzene about 72 percent control, both applied at 1 gal. per square yard. A 4-percent calomel dust at $\frac{3}{8}$ oz. per square yard was ineffective.

Sampling for leatherjackets with orthodichlorobenzene emulsion, H. F. BARNES (*Ann. Appl. Biol.*, 28 (1941), No. 1, pp. 23-28, figs. 2).—The orthodichlorobenzene method has been found satisfactory for estimating rapidly the numbers of leatherjackets (tipulid larvae) present early in the year, providing it is used on suitable days, i. e., damp rather than dry ones and warm rather than frosty ones. About 80 percent of the leatherjacket population is then obtained. Later in the season when the leatherjackets are approaching their fully fed stage, the method is unreliable. For one reason the leatherjackets appear to become immune to orthodichlorobenzene and, secondly, at this period a definite movement away from the original feeding site appears to take place. The dates when the treatment becomes ineffective vary from year to year, but generally speaking it is effective till the end of March, although it may be used some years throughout April with good results.

The crane flies (Tipulidae) of the George Reserve, Michigan, J. S. ROGERS (*Mich. Univ., Mus. Zool. Misc. Pub.* 53 (1942), pp. 128, pls. 8, fig. 1).—Following the introduction, the seasonal distribution (pp. 18-30), habitat distribution (pp. 30-55), relationships of the crane fly fauna with the other members of the biota (pp. 55-57), an annotated list (pp. 58-118), and additional notes for the spring of 1941 (pp. 118-127) are presented.

Notes on *Theresia claripalpis* Wulp (Diptera: Tachinidae), a parasite of *Diatraea* spp. in Trinidad, B. W. I., E. M. CALLAN (*Trop. Agr. [Trinidad]*, 19 (1942), No. 4, pp. 71-73).—A total of 4,232 *Diatraea* larvae were found in 18,497 sugarcane "dead hearts" cut in the field on an estate (Caroni) in Trinidad in 1941. "*D. impersonatella* Wlk. was the most abundant moth borer; 69.2 percent of the moth borers were this species, 29.8 percent *D. canella* Hmps., and 1.0 percent *D. saccharalis* F. *T. claripalpis* was the only tachinid parasite found. Neither *Stomatoderia diadema* Wied. nor the Amazon fly *Metagonistylum minense* Tns. were obtained. It is suggested that the Amazon fly (introduced into Trinidad in 1936 and 1937) has not become established at Caroni Estate. A total of 399 puparia of *T. claripalpis* were obtained; 231 were 'field collected' and 168 'lab reared.' *T. claripalpis* showed a distinct host preference for both *D. saccharalis* and *D. impersonatella*; 8.9 percent of *D. saccharalis* were parasitized, 5.4 percent of *D. impersonatella*, and 0.4 percent of *D. canella*." A successful method of shipment of live puparia of *T. claripalpis* from Trinidad to Canada is described.

A new species of Oedematocera, with notes and key (Tachinidae: Diptera), H. J. REINHARD. (Tex. Expt. Sta.). (*Ent. News*, 53 (1942), No. 4, pp. 106-108).—A key is given for the identification of the species of *Oedematocera* and a description of *O. optata* n. sp. taken at Cold Spring Harbor, N. Y.

Notes on Fabriciella, with descriptions of five new species (Tachinidae: Diptera), H. J. REINHARD. (Tex. Expt. Sta.). (*Bul. Brooklyn Ent. Soc.*, 37 (1942), No. 1, pp. 24-30).

The parasitic fly *Zelia vertebrata* Say (Diptera: Dexiidae), J. F. MANGRUM (*Ann. Ent. Soc. Amer.*, 35 (1942), No. 1, pp. 73-75, figs. 9).—A brief account is given of observations of the dexiid fly *Z. vertebrata*, found to parasitize the large larvae and pupae of the horned passalus.

***Sarcophaga bullata* Parker as a cause of intestinal myiasis,** J. R. WATSON (*Fla. Ent.*, 25 (1942), No. 1, pp. 5-6).

The apple maggot problem again: Recent observations and trapping experiments, D. M. BENJAMIN and A. C. HODSON. (Minn. Expt. Sta.). (*Minn. Hort.*, 70 (1942), No. 3, pp. 54-55).

The house fly as a vector of food poisoning organisms in food-producing establishments, M. OSTBOLENK and H. WELCH (*Amer. Jour. Pub. Health*, 32 (1942), No. 5, pp. 487-494, figs. 2).—Experimental work has shown that flies fed on food infected with *Salmonella enteritidis* are capable of infecting other flies as well as the food, water, and miscellaneous surfaces with which they come into contact. *S. enteritidis* apparently survives in the fly for the duration of the life of the fly, approximately 4 weeks. Transfer of *S. enteritidis* infection from infected flies to mice and the retransfer of infection from infected mice to flies was successfully carried out. Fly eggs planted in mash infected with *S. enteritidis* resulted in infected maggots, pupae, and adults.

Housefly control in relation to poliomyelitis, G. E. SANDERS (*Pests*, 10 (1942), No. 3, pp. 22-26).

Poliomyelitis virus from flies, J. A. TOOMEY, W. S. TAKACS, and L. A. TISCHER (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 3, pp. 637-639).—The isolation of poliomyelitis virus from flies exposed to natural sources of infection is reported.

Index to the literature of Siphonaptera of North America, W. L. JELLISON and N. E. GOOP (*U. S. Pub. Health Serv., Natl. Inst. Health Bul.* 178 (1942), pp. IV+193).—This systematically arranged catalog index to the fleas of North America includes hosts and localities of collection, a guide to type localities, a bibliography of 18 pages, and an index.

Poisoning of the honeybee, C. G. BUTLER (*Bee World*, 23 (1942), No. 5, pp. 38-39).—A contribution from the Rothamsted Experimental Station.

Further observations on the resistance of bees to American foulbrood, J. E. ECKERT. (Univ. Calif.). (*Amer. Bee Jour.*, 82 (1942), No. 6, pp. 261-262).—A further report of bee resistance to American foulbrood (*E. S. R.*, 86, p. 364).

Argentine ant in Hawaii, E. C. ZIMMERMAN (*Hawaii. Ent. Soc. Proc.*, 11 (1941), No. 1, p. 108).—This note records the discovery of the Argentine ant in the Hawaiian Islands for the first time, it being well established at Fort Shafter in Honolulu.

Tick parasites on Cape Cod, S. COBB (*Science*, 95 (1942), No. 2472, p. 503).—Attempts made in July and August 1940 to parasitize the American dog tick with *Hunterellus hookeri* How. failed, although five adults were collected in the hair of a Setter dog. One larva of this tick yielded two specimens of *Ixodiphagus texanus* How. This is believed to be the first report of this chalcid as a parasite of the American dog tick, although there are a number of records from Oak Bluffs, Mass., of its parasitism of the rabbit tick and of *Ixodes dentatus*.

The sex-ratio in the Hymenoptera: A function of the environment, S. E. FLANDERS. (Calif. Citrus Expt. Sta.). (*Ecology*, 23 (1942), No. 1, pp. 120-121).

A check list of the parasitic Hymenoptera of the Samoan Islands, with descriptions of new species appended, D. T. FULLAWAY (*Hawaii. Ent. Soc. Proc.*, 11 (1941), No. 1, pp. 41-49).

Rust mites on citrus, J. R. WATSON. (Fla. Expt. Sta.). (*Citrus Indus.*, 23 (1942), No. 5, pp. 3, 14).

Primera contribución al estudio de la bionomía del *Argas persicus* [A contribution on the biology of the fowl tick], R. J. ROVEDA (*Buenos Aires Univ., Inst. Parasitol. y Enferm. Parasit.* [Pub.], 1 (1940), No. 6, pp. 22).

Notes on the life cycle of *Capillaria annulata*, P. J. ZUCCHERO (*W. Va. Univ. Bul.*, 42. ser., No. 8-II (1942), pp. 96-106).

ANIMAL PRODUCTION

[Investigations dealing with livestock production by the Illinois Station] (*Illinois Sta. Rpt.* 1938, pp. 79-86, 95-105, 108-110, 130-136, figs. 2).—H. P. Rusk, R. R. Snapp, S. Bull, R. J. Webb, T. S. Hamilton, W. Burroughs, B. W. Fairbanks, W. E. Carroll, W. G. Kammlade, G. A. Branaman, E. Roberts, J. H. Longwell, and F. Simpson report on progress made on investigations of the effect of cane molasses as a substitute for all or part of the corn in the ration of yearling steers on gain, grade, and quality of meat produced; rye for winter pasture of sows; protein needs of growing-fattening pigs; sows with pigs thrive on rye pasture, with shelled corn and protein supplement; fermenting farm grains with yeast for swine; fattening values of rations fed to lambs on different kinds of pasture; rats show preference for inbred and hybrid corn; and the effect of oat flour as a preservative for fat in pork products.

[Experiments in animal production by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 414 (1941), pp. 26-27, 29, 40-43, figs. 2).—Results are briefly reported by W. L. Henning, E. B. Forbes, R. W. Swift, R. V. Boucher, P. H. Margolf, and R. R. Murphy on comparisons of three and four breed crosses in sheep for early lamb production; the base value of heat production of animals; the use of molasses to replace corn in poultry rations; the need by turkey hens of riboflavin if fertile eggs are to be produced; vitamin D requirements of growing turkeys; and the reduction of feed costs of turkeys on range by the use of whole oats.

[Investigations in animal production by the South Dakota Station] (*South Dakota Sta. Rpt.* 1941, pp. 13-18, 19-22, 40-46, 46-47, figs. 2).—Results are briefly reported by T. Wright, F. U. Fenn, I. B. Johnson, J. C. Watson, J. W. Wilson, W. E. Poley, W. O. Wilson, A. L. Moxon, H. D. Anderson, J. B. Taylor, and R. L. Dolecek on a comparison of several protein supplements for pigs after weaning; quality of pork produced on pasture; comparison of ground and whole Sooner milo with corn for fattening fall pigs; baby beeves economically produced; comparison of rations containing corn, cane, and millet for fattening steers; comparative rations for pregnant ewes; progress with the notall breed of sheep (E. S. R., 83, p. 756); carrying capacity of South Dakota ranges and pastures; beet tops and beet pulp for lambs; sorghums and proso millet for turkeys; effect of rations on fertility and hatchability of turkey eggs; use of supplements, particularly linseed meal, to selenium rations for the laying hen; relation of egg quality and poultry meat to grain varieties; and different percentages of protein for egg production.

[Experiments by the Wisconsin Station with cattle, swine, and poultry] (*Wisconsin Sta. Bul.* 455 (1942), pp. 1-5, 8-18, figs. 7).—Results are briefly presented by W. H. Peterson, G. P. Bahler, R. P. Niedermeler, G. Bohstedt, I. W. Appel, F. W. Duffee, B. Ross, J. Fargo, W. C. Weir, P. Phillips, J. C. Halpin,

W. W. Cravens, C. E. Holmes, and H. Lardy, concerning the preservation of grass silage; liberal alfalfa in rations for pigs gives high returns; sunshine and minerals for pigs; excess magnesium harmless for pigs; poultry rations; distillers' waste not good protein supplement for poultry; salt and protein feeds prevent cannibalism in poultry; sunlight helps prevent slipped tendon or perosis in growing chicks; and artificial insemination in poultry.

The evaluation of feeds on the basis of digestible and metabolizable nutrients, H. H. MITCHELL. (Univ. Ill.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 159-173).—A discussion by the Committee on the Evaluation of Feeds of the American Society of Animal Production points out the various factors that should be considered in the conduct of metabolism, digestion, and energy experiments, with special reference to the chemical composition of feeds and their influence on digestibility.

Carotene and riboflavin in alfalfa, A. R. HANKE and A. T. PERKINS. (Kans. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 195-199, fig. 1).—An analysis by chemical methods of alfalfa meals collected in Kansas showed variations in the carotene content from 1.27 to 8.41 mg. per 100 gm. in 28 samples from sun-cured plants and 0.93-40.64 mg. per 100 gm. for 71 samples from dehydrated hay. In these products the ranges of riboflavin were 7.80 to 22.03 and 8.95 to 32.46 mg. per gram. In general, the dehydrated products were superior to the sun-cured products, and leaf meals were superior to the meals from the whole plant as sources of the carotene and riboflavin. Variations in the riboflavin were not as great as those for carotene.

The effect of manganese sulphate on the stability of vitamins A and D of cod liver oil when stored in mixed feeds, M. W. MILLER, V. JOUKOVSKY, and N. HOKENSTAD (*Poultry Sci.*, 21 (1942), No. 3, pp. 200-202).—Manganese sulfate acts as a drying agent on cod-liver oil. Assays showed it to cause the destruction of vitamins A and D when 0.5 percent of it and 9 percent of the oil was mixed with bran. There was no tendency to lose vitamin D in mixtures in which the manganese did not come in contact with the cod-liver oil. The vitamin D studies were made on mixtures stored up to 11 mo. at room temperature.

Correction of heat production for changes in live weight of cattle in balance experiments, R. W. SWIFT. (Pa. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 145-148).—Because of differences in the alimentary fill of cattle, suitable corrections and changes in live weight seem necessary in balance experiments. Carbon and nitrogen were shown to afford a more significant basis than live weight for judgment of gain or losses of body substances during periods of constant feed intake in successive trials with a steer. A correction for general use was computed as 432 kg. live weight and 7,181 Calories of heat production per day, which was the average of values for four steers on rations from fast to three times the maintenance, as computed by Forbes et al. (*E. S. R.*, 62, p. 656). The slight change in the correlation would result only in an increase of the slope of the curve for heat production in the previous publication.

Studies on large and small type Hereford cattle, R. R. WOODWARD, R. T. CLARK, and J. N. CUMMINGS (*Montana Sta. Bul.* 401 (1942), pp. 18).—A herd of grade Hereford cows was divided into small and large types and mated to bulls of these types for 9 yr. Study was made of the effect on cows, calves, yearlings, and 2-year-old heifers and steers of full feeding and limited rations which maintained weight during the winter on the heifer and steer calves. Those from the large type parents were generally larger at the different ages. Winter and summer gains of the large type were greater for both heifers and

steers in the full feed groups, but there was little difference in winter gains of helpers on the limited rations. Summer gains were mainly inversely proportional to winter gains. The birth weights of calves were found to be affected more by the type of their parents than by the ration fed. Steers from the large types were generally calculated as more profitable than steers from the smaller type sires and dams.

Growth and production factors in range cattle, B. KNAPP, JR., A. L. BAKER, J. R. QUESENBERRY, and R. T. CLARK. (Coop. U. S. D. A.). (*Montana Sta. Bul.* 400 (1942), pp. 13, figs. 3).—The average weights of 770 calves from 112 purebred Hereford cows raised at the U. S. Range Livestock Station from 1926 to 1940 are tabulated for birth and weaning weights at approximately 175 days of age and with reference to the dam's weight the previous fall. The average maximum production of range cows, judging from their weights and weights of their calves at birth and weaning, were reached at 4–8 yr. There were small changes in mature weight of the cows after 3.5 yr. of age. Analyses of variance showed that cows were responsible for 20 percent of the variation in the weaning weights of their calves. Other factors accounting for significant variations in the weaning weights of the calves were sires, age of weaning, and nutrition of the dam during the suckling period. Consideration should be given to the ability of the cow to reproduce rather than the condition of the cow in the selection for range breeding.

Comparative ripening of beef from grass-fattened and grain-fattened steers, N. G. BARBELLA, B. TANNOR, O. G. HANKINS, and R. E. HUNT. (U. S. D. A. coop. Va. Expt. Sta.). (*Jour. Agr. Res. [U. S.],* 64 (1942), No. 9, pp. 517–521).—No significant difference was found in the rates of ripening, flavor, aroma, or expressible juice of beef from steers about 2.5 yr. of age fattened on bluegrass pasture in comparison with beef from steers fattened in dry lot on corn, cottonseed meal, and hay. The comparative tests were carried on in 3 yr. with storage of similar prime rib cuts for averages of 15.7 and 50 days. The beef from different lots showed similar degrees of fatness of the eye muscle. Chemical tests of beef from the two groups in each test bore out the similarity of ripening. The sulfydryl content of the beef from the grass-fattened cattle was higher due to the higher sulfydryl content of the grass ration, but it had no bearing on the rate of ripening. The chemical indices of protein break-down were similar for both types of feeding. Two lots of 20 steers each were fed or carried in the pasture for about 5 mo.

Eastward sheep drives from California and Oregon, E. N. WENTWORTH (*Miss. Val. Hist. Rev.*, 28 (1942), No. 4, pp. 507–538).—An account of sheep drives and the shifting of "the surplus wool producing areas from eastern farm belt to canyon, mountain, and meadow of the great expanse from the High Plains to the Pacific coast."

Wool yields in the small side-sample as related to individual whole-fleece yields in four breed-groups of sheep, R. G. SCHOTT, E. M. POHLE, D. A. SPENCER, and G. W. BRIER. (U. S. D. A.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 137–144, fig. 1).—The fleece yields of 174 ewes were calculated from small-

sample yields from the middle of the right side using the formula $X = \frac{Y-a}{b_{y.x}}$,

wherein X is the whole sample yield. The values for a are -2.86 , -1.62 , -0.84 , and $+0.73$, respectively, for Rambouillet, Targhee, Corriedale, and Columbia ewes. The value of $b_{y.x}$ was 1.08 for all groups. A graph permitting reading whole-fleece values from small-sample yields for each breed is presented.

The limitations of oat straw as a roughage for maintenance, lactation, and growth in sheep, C. L. SHREWSBURY, C. HARPER, F. N. ANDREWS, and M. R.

ZELLE. (Ind. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 126-130).—Nonleguminous rations of yellow corn, corn silage, and oat straw, supplemented in different lots with casein, cod-liver oil, and alfalfa hay ash, did not produce optimum milk production in ewes as judged by the growth of the lambs. The experiment was conducted with 6 lots of 15 ewes each, the milk production being estimated by changes in the weights of lambs after nursing after 3-hr. separation from the ewes. A control lot received alfalfa hay in place of oat straw. In milk production the lots of ewes ranged in the order of alfalfa hay roughage and with supplements to the oat straw of casein and cod-liver oil, casein alone, no supplements, alfalfa ash, and cod-liver oil alone. The best gains before weaning were made by the lambs whose dams were on casein and cod-liver oil with the oat straw. Alfalfa hay was second, with casein as the single supplement to oat straw nearly as good. Cod-liver oil with oat straw and oat straw alone or with alfalfa ash did not stimulate growth so well. Twins did not do as well as singles, but they both showed similar responses to the rations.

The effect of fluorine in rock phosphate in the nutrition of fattening lambs, J. D. HATFIELD, C. L. SHREWSBURY, and L. P. DOYLE (Ind. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 131-136).—Varying amounts of rock phosphate containing 3.85 percent fluorine fed as a mineral supplement to yellow corn and alfalfa hay to lots of five lambs each furnishing 1.5, 3.0, and 6.0 mg. per kilogram body weight over a 170-day period were compared with no mineral supplement as to the gains, consumption, bone strength and ash, blood calcium and phosphorus, and thyroid weight and composition. In the lot receiving the largest amounts of fluorine by capsule grain consumption, weight of the thyroid glands, blood calcium, and breaking strength of the bone per unit of weight were reduced. Grain consumption and gains were greatest with the medium amounts of rock phosphate.

Nutritional deficiencies of a concentrate mixture composed of corn, tankage, soybean oilmeal, and alfalfa meal for growing pigs, T. B. KEITH, R. C. MILLER, W. T. S. THORP, and M. A. MCCARTY. (Pa. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 120-125).—The occurrence of a painful stiffness at 150 lb. live weight in 30 of 60 pigs started at 70-100 lb. on rations of corn, tankage, soybean meal, sun-cured alfalfa, and salt has been noted (E. S. R., 85, p. 95). The condition was first observed with a ration having a mineral content of 6-9 percent and low in manganese (0.0011-0.0014 percent). Additions of manganese sulfate (erroneously designated magnesium in the previous abstract) supplying 50-60 p. p. m. prevented stiffness but did not cure it. Feeding 0.2 lb. of manganese sulfate per 100 lb. of basal ration to young pigs, 26-40 lb. in weight, reduced the rate of gain as compared with those showing stiffness. Two of the 5 pigs so treated died. After feeding 100 gm. daily of pork liver for 63 days 1 pig gained 53 lb. In another experiment 40 pigs, 18-30 lb. in weight, were fed on the basal ration of corn, tankage, or tankage and soybean meal, with alfalfa for 56 days and produced emaciation, weakness, vomiting, and dermatitis. The nutritional factors required to prevent mild dermatitis and ataxia were not supplied by supplementing this ration with 100 gm. of brewers' yeast, 40 γ of beta carotene per day, a mixture of the B vitamins, or 100 gm. of beef liver per day. Limited responses were produced with supplements of alcoholic extracts of pork liver and a combination of soybean meal, yeast, and carotene. The nutritional factors required were not supplied by yeast alone or pure B vitamins.

The minimum requirement of pantothenic acid for the growing pig, E. H. HUGHES and N. R. ITTNER. (Univ. Calif. coop. U. S. D. A.). (*Jour. Anim. Sci.*,

1 (1942), No. 2, pp. 116-119, fig. 1).—A study of the growth of pigs on purified diets with varying amounts of pantothenic acid showed the minimum daily requirement for the growing pig was between 7.8 and 11.8 mg. per 100 lb. live weight. The experiment was conducted with four groups of five pigs each averaging 30.6 lb. per head. The amounts of pantothenic acid provided daily in the respective lots were 0, 3.6, 7.8, and 11.8 mg. per 100 lb., and the average daily gains over the 63-day period were 0.06, 0.4, 0.4, and 0.6 lb., respectively. The lack of pantothenic acid caused poor growth, hemorrhages in the digestive tract, and abnormal gait.

Pantothenic acid deficiency studies in dogs, A. E. SCHAEFER, J. M. MCKIBBIN, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 143 (1942), No. 2, pp. 321-330, figs. 3).—The requirement of growing puppies seems to be 100% of calcium pantothenate per kilogram of body weight per day, but less than this amount was required by the adult. Deficiency in this vitamin was characterized by prostration after 3-4 weeks on the basal sucrose-casein ration (E. S. R., 83, p. 236), supplemented with the essentials except pantothenic acid. Post mortem examinations showed severe fatty livers and abnormalities of the kidney, thymus, and intestinal tract. Blood studies showed that the plasma calcium in inorganic phosphorus remained essentially normal during the pantothenic acid deficiency. Delays in the response of deficient animals to oral or intravenous administration of pantothenic acid with and without glucose or liver extract was considered due to considerable repair of tissue damage being needed. Grayling in dogs with about 500% of pantothenic acid per kilogram would seem to eliminate the responsibility of this factor as claimed by Morgan and Simms (E. S. R., 84, p. 419). Choline supplements to the rations ruled out this as a cause of kidney lesions.

Types of fur fibers, T. M. P. and J. I. HARDY. (U. S. D. A. et al.). *Jour. Hered.*, 33 (1942), No. 5, pp. 191-199, figs. 5).—Microscopic examination of the skins and fibers of prime silver fox and mink pelts showed three main types of fibers to contribute materially to the quality, the under fur fibers, regular guard hairs, and the single guard hairs. Specialized hair was present in the tail gland and in a tuft near the navel. Permanent mounts were made with a plastic impression which revealed surface characteristics of fibers from different locations and different species.

Constituents of poultry feeds, R. V. BOUCHER. (Pa. State Col.). (*Flour & Feed*, 42 (1942), No. 12, pp. 7-8, 26-27).—Essentially a summary of the vitamin needs of poultry together with the feed sources of each.

The effect of diminishing the proportion of starch in the feed of laying hens, G. D. BUCKNER, W. M. INSKO, JR., and A. HARMS (*Kentucky Sta. Bul.* 423 (1942), pp. 18).—Substituting distillers' corn dried grains or other feeds low in starch for all or part of the yellow corn containing 60-70 percent starch in a ration of 29 laying hens over an 18-week period did not materially affect the number of pounds of eggs, dry shell, white, wet yolk, dry yolk, and fat in the yolk produced by these hens. However, analyses of the bodies showed an average of 0.62 lb. of fat per hen in those which had received 53.5 percent corn meal as compared with an average of 0.14 and 0.15 lb. of fat per hen in groups in which all the corn was replaced by low starchy feeds. The fat in the body of the laying hen appeared to be derived primarily from starch and not from protein or fat, confirming previous findings in growing chicks (E. S. R., 80, p. 529). Egg yolk fat was affected less by the ration than body fat, and there was no correlation between the color of the yolk and the hatchability of the eggs. The addition of distillers' corn dried grains in the mash did not interfere with palatability, but it seemed to have a deleterious effect on the health of the birds. The oil in the

urophygeal gland was smallest in birds receiving rations containing the largest amounts of corn. Data are presented on the composition of the feeds and representative samples of the uropygeal oil in the glands, body fat, droppings, and eggs after the 18-week period on the test ration in comparison with feeding on the control ration with more than 50 percent yellow corn.

The study of calcium metabolism in the laying hen by the comparative slaughter method. C. L. MORGAN, J. H. MITCHELL, R. C. RINGROSE, and E. J. LEASE. (S. C. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 212-215).—During the period following the onset of laying the hen goes into a negative calcium balance, even though she may be supplied with ample calcium in the ration. Such hens later remove calcium from the skeleton and the calcium is regained without cessation of laying. These conclusions were derived from comparative analyses of 11 hens at the onset of laying, for 6 hens in metabolism trials for 6 weeks, and for 6 hens after several months of production. The percentage calcium in the live weight before laying was 1.065, after 6 weeks' laying 0.85, and after several months' production 1.045 on rations containing 2.4 percent calcium and 15.94 percent protein. Like results were obtained with the hens in metabolism cages and in laying pens, and by Common and Hale (E. S. R., 87, p. 409).

Studies in mineral nutrition of laying hens.—I, The manganese requirement. M. S. GUTOWSKA and R. T. PARKHURST. (Mass. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 277-287, figs. 5).—Laying hens fed rations for 12 lunar months containing 17-74 p. p. m. of manganese were in normal physiological condition. Good production, fair egg size, egg texture, normal fertility, and hatchability were attained by all groups. Body weight, hemoglobin content of the blood, and ash in the bones were physiologically normal. On the other hand eggshell breaking strength, eggshell weight, and yolk weight were slightly greater with the higher manganese rations. The study was conducted with 2 groups of 48 Single Comb Rhode Island Red pullets with an all-mash ration to which supplements of commercial ground limestone or plain calcite flour were added.

The controlled feeding of laying pullets. H. TEMPERTON and F. J. DUDLEY (*Harper Adams Util. Poultry Jour.*, 27 (1942), No. 4, pp. 73-76).—Limiting groups of crossbred poultry to 20 and 40 percent potato meal with 30 and 50 percent town waste showed that there was a slight lowering of egg production, and when the feed was restricted to 3.48 oz. per head daily the egg production was substantially lowered. Similar results were obtained in regard to body weights. It thus appears definite that although the efficiency of production may be increased by smaller amounts of feed the total production of eggs and weight are reduced.

Making the most from pasturage for chickens. D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bmo. Bul.* 215 (1942), pp. 59-62, fig. 1).—The use of clover and bluegrass range or other succulent feeds as sources of vitamins A, D, and riboflavin is recommended as a supplement for the chick starter ration to 7-8 weeks of age, followed by the grower ration including whole oats and yellow corn.

Effects of nutrition on variability in the growth of chickens. J. C. HAMMOND and H. R. BIRD. (Md. Expt. Sta. coop. U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 230-242, figs. 2).—An analysis of the growth in 40 lots of 25 chicks each at the Beltsville Research Center with differences in the physical composition of the rations and nutrients supplied showed that variability in growth may be increased and prolonged by any defect in the diet which prevents normal development. Variability was reduced by individual rationing

and by partial starvation. A partial deficiency of vitamin A and large quantities of indigestible material as ground paper increased variability. Dextrinized starch had a more adverse effect on growth than paper flour but did not affect variability. Chicks fed individually and on diets low in pantothenic acid showed low variability as also was the case with excessive amounts of vitamins. Correlations of the weights of 130 chicks at intervals showed that live weight was more closely correlated with following weights than with those preceding. With the variability encountered it is pointed out that differences in the efficiency of feed utilization will become smaller as live weight increases. The distribution of variability in chick weights should be considered before starting an experiment and the number and age of chicks needed. "Under usual conditions it takes twice as many chicks at 6 weeks of age to demonstrate the significance of a 20 percent difference between means as it does at 14 weeks of age or older." Because of sexual variations, more chicks were required after 4 weeks of age to demonstrate significant differences if ♂s and ♀s were both considered than if they were fed separately.

Further observations on choline and yeast in chick nutrition, P. R. RECORD and R. M. BETHKE. (Ohio Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 271-276).—Approximately 0.15 percent of choline was needed by the chick to give maximum results in growth. Some other factor or factors similar to the alcohol-precipitate factor of yeast (R. of Schumacher et al.) (E. S. R., 84, p. 94) was also essential. Soybean phosphatides and lecithin to the extent of 1.5 percent of the basal ration were effective in promoting growth and controlling perosis. Additions of 0.15 percent methionine increased growth but did not prevent perosis. These studies were conducted in four experiments with tests of the supplements added to a basal ration of corn meal, peanut meal, casein, cane molasses, soybean oil, and minerals and vitamins received in lots of 20 and 14 chicks each during an 8-week period.

The interrelationship of manganese, phosphatase, and vitamin D in bone development, G. F. COMBS, L. C. NORRIS and G. F. HEUSER. (Cornell Univ.). (*Jour. Nutr.*, 23 (1942), No. 2, pp. 131-140).—It was found that the bone phosphatase of the femur and tibia of rachitic chicks was increased to abnormally high levels as reported by Robison for the rat.³ The bone phosphatase was decreased to approximately normal levels by the omission of excess manganese from the ration of chicks on a rachitogenic diet, but was about doubled when manganese was included. However, with the omission of manganese the perosis index was very high. These results showed an intimate relation between phosphatase activity of the bones and the manganese content of the diet. These studies were conducted in two experiments with lots of 6-14 chicks each receiving basal rations containing either cod-liver oil supplying vitamin D or 5-7 mg. of manganese per 100 gm. of ration or both. The chicks were fed to 4, 6, and 8 weeks of age.

A study on the administration of hesperidin, ascorbic acid, and massive doses of vitamin D to vitamin K-deficient chicks, J. T. CORRELL and E. C. WISE (*Poultry Sci.*, 21 (1942), No. 3, pp. 256-259).—Supplementing diets with massive doses of vitamin D, ascorbic acid, or hesperidin (a source of vitamin P which prevented vascular permeability), had no effect on the hemorrhagic syndrome manifested by chicks on a ration deplete in the antihemorrhagic factor. The results did not seem to rule out the possibility that increased fragility or permeability of the blood vessels of vitamin K-deficient chicks is not due to a lack of some factor other than vitamin K. Evidently the hesperidin had no

³ Biochem. Jour., 17 (1923), No. 2, pp. 286-293.

effect on the hemorrhagic condition manifested in cases of severe vitamin K depletion.

Vitamin K storage and prothrombin levels in chicks obtained from injected eggs, R. T. TIDRICK, F. W. STAMLER, F. T. JOYCE, and E. D. WARNER (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 438-440, fig. 1).—In a study of the storage of vitamin K, experiments were conducted in which the synthetic vitamin (potassium 2-methyl-1,4-naphthohydroquinone disulfate) at 200- and 1,000- μ g. levels was injected into eggs prior to incubation. At hatching the chicks from these eggs and chicks from the uninjected control eggs were placed on a vitamin K-free diet, and prothrombin determinations were made on blood obtained from individual chicks bled at 3- to 6-day intervals. The blood findings, presented graphically, together with observations as to spontaneous hemorrhage in the chicks, showed that the injected vitamin protected against the rapid and extreme fall of the prothrombin level which occurred when chicks are placed on a vitamin K-free diet.

Gizzard lesions in day-old chickens, D. MILLER and H. W. TITUS. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 203-211, fig. 1).—In slightly more than 99 percent of 28,458 day-old chicks evidence of gizzard erosion was found. The average severity score of the gizzard lesions decreased more or less steadily during the first 6 days after hatching. A variety of feeds included in the rations of the parent stock and substances injected in the eggs at different stages of incubation had no influence on the incidence or severity of the gizzard lesions based on the extravasation of blood. "Apparently the presence of lesions in the gizzards of young chickens has little or no demonstrable effect on their growth."

Minerals in rations of battery brooder chicks, V. G. HELLER and R. PENQUITE. (Okla. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 247-252).—A low calcium-phosphorus ration supplying less than 0.5 percent of each of these minerals was found which gave excellent growth in battery-fed chicks when 16.27 percent protein was fed. Casein was included in the ration and it was assumed responsible for the favorable growth and development of the chicks. Additions of calcium and phosphorus salts, singly and in combination, in different lots lowered growth and increased the malformations in the leg bones. Calcium supplements depressed the inorganic but not the organic phosphorus of the blood. It was also noted that high-phosphorus supplements reduced the inorganic calcium. Manganese may have value in assisting in the prevention of perosis by lessening the inhibiting effect of high mineral supplements, but it did not alter the blood constituents. These studies were based on determinations of the weights and defective leg bones of groups of 25 chicks each fed on a basal ration with supplements of buttermilk, casein, and minerals, singly and in combination.

Feed and other costs of producing market eggs, T. C. BYERLY (*Maryland Sta. Bul. A1* (1941), pp. 29, figs. 4).—The partition equation, $F = 0.523W^{0.403} \pm 1.126\Delta W + 1.135E$, was developed for a comparison of egg production and feed consumption of fowls of varying weights. The data were based on individual records of 102 laying hens, ranging in weight from 653 to 3,253 gm., and individually housed in cages from January to August 1940. In the equation F indicates the feed consumption per bird per day, W the body weight, ΔW changes in body weight, and E the weight of egg substance produced per day. Special arbitrary formulas were also developed for birds of the Leghorn and heavy breeds. Changes in body weights, feed consumption, and egg production must all be considered in establishing principles for general guidance. It was calculated that the feed requirements for maintenance without gain or loss in body weight ranged from 46.8 lb. for 3-lb. birds to 81.4 lb. per year for 7-lb. birds. For

each 100 standard weight eggs there were needed 14.2 lb. of feed above maintenance regardless of the weight of the hen. Thus, the maximum gross feed efficiency varied from 46.3 for 3-lb. birds to 34.3 percent for 7-lb. birds. The second part of the bulletin discusses the importance of various factors such as egg production, feed costs, overhead, mortality depreciation, and labor income from egg production in Maryland. Tables and graphs are included for use in calculating the effects of the major cost factors on net cost of producing market eggs.

Limited range for growing turkeys, T. T. MILBY and R. B. THOMPSON. (Okla. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 243-246).—In 2-yr. experiments little difference was found between the gains of turkeys on Bermuda grass ranges limited to 25-40, 50-75, or 300-500 sq. ft. per bird and moved to fresh range at weekly intervals. A mash containing 20 percent protein and scratch feed of whole grains was made available. Growth was significantly retarded and feather pulling became prevalent in birds confined to 10-15 sq. ft. per bird. When those confined were given access to a small bare yard no differences in the rate of growth were noted from those having access to more ample range, but feed consumption per unit of gain was slightly greater. No differences in mortality could be attributed to the method of range management.

The vitamin D requirements of turkey poults, J. S. CARVER and M. RHIAN. (Wash. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 260-262).—In studies with 20 lots of 15 poults each it was found that 80 or more A. O. A. C. chick units of vitamin D per 100 gm. of the ration were required to produce maximum growth and satisfactory calcification of the tibias. With smaller amounts of vitamin D, growth and ash contents of the tibias were reduced. These studies were conducted on the ash contents of the tibias of 10 duplicate groups of 15 poults each when different doses of fortified cod-liver oil were supplied.

The pigeon, W. M. LEVI (*Columba, S. C.: R. L. Bryan Co., 1941, pp. XXXII+512, [pl. 1, figs. 784]*).—A comprehensive account of the pigeon, including a description of the breeds and varieties, anatomy, physiology, and inheritance of color and morphological characters, with practical consideration of feeding, management, and diseases and parasites, is given. The different types, breeds, and genetic characteristics are briefly and completely illustrated.

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products in Illinois] (*Illinois Sta. Rpt. 1938, pp. 140-149, figs. 3*).—Results are briefly reported on the influence of rest periods for dairy cows on their subsequent milk production, by W. W. Yapp; the development of new feeding standards for milk cows and goats, by W. L. Gaines; the use of hybrid corns, soybeans, and alfalfa for silage and the returns secured from various types of dairy pastures, both by Yapp and W. B. Nevens; the bacterial population of ice cream, the relation of exposure time and temperature to effective destruction of bacteria in milk, and the value of resazurin for grading milk, all by J. M. Brannon and M. J. Prucha; and factors affecting the keeping quality of butter in cold storage, by O. R. Overman, O. F. Garrett, and H. A. Ruebe.

[Experiments with dairy cattle and dairy products in Pennsylvania] (*Pennsylvania Sta. Bul. 414 (1941), pp. 6-8, 10-13, fig. 1*).—Results are briefly reported for the following investigations: The economy of heavy grain feeding to dairy cattle, by A. A. Borland; the carotene requirements of dairy calves and the value of green hay in meeting this demand, by S. I. Bechdel and H. Keener; a milk cooling device involving motion of the milk cans along with agi-

tation of the cooling medium, by J. E. Nicholas; a comparison of various types of homogenizing machines for the homogenization of whole milk, by F. J. Doan; the factors involved in maintaining quality in frozen cream, by C. D. Dahle; the value of oat flour as an antioxidant in milk, by Dahle and D. V. Josephson; the use of calcium or sodium propionate or propionic acid for inhibiting mold growth in Cheddar cheese, by Dahle and F. G. Warren; and the value of manganese and iron salts in stimulating growth of certain types of bacteria which are desirable in dairy products, by T. G. Anderson.

[Experiments in dairying in South Dakota] (*South Dakota Sta. Rpt. 1941, pp. 25-34*).—Investigations, for which results are reported by T. M. Olson, G. C. Wallis, and D. H. Jacobsen, include sorghum-alfalfa silage v. corn silage for milking cows; the relative value of ground corn and ground sorghum grain in dairy rations; the influence of the fineness of grinding grains on their utilization by dairy cattle; flavors imparted to milk and butter by French weed, wild onion, and peppergrass; factors affecting the vitamin A and D content of roughages; the relative efficiency of Jersey and Holstein cattle in utilizing vitamin D in their rations; the vitamin D requirements of dairy cows; and the influence of various cream-holding methods on the quality of the resulting butter.

Feeding values of silages and hays: Grass and corn silages for cows, sun-cured and artificially dried hays [and] grass and corn silages for heifers, [and] hay and grass silage for heifers, O. M. CAMBURN, H. B. ELLENBERGER, and C. H. JONES (*Vermont Sta. Bul. 482 (1942), pp. 12*).—In a double reversal feeding experiment with milking cows, molasses-grass silage of relatively high moisture content was slightly, though not significantly, less efficient than corn silage, 1.81 and 1.87 lb. of 4-percent milk equivalent being produced per pound of total digestible nutrients consumed on the respective rations. Live weight gains were much the same in each case. In two trials, each of 120 days' duration, comparing sun-cured timothy hay, artificially dried timothy hay, timothy-molasses silage, and corn silage as sources of nutrients for growing heifers, 7.4, 6.8, 7.2, and 6.0 lb. of total digestible nutrients, respectively, were consumed per pound of gain. Timothy grass-phosphoric acid silage supplied nutrients for growing heifers somewhat more efficiently than sun-cured, slightly musty hay from the same source, the total digestible nutrients used per pound of live weight gain being 7.0 and 8.1 lb., respectively.

Silage without molasses, C. B. BENDER and H. B. SPRAGUE (*New Jersey Sta. Cir. 439 (1942), pp. [4]*).—Combinations of crops suitable for ensiling without preservatives and materials which may be substituted for molasses as preservatives are discussed.

Relation of ascorbic acid and of oxygen to oxidized flavor in milk, J. G. LEEDER and E. O. HERREID (*Vermont Sta. Bul. 481 (1942), pp. 12*).—Samples of mixed herd milk cooled and stored under varying conditions following pasteurization were observed for oxygen and ascorbic acid content and susceptibility to oxidized flavor development. Surface-cooled milks lost more ascorbic acid and developed more oxidized flavor than did those cooled in a pasteurizing vat. Partial evacuation and storage of milk under a vacuum decreased the rate of ascorbic acid and oxygen losses and greatly inhibited oxidized flavor development. Oxygen and ascorbic acid were not lost from milk in the theoretical 1:11 ratio, indicating that oxidizable constituents other than ascorbic acid are involved in the manifestation of oxidized flavor. The ascorbic acid content of milk was not significantly altered by changes from winter to summer feeding, but oxidized flavor occurred more often during the barn-feeding period. Milks frequently exhibited oxidized flavor even though ascorbic acid remained, while, on the other hand, milk containing little ascorbic acid at the end of a holding period, frequently showed no oxidized flavor.

VETERINARY MEDICINE

Animal pathology, R. A. RUNNELLS (*Ames, Iowa: Collegiate Press, Inc.*, [2. ed., rev.], 1941, pp. XIII+590, figs. 184).—A revised edition of this work (E. S. R., 80, p. 680).

[Work in animal pathology and parasitology by the Illinois Station] (*Illinois Sta. Rpt. 1938*, pp. 86-95, 105-108, 122-129, figs. 8).—Reporting upon the work of the year (E. S. R., 82, p. 678) by R. Graham, C. A. Brandly, G. L. Dunlap, J. Sampson, N. D. Levine, L. E. Boley, B. W. Fairbanks, H. H. Mitchell, and H. R. Hester, reference is made to Bang's disease; *Tritrichomonas foetus* as a possible cause of early abortion in herds; efficiency of chaulmoogra oil in the treatment of John's disease; control of ketosis in cattle and sheep; baby pig disease; commercially prepared antigen for control of pullorum disease; increase in incidence of respiratory diseases of chickens; use of developing chicken eggs for propagating viruses; poultry losses great despite disease-control progress; and trichomoniasis, a disease rare in chickens, found in two flocks in the State.

[Work in animal pathology and parasitology by the South Dakota Station] (*South Dakota Sta. Rpt. 1941*, pp. 7, 24, 34-39).—The work of the year (E. S. R., 84, p. 813) reported by C. J. Franzke, L. F. Fuhr, A. N. Hume, T. M. Olson, A. L. Moxon, H. D. Anderson, O. E. Olson, F. J. LeBlanc, G. Gross, T. Wright, and J. Watson relates to bloat in cattle, arsenic for prevention of selenium poisoning, chenopodium for eradication of worms in lambs, and an antidote for oat hay (nitrate) poisoning.

Veterinary anaesthesia, J. G. WRIGHT (*London: Baillière, Tindall & Cox*, 1942, pp. VII+207, pls. 7, figs. [48]).

The sulfanilamide group of drugs—a review, H. J. MILKS (*Cornell Vet.*, 32 (1942), No. 2, pp. 162-176).

Effects of sulfanilamide, sulfapyridine, sulfathiazole, and sulfanilylguanidine upon colon-typhoid-dysentery group, C. A. LAWRENCE and K. D. SPRAGUE (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 3, pp. 696-700).—In vitro studies of several sulfonamide derivatives, the details of which are given in tables, indicate that sulfathiazole and sodium sulfathiazole are somewhat more effective than sulfapyridine and distinctly superior to sulfanilamide and to sulfanilylguanidine against the colon-typhoid-dysentery group. Feeding the several compounds in the diet to mice caused, with a single exception, a significant reduction of the number of coliform organisms normally present in the intestinal excreta. Sulfanilamide, under the conditions of this test, proved to be ineffective in lowering the fecal *Bacillus coli* count of the animals.

The pathologic tissue changes produced by sulfathiazole and sulfathiazoline in rabbits, J. A. KOLMER, with tech. assistance of A. M. RULE and L. GROSIN (*Jour. Lab. and Clin. Med.*, 27 (1942), No. 8, pp. 1043-1046).—In the experimental work reported, the details of which are given in tables, both sulfathiazole and sulfathiazoline were found to be of low toxicity for rabbits by oral administration. "Doses of 0.05, 0.1, and 0.2 gm. per kilogram twice daily for 10 days in succession (20 doses) were well borne with no fatalities. Neither compound showed any macroscopic or microscopic evidences of injury of the meninges, brain, or spinal cord. In dose of 0.05 gm. per kilogram twice daily for 20 doses neither compound showed any gross or microscopic injuries of the kidneys, liver, or spleen. Both compounds in dose of 0.1 and 0.2 gm. per kilogram twice daily for 20 doses showed injury of the kidneys largely due to obstruction of the tubules by crystals of acetylated compounds, sometimes associated with tubular necrosis. These were the most frequent lesions observed. Both compounds were about the same in their production. Both

compounds in dose of 0.1 and 0.2 gm. per kilogram twice daily for 20 doses were about equal in the production of injury of the liver, usually expressed as cloudy swelling sometimes associated with slight fatty degeneration and necrosis of the peripheral cells of the lobules. Both compounds in dose of 0.1 and 0.2 gm. per kilogram twice daily for 20 doses were about equal in the production of injury of the spleen, usually expressed by slightly hyperplastic changes in the germinal centers of the Malpighian corpuscles."

The influence of storage on the chemical composition of nicotine sulphate and copper sulphate drench, M. C. FRANKLIN and R. F. POWNING (*Austral. Vet. Jour.*, 18 (1942), No. 2, pp. 72-75).—The experimental work reported has shown that a copper sulfate-nicotine sulfate drench deposits a sludge on standing which can be prevented through the use of suitable stabilizing agents. It is pointed out that the use of such stabilizing agents serves no useful purpose, since sludge formation has no significant effect on either nicotine or copper sulfate concentration of the solution.

Fern (*Notholaena sinuata* var. *crenata*) poisoning in sheep, goats, and cattle—the so-called "jimmies" of the Trans-Pecos, F. P. MATHEWS. (Coop. U. S. D. A.). (*Texas Sta. Bul.* 611 (1942), pp. 15, figs. 2).—The feeding upon cloak fern (*N. sinuata crenata*), which grows in crevices and under rocks in the drier hills and mountains from central Texas on west into southern California and south into northern Mexico, causes a toxication in sheep, goats, and cattle known as jimmies. The toxicosis is characterized by sudden seizures of severe trembling which may be followed by sudden death from respiratory paralysis, both of which are induced by exertion. The affected animals show no indication of a morbid condition while grazing, but fatalities frequently occur as a result of the animals being driven as little as 100 yd. It is pointed out that the term jimmies as applied to the disease here described has no relation to the same term sometimes used to designate rayless goldenrod poisoning. Since the greatest loss occurs in sheep and is due to the westward movement of this industry, it is becoming one of the leading disease problems for this class of livestock in the Trans-Pecos. The grazing of this plant causes a slight to moderate loss in goats but probably none in cattle. The effects of grazing the plant may appear as early as the middle of November. Mortalities begin the first part of January and continue until about 3 weeks after other green feed becomes available in the spring. In the experimental feeding of this fern to sheep and goats, evidence of toxicity was obtained by walking the animals not earlier than 48 hr. after receiving the first dose of the plant. Recovery from the toxic effects of the plant required from 5 to 19 days, a period which agrees with range observations. Infested pastures should be devoted to goat or cattle grazing, and if sheep are maintained in such areas the pastures should be small and no attempt made to work the sheep during the winter months.

Nitrate reduction in relation to oat hay poisoning, O. E. OLSON and A. L. MOXON. (S. Dak. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 782, pp. 403-406, fig. 1).—The reduction of nitrates to nitrites in *Amaranthus retroflexus* (known as redroot) of high nitrate content was found to occur under varied conditions of temperature when the material is wet. The most rapid reduction occurs at temperatures around 40° C. and at pH levels between 7.0 and 8.0. *Bacillus subtilis* is thought to be the organism most important in the reduction.

Comparative study of meningopneumonitis virus, psittacosis of pigeon origin, and psittacosis of parrot origin, H. PINKERTON and V. MORAGUES (*Jour. Expt. Med.*, 75 (1942), No. 6, pp. 575-580).

Eimeria neoleporis n. sp., occurring naturally in the cottontail [*Sylvilagus floridanus mearnsii*] and transmissible to the tame rabbit, J. CANDIDO M. CARVALHO. (Iowa Expt. Sta. et al.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 3, pp. 409-410, fig. 1).

A note on the examination of nose, throat, and vaginal swabs and of dung samples for the presence of *Str. agalactiae*, J. HARRISON (*Vet. Rec.*, 54 (1942), No. 4, p. 51).—Nose and throat swabs were taken from 74 cows, all but 6 of which had been proved by Edwards' technic (E. S. R., 71, p. 99) to be suffering from streptococcal mastitis or harboring the organisms in the milk. Vaginal swabs were taken from 20 virgin helpers and 56 cows, of which 15 were found to be harboring *Streptococcus agalactiae*. No Lancefield group B streptococci were isolated.

Control of contagious abortion by the area plan [in Ontario], J. S. WEBSTER (*Canad. Jour. Compar. Med. and Vet. Sci.*, 6 (1942), No. 5, pp. 143-147).

Allergy: A review of the literature of 1938, [1939, 1940, and 1941], F. M. RACKEMANN (*Arch. Int. Med.*, 63 (1939), No. 1, pp. 173-194; 65 (1940), No. 1, pp. 185-212; 67 (1941), No. 1, pp. 207-234; 69 (1942), No. 1, pp. 128-158).—A continuation of this annual review (E. S. R., 80, p. 101) of the literature on allergy covering the years 1938, 1939, 1940, and 1941, presented with 111, 137, 134, and 165 references, respectively.

Effect of dilution of neutral mixtures of eastern equine encephalomyelitis virus and antiserum, M. E. PIERCE, J. E. KEMPF, and M. H. SOULE (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 3, pp. 604-607).—Following a review, presented with a list of 22 references to the literature, work is reported in which a neutral mixture of eastern equine encephalomyelitis virus and homologous antiserum was reactivated when a 1:100 concentration of virus with antiserum was diluted a hundredfold with 0.85 percent saline solution and allowed to stand at 26° C. (room temperature). It appears that reactivation will occur only in a balanced mixture of virus and serum and, furthermore, the extent of dilution is important.

Significance of neutralizing antibody in experimental equine encephalomyelitis—a consideration of its relation to the disease in man: Preliminary report, R. W. SCHLESINGER, I. M. MORGAN, and P. K. OLITSKY (*Jour. Amer. Med. Assoc.*, 119 (1942), No. 8, pp. 618-620, fig. 1).—It was found in the work conducted that specific immunization of rabbits protects against an intracerebral test inoculation of equine encephalomyelitis virus only when the antibody in the serum reaches a titer of 1:300 or higher. At this level antibody becomes demonstrable in the cerebrospinal fluid, and this is believed to be an indicator of its availability to the central nervous system. It had already been shown that a low titer of serum antibody in vaccinated young mice was sufficient to indicate resistance to peripheral inoculation of this virus. Subcutaneous injection of active western virus in adult rabbits may lead to clinically inapparent virus invasion of the central nervous system, characterized by high fever and preceded by the presence of virus in the blood. Such infection of the nervous system takes place at a time when antibody is being produced. Deservescence and recovery set in as the antibody titer of serum reaches 1:300 (at about 5 to 6 days after injection). Young (4 weeks old) rabbits, similarly injected, die of encephalitis before this antibody level has been reached. Infection of man with equine encephalomyelitis virus and its possible prevention by vaccination are discussed in the light of experimental findings.

Human equine encephalomyelitis and St. Louis encephalitis in California, 1939-1941, B. F. HOWITT. (Univ. Calif.). (*Amer. Jour. Pub. Health*, 32 (1942), No. 5, pp. 503-515, figs. 3).—A study of encephalitis in California,

based largely on the serum neutralization tests, is summarized for the 3 yr. 1939, 1940, and 1941. Of 498 human serums from cases of neurotropic virus disease in the central valleys, including poliomyelitis, 213 neutralized the virus of western equine encephalomyelitis, 55 of 475 serums only the St. Louis strain, and 62 both viruses. If the total amounts for the 3 yr. are considered it is shown that 140 tests are positive only to the western equine virus, exclusive of those in combination with the St. Louis strain, as compared with only 55 for the latter virus alone. The work reported is in continuation of that previously noted (E. S. R., 86, p. 683). A list is given of 19 references to the literature cited.

Experimental transmission of Saint Louis encephalitis to white Swiss mice by *Dermacentor variabilis*, R. J. BLATTNER and F. M. HEYS (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 3, pp. 707-710).—In experimental work the virus of St. Louis encephalitis was recovered from the bodies of engorged larvae of the American dog tick which had fed on infected adult Swiss mice. Under experimental conditions the St. Louis encephalitis virus was transmitted to young Swiss mice by the larval ticks. Normal adult mice upon which infected full-grown ticks had fed developed considerable resistance to intracerebral inoculation of virus.

Suggestions for a mastitis control program for use by practicing veterinarians, W. D. POUNDEN (*North Amer. Vet.*, 23 (1942), No. 5, pp. 309-313, figs. 2).

Studies in rodent poliomyelitis, I, II (*Jour. Expt. Med.*, 75 (1942), No. 6, pp. 611-649, figs. 6).—In the first contribution presented (pp. 611-629) C. W. Jungeblut, M. Sanders, and R. R. Feiner report upon further experiments with the murine strain of SK poliomyelitis virus. The second contribution (pp. 631-649), by M. Sanders and C. W. Jungeblut, deals with the cultivation of the murine strain of SK poliomyelitis virus. It was found that the murine virus may be grown in embryonic mouse brain-serum ultrafiltrate cultures. The virus fails to grow in embryonic chick tissue cultures or in fertilized egg preparations.

Toxoplasma infection in animals, P. OLAFSON and W. S. MONLUX (*Cornell Vet.*, 32 (1942), No. 2, pp. 176-190, figs. 11).—Report is made of *Toxoplasma* infections in six animals, including a sheep, cat, and four dogs. The disease was characterized by a sudden onset, short course, high temperature, and marked depression. The characteristic lesion was a widespread conglutination necrosis attacking the intestine, lymph glands, liver, and lungs. Marked fibrinous exudation occurred in the necrotic areas. Pulmonary edema was a common lesion. In the cat, necrotic lesions were present in the intestine and mesenteric lymph glands, while the lungs showed marked epithelial hyperplasia (adenomallike lesion). The sheep showed a diffuse, nonsuppurative encephalomyelitis. *Toxoplasma* were readily demonstrable in the lesions from all cases, and the infection was experimentally transmitted from one dog to a puppy, from which it readily spread to other puppies kept in the same pen and produced fatal infections.

Parasitism in relation to the livestock industry of the South, B. SCHWARTZ. (U. S. D. A.). (*Sci. Mo.*, 54 (1942), No. 5, pp. 448-454).

The microscopic examination of incubated milk samples: Method and application in detecting infection of the bovine udder, A. L. KLECKNER (*North Amer. Vet.*, 23 (1942), No. 6, pp. 386-389).

Calf vaccination against Bang's disease—the essentials of a good plan for New York, R. R. BIRCH (*Cornell Vet.*, 32 (1942), No. 2, pp. 115-118).

The examination of colostrum and milk for the presence of *Brucella abortus* and its agglutinin, L. H. SCRIVNER. (Univ. Wyo.). (*Jour. Colo.-Wyo.*

Acad. Sci., 3 (1941), No. 1, p. 15).—An abstract of further work conducted (*E. S. R.*, 82, p. 388).

Studies on copper deficiency of cattle: The fatal termination ("falling disease"). H. W. BENNETTS, R. HARLEY, and S. T. EVANS (*Austral. Vet. Jour.*, 18 (1942), No. 2, pp. 50–63, figs. 5).—As a result of further experimental investigation and a more detailed study of the pathology, the authors are led to regard sudden death, referred to as falling disease, merely as the terminal manifestation of severe copper deficiency and not a separate disease entity. The primary lesion is starvation atrophy of the myocardium due to direct and indirect effects of copper deficiency, with replacement fibrosis. A fatal termination is a product of the extent and distribution of the heart lesion and of the effects of various stresses during the spring months. Death is ascribed either to ventricular fibrillation or to heart block, although the evidence here is very incomplete. The pathology of fatal and nonfatal cases of copper deficiency has been compared. The only difference encountered is the glomerular lesion characteristic of sudden death.

Diseases causing encephalitis in cattle, S. H. McNUTT. (Iowa State Col.). (*Cornell Vet.*, 32 (1942), No. 2, pp. 127–134).

Studies on ketosis in dairy cattle.—IV, The effect of glucose therapy and pasture feeding in cases of clinical ketosis, J. C. SHAW, R. C. POWELL, JR., and G. C. WHITE. ([Conn.] Storrs Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 783, pp. 473–478, figs. 4).—A few typical cases which are believed to contribute to a better understanding of ketosis in cattle and more particularly of the antiketogenic effect of glucose in the treatment of that condition are presented.

Physiologic and metabolic aspects of acetonemia in cattle, M. H. ROEPKE. (Minn. Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 782, pp. 411–415).—It is pointed out that the large amounts of ketone bodies in the blood of animals showing ketosis should not be considered as toxic incomplete oxidation products of fat metabolism but as one of the normal means of utilization of fats for energy when sufficient carbohydrates are not available. Many high-producing dairy cows give a positive Ross test for urine ketone bodies during the winter months, whereas only a relatively small percentage of such cows show clinical symptoms of severe ketosis. The usefulness of the nitroprusside or Ross test for acetonemia may be greatly extended in cases where a positive test is obtained if it is repeated with a 1:10 dilution of the urine. Animals with a severe ketosis usually show a three or four plus reaction with a 1:10 dilution of urine. In this manner it is possible in most instances to distinguish between a mild or secondary ketosis and a severe or primary ketosis. The high ketone and low glucose levels of the blood in cases of severe ketosis indicate a carbohydrate deficiency and suggest the administration of liberal amounts of dextrose intravenously or orally.

A filterable virus from pneumonia and diarrhea of calves, J. A. BAKER (*Cornell Vet.*, 32 (1942), No. 2, pp. 202–204).—A filtrable agent was secured from cases of pneumonia and diarrhea of calves that produced a condition in mice similar to the natural disease. The transmission of the disease from calves inoculated intranasally with infected mouse lungs to normal calves by pen contact and the neutralization of the virus in mouse tests by serums from calves recovered from the natural disease further indicated that the virus came from calves. It is therefore concluded that an infectious pneumonia and diarrhea of calves is caused by a filtrable virus.

A further note on the incidence of *Trichomonas fetus* in slaughtered cattle from a Wisconsin abattoir, B. B. MORGAN and W. WISNICKY. (Wis

Expt. Sta.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 783, pp. 471-472).—In this further report (E. S. R., 86, p. 827) on *Trichomonas*, the incidence of *T. foetus* in 1,577 bovine uteri, all obtained from the same source, is noted. Only 2 of the pregnant group of 997 were positive for trichomonads. Thirteen positive cases of trichomoniasis were found among the 100 pyometras of the nonpregnant group of 580 uteri. Approximately 1 percent of the total slaughtered cows examined were positive for trichomonads. Examination of 211 bulls from the local packing plant failed to reveal any trichomonad infections.

Sulfanilamide affects normal cows unfavorably (*Pennsylvania Sta. Bul.* 414 (1941), p. 28).—Brief reference is made by A. K. Anderson to the effect of this drug upon normal cows.

The host specificity of sheep and cattle helminths, with particular reference to the use of cattle in cleansing sheep pastures, F. H. S. ROBERTS (*Austral. Vet. Jour.*, 18 (1942), No. 1, pp. 19-27, fig. 1).—With a view to determining whether cattle could be employed with safety to cleanse sheep pastures of helminths under a system of rotation, 7 of 14 species infesting the lambs previously grazed on a pasture on which five worm-free calves were afterwards placed were transferred to the calves. These were *Haemonchus contortus*, *Trichostrongylus colubriformis*, *T. axei*, *Strongyloides papillosus*, *Cooperia curticei*, *Trichuris parvispiculum*, and *Moniezia expansa*. The species which did not appear in the calves included *Oesophagostomum circumcincta*, *O. trifurcata*, *Trichostrongylus vitrinus*, *T. rugatus*, *Bunostomum phlebotomum*, *O. columbianum*, and *Dictyocaulus filaria*. All calves exhibited a resistance to infestation by *H. contortus* from sheep. After grazing for 6 weeks on a heavily contaminated pasture they exhibited only moderate infestations, and these, moreover, were rapidly eliminated. Attempts at reinfestation with larvae from sheep even after single passage through cattle, resulted at most in the establishment of only very small numbers of worms which could not maintain themselves. Calves which proved insusceptible to larvae from sheep were readily infested with larvae of a pure cattle strain. *T. colubriformis* established itself in the calves in fairly large numbers, but the infestations did not persist. *T. axei* occurred in the calves in only very small numbers, and these were gradually eliminated. The reactions of the calves to *C. curticei* were somewhat similar to those against *H. contortus*. The infestations with *C. curticei*, however, were larger and persisted longer. From field evidence it is believed, however, that *C. curticei* can persist in cattle for long periods only in the presence of sheep. Very heavy infestations of *S. papillosus* were rapidly acquired by all calves and then almost as rapidly disappeared. The short persistence of mature *M. expansa* in the two calves which became infested may indicate that this cestode is not well adapted to cattle, an opinion supported by the rarity of *M. expansa* in cattle in Queensland. *Trichuris parvispiculum* from sheep is apparently fairly well adapted to cattle.

From the point of view of using cattle to control sheep helminths in Queensland, *H. contortus* and *Trichostrongylus colubriformis* are the principal species to be considered. Cattle, it is believed, could be used with advantage to cleanse sheep pastures of *T. colubriformis*, providing the animals were permitted to remain in the pasture for some months. In the case of *H. contortus*, however, such a procedure would be dangerous because (1) low grade infestations may be set up in cattle, particularly young cattle exposed to *H. contortus* from sheep, (2) sheep are readily susceptible to larvae from sheep after passage through cattle, and (3) sheep may be easily infested with larvae of a pure cattle strain. It is also possible that in time the sheep strain may gradually adapt itself to cattle.

Field trials of control measures for parasitic diseases of sheep, W. E. SWALES, in collab. with P. E. SYLVESTRE and S. B. WILLIAMS (*Canad. Jour. Res.*, 20 (1942), No. 5, Sect. D, pp. 115-132).—Description is given of field tests of methods of helminth parasite control through anthelmintic medication of sheep flocks on the ranges, conducted during the years 1937, 1938, 1940, and 1941. Following the development of phenothiazine in 1939 as a practical and highly effective anthelmintic for sheep, medication of adult sheep before the pasturing season was found very effective in preventing nodular worm infections in lambs. One early spring treatment in 1940 and a similar one in 1941 reduced the incidence of nodular disease lesions to 0.65 per lamb, a reduction from the figures of 1938 of 99.1 percent in the lambs slaughtered in the autumn. In spite of no treatment of the lambs during 1940 and 1941, *Haemonchus*, *Monodontus*, and *Cooperia* were reduced to very low numbers, and no significant increase in other genera occurred. It is suggested that *Oesophagostomum* has been reduced to a level too low for subsequent recovery in these flocks unless it is reintroduced in new stock; thus this parasite can be considered as probably eradicated.

The effect of phenothiazine-salt mixtures on the development of parasite larvae in the feces of sheep, R. T. HABERMANN and D. A. SHORE (U. S. D. A.). (*North Amer. Vet.*, 23 (1942), No. 5, pp. 318-321).—Phenothiazine-salt mixtures offered to sheep in the proportions of 1:9 to 1:14 were effective in stopping the development of parasite larvae in the feces when the quantity consumed daily contained at least 0.5 gm. or more of the drug. The development of the larvae in the feces was arrested in 48 hr. after the administration of phenothiazine. It is pointed out that during the summer months, when the salt consumption of sheep is greatest, phenothiazine-salt mixtures of 1:9 to 1:14 concentration may be of value in controlling pasture contamination and thereby reduce the infection of animals grazing on pasture.

Treating pregnant ewes with phenothiazine, R. T. HABERMANN, A. O. FOSTER and O. J. HUMMON (U. S. D. A.). (*North Amer. Vet.*, 23 (1942), No. 6, pp. 390-393, fig. 1).—The experiments described and those reported by others indicate that phenothiazine is well tolerated by pregnant ewes. The findings show that the commercially pure chemical can be administered at a dosage rate of 25 gm. in the feed without risk to either the ewes or their lambs. It is pointed out that this makes it practicable to employ phenothiazine as a valuable adjunct to parasite control by removing the parasites during the winter in order to reduce contamination of spring pastures.

Pining in sheep.—II, Confirmatory experiments on its control by cobalt-rich fertilizers, J. STEWART, R. L. MITCHELL, and A. B. STEWART (*Empire Jour. Expt. Agr.*, 10 (1942), No. 37, pp. 57-60).—Further work here reported (E. S. R., 86, p. 389) has led to the conclusion that on farms where pinning in sheep is due to cobalt deficiency the increase in live weight and general improvement in the condition of lambs is sufficient to warrant top dressing with cobalt-rich fertilizers. However, "pinning" symptoms may be due to several causes other than cobalt deficiency.

Some diseases of feedlot lambs, F. THORP, JR. (Mich. Expt. Sta.). (*Cornell Vet.*, 32 (1942), No. 2, pp. 119-126).

A note on the occurrence in Australia of *Corynebacterium equi* in pigs, I. W. McDONALD (*Austral. Jour. Expt. Biol. and Med. Sci.*, 22 (1942), No. 1, pp. 27-29).—Report is made of the isolation of an organism, apparently identical with *C. equi*, from lesions resembling tuberculosis in the lymph glands of pigs.

Studies on anemia in dogs due to pyridoxine deficiency, J. M. MCKIBBIN, A. E. SCHAEFER, D. V. FROST, and C. A. ELVEHJEM (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 77-84, fig. 1).—The experimental studies

reported have shown that blood plasma iron is abnormally high in anemia due to pyridoxine deficiency in dogs. It drops to a low normal level during the remission with pyridoxine therapy. Total blood copper values are at a low normal level during the anemia and increase to normal during pyridoxine therapy. Following the immediate stimulation in blood formation afforded by pyridoxine therapy, there is a lag which may be overcome by addition of liver extract to the ration. This stimulation is apparently not due to thiamin, riboflavin, nicotinic acid, pantothenic acid, or choline.

Chastek paralysis in foxes—B₁ avitaminosis induced by feeding fish, R. G. GREEN, C. A. EVANS, W. E. CARLSON, and F. S. SWALE. (Univ. Minn. et al.). (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 782, pp. 394-402, figs. 3).—This contribution relates to work, an earlier account of which has been noted (E. S. R., 86, p. 534).

Distemper studies in ferrets.—I, Attempted conversion of a virus strain from a viscerotropic to a neurotropic form, L. M. HEATH (*Canad. Jour. Compar. Med. and Vet. Sci.*, 6 (1942), No. 5, pp. 125-129).—In the work conducted a fixed viscerotropic strain of distemper virus was modified by serial intracerebral passage so that it manifested purely neural symptoms in 6 and mixed visceroneural symptoms in 4 of the 10 passages made intracerebrally. Parallel subcutaneous passages on the other hand indicated that only 3 of the passages manifested any neural symptoms and these were mixed, while the remaining 7 were purely visceral.

An analysis of thirty thousand autopsies on chickens, H. A. HOFFMAN and D. E. STOVER (*Calif. Dept. Agr. Bul.*, 31 (1942), No. 1, pp. 7-30, figs. 44).—The results of autopsies on more than 30,000 chickens, made during a period of 10 yr. and which resulted in 17,071 diagnoses, are reported, the data being presented in graphs.

Nutritional diseases of poultry, C. D. LEE. (Iowa State Col.). (*North Amer. Vet.*, 23 (1942), No. 6, pp. 394-400, figs. 7).

The effect of the rearing environment upon the incidence of avian leucosis complex, C. W. BARBER (*Cornell Vet.*, 32 (1942), No. 2, pp. 194-202, figs. 2).—A high incidence of avian leucosis complex lesions was observed over a period of years among birds reared at the experiment station of the New York State Veterinary College. Of three groups of birds reared off the station grounds for 19 to 22 weeks, 0, 6.3, and 12.5 percent, respectively, were affected with the complex in contrast to 23 and 51 percent of the two groups of nonisolated controls. Birds isolated for periods of 4, 10, 19, and 22 weeks developed the complex to the extent of 46, 32, 13, and 10 percent, respectively, during a 400-day period. On the other hand, there was an incidence of 64 percent among the birds reared at the station. Birds that were raised in isolation environment developed the leucosis lesions much later in life than those reared at the station.

Newcastle disease in Victoria, H. E. ALBISTON and C. J. R. GORRIE (*Austral. Vet. Jour.*, 18 (1942), No. 2, pp. 75-79, figs. 4).—Description is given of two outbreaks of Newcastle disease which occurred in Victoria in 1930 and 1932. Cross-immunity tests indicate that the Victorian virus is immunologically identical with the virus of Newcastle disease.

The removal of the fowl tapeworm *Raillietina cesticillus* by short periods of starvation, W. M. REID. (Kans. Expt. Sta. et al.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 220-229, fig. 1).—Experimental data, together with the related technic employed in infecting chickens with the fowl tapeworm *R. cesticillus*, one of the most prevalent and difficult tapeworms to control, are presented. It was found that starvation of a fowl infected with this tapeworm for 24 to 48 hr. results in the loss of the strobila of the worm which may pass out whole in the

feces or in partially digested chains of segments. This starvation effect produces results similar to those claimed for certain recommended worm treatments which prescribe a starvation period before medication. It was demonstrated that the scolex is not affected by long periods of starvation since in one case scoleces survived 20 days without food in the gut of the host. When normal feeding habits of the fowl were restored the neck was able to regenerate a new strobila and gravid proglottids were again produced in from 1 to 4 weeks. A sudden change in diet or removal to strange surroundings may induce voluntary starvation of the fowl which may result in the loss of strobilae. The feeding of oats did not cause worms to be eliminated. Starvation of the host immediately after the intake of mature cysticercoids does not prevent the establishment of some of these cysticercoids, although more than the usual number appear to be lost. Growth does not occur in newly established worms until after food is present in the gut. The long term cycles, in which occurs a cessation of proglottid production similar to the described starvation effect, are independent of the feeding habits of the host. The treatment of tapeworm-infected chickens to remove strobilae only for breaking, the life cycle cannot be recommended. Regeneration of new strobilae is too rapid and the length of life of the parasite is too long in both the larval and adult stages to make such a procedure practical.

A list is given of 29 references to the literature.

Poisoning of turkey poults from whorled milkweed (*Asclepias gallioides*), G. W. STILES. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 3, pp. 263-270, figs. 2).—The loss of 3-week-old poults that were turned into a small yard where young milkweed plants were growing led to field observations, supplemented by feeding experiments, which indicate that this milkweed is toxic for turkeys. With young turkeys fed 1 gm. of milkweed per 100 gm. of turkey weight, spasms followed within about 1 hr. and usually death in less than 5 hr. after feeding. Immature, tender plants appeared more toxic than more mature weeds. Whorled milkweed is found in southern Colorado, southwestern Kansas, northern New Mexico and Arizona, southern Utah, and possibly in southeastern Nevada, in northwestern Oklahoma, and the Panhandle of Texas. The economic importance pertaining to losses in turkeys from eating this milkweed may be a serious factor in localities where this plant thrives abundantly. Every effort should be made to provide wholesome green feed for turkeys and to eradicate the milkweed from premises known to be infested.

AGRICULTURAL ENGINEERING

Engineering in wartime agriculture, A. P. YERKES (*Agr. Engin.*, 23 (1942), No. 4, pp. 117-119, 125, figs. 2).—Pointing out the known wide discrepancies in labor requirements for unit crop production, the author proposes as an engineer's problem the development of a program of transferring inefficiently employed farm workers to jobs in war industries or other agricultural sections where they can render more effective service. He believes it probable that this could be done on a considerable scale without reducing agricultural production appreciably, if at all. Among causes of inefficient utilization of available labor and equipment, the farming of too small an area and the use of horses where tractors would be more efficient are cited. The author holds it to be possible to establish norms for all the various field operations. This would permit a quick totaling of the amount of work done on any given farm for which the acreage of each crop and the operations performed were known. The total per worker, obtained by dividing the total by the number of workers employed, should furnish a fairly accurate basis for comparing the relative efficiency of different farms so far as

crops are concerned. For illustrative purposes he uses the supposition that the basis for calculating the units for each field operation is the amount of work done with a two-plow tractor, believing that this might be as satisfactory a base as could be found since it represents a size of power unit most commonly used and on which there is probably the greatest amount of information available.

Land, labor, machines—key factors in wartime agriculture, F. J. ZINK (*Agr. Engin.*, 23 (1942), No. 3, pp. 77-78, fig. 1).—The supply of machines now on farms is reported as below normal. The tendency is to increase the amount of machines on farms to compensate for the low rate of replacement during the depression years and to replace workers lost from agriculture since 1935 to date, now amounting to 905,000 persons, or about 9 percent of the average number of persons employed in agriculture during 1941; and to put into practice measures of improved agricultural efficiency made possible by improved engineering design, changing agricultural practices, soil conservation, sanitary regulations for dairy and meat production, and livestock feeding efficiency, as well as for labor saving. The 1942 machinery quotas average about 80 to 85 percent of the 1940 production, a lower percentage than the 1941 output, while quotas for attachments and parts are somewhat higher to offset the reduced supplies of the new machines in 1942. It becomes the individual farmer's problem to increase the land efficiency, increase labor efficiency to offset men no longer available, and increase the efficiency and use of time-saving machinery. The responsibility of the agricultural engineering profession is indicated as that of contributing its knowledge of engineering efficiency as applied to the treatment of agricultural problems.

[**Agricultural engineering investigations by the Illinois Station**]. (Partly coop. Ill. Nat. Hist. Survey, U. S. D. A., et al.). (*Illinois Sta. Rpt. 1938*, pp. 234-261, figs. 3).—These include notes by E. W. Lehmann, A. L. Young, and R. R. Parks on an increase of nearly 5,000 kw.-hr. in the consumption of current on a rural line serving nine cooperating farmers; study of septic tank dimensions, by Lehmann and A. M. Buswell; viscosity after hard use as a key to value of lubricating oils, and rubber tires and high compression as a source of new life for tractors, both by R. I. Shaw; dependence of efficiency of terraces upon maintenance, by Lehmann, R. C. Hay, and El. L. Hansen; influence of field and crop conditions on use of smaller combines, by Young and S. M. Elliott; methods of growing and harvesting soybeans, by H. P. Bateman, Elliott, and Lehmann; killing of insects attacking stored grain by drying, by R. H. Reed and M. D. Farrar; factors affecting the quality of stored wheat, by T. Cleaver, W. Ashby, W. A. Foster, W. L. Burlison, G. H. Dungan, Farrar, and Lehmann; and lespedeza weed control through cleaning of seed, by C. W. Veach.

[**Agricultural engineering investigations by the Pennsylvania Station**] (*Pennsylvania Sta. Bul. 414* (1941), pp. 4-6, fig. 1).—A. W. Clyde reports on an increase of plow draft due to parasitical friction, apparently greater in moldboard than in disk plows, and on adaptation of a field gun recoil mechanism principle to an automatic tractor release hitch, called a stop-hitch, to prevent share breakage in plowing where heavy stones are encountered.

[**Agricultural engineering investigations by the South Dakota Station**] (*South Dakota Sta. Rpt. 1941*, pp. 65-69).—R. L. Patty reports on the comparative costs and the condition after 16 years' service of galvanized and painted steel fence posts, L. F. Larsen and Patty on conversion of horse machinery for tractor farming and on tests of new materials and methods for farm building floors, Patty and H. H. DeLong on continued experiments in the use of rammed earth walls, and DeLong and Larsen on prevention of mechanical injury to barley.

[Agricultural engineering investigations by the Wisconsin Station] (*Wisconsin Sta. Bul. 455 (1942), pp. 5-8, 21-22, figs. 3*).—This report notes an experiment by L. F. Graber and F. V. Buralow with a "quick haymaker" or roller crusher which picks up the hay as cut and crushes the stems between rollers, the mixed hay having dried to 14 percent 24 hr. after crushing but only to 29 percent moisture content when cut without crushing; and simple methods of building temporary or permanent pen barns, by S. Witzel, E. Helzer, E. Zehner, and A. Elneron.

Surface and underground waters of Ohio, W. STOUT, C. V. YOUNGQUIST, and R. E. LAMBORN (*Ohio Engin. Expt. Sta. Cir. 43 (1942), pp. [4]+20, figs. 16*).—This circular contains a foreword by Director C. E. MacQuigg, followed by discussions of (1) the conservation of Ohio's water resources, by Stout; (2) the surface waters of Ohio, by Youngquist; and (3) the underground waters of Ohio, by Stout and Lamborn.

The first of these discussions calls attention to the existence of a serious water supply problem in Ohio, with current average consumption per capita of from 80 to 100 gal., constantly increasing with increasing industrial demands, spread of irrigation, and other growing uses. Practicable ground water supplies occur mainly over former river valleys buried by glaciation. Only about one-half the area of the State has these resources. Utilization of about one-twentieth of the average run-off would meet current needs, but there is need to "practice every known method possible to put water back into the ground wherever it can be restored."

The second paper briefly discusses gaging and flow measurements, rainfall, and reservoirs. The last-named subject is especially emphasized from the viewpoints both of supply and of flood control. "Control will consist of the construction of large reservoirs for storing of excess flood waters for release during drought periods. The benefits of such a program over a long period will greatly outweigh the cost."

The third paper takes up the subjects of water from glacial deposits (the source of the greater part of the ground water available in Ohio) and water from deposits of stratified rock. This discussion is based largely upon the geological map of the State. The authors conclude that "more than one-half of Ohio is so physically constituted through a thick blanket of glacial drift or through porous rock strata at the surface that the supply of ground water is ample to meet the common needs of the farm, factory, or town." In the remainder of the State, however, the supply of ground water is generally meager and uncertain.

Profile curves for open-channel flow, D. F. GUNDER. (Colo. State Col.). (*Amer. Soc. Civ. Engin. Proc., 68 (1942), No. 4, pt. 1, pp. 535-542, fig. 1*).—The author analyzes certain irregularities appearing in the surface profile curves for gradually varied flow under conditions in which the depth of flow is less than both the normal and critical depths. The equation of gradually varied flow in a wide rectangular channel is integrated for the case in which the Chézy coefficient is given by the Manning relation $C = 1.486 \frac{R^{1/6}}{n}$. The curves for a variable Chézy coefficient given by the Manning relation are sketched. It is concluded, in part, that the use of the differential equation of gradually varied flow at depths below both the critical and normal depths should be restricted, in that the Manning relation for the Chézy coefficient should not be used, although in most cases, from a theoretical standpoint, the Bazin or Ganguillet-Kutter relations are satisfactory; and that "perhaps the backwater curves in most texts are based on certain qualitative features of the equation of grad-

ually carled flow, plus a knowledge on the part of the writers of what these curves should look like."

Forest lysimeter studies under hardwoods, H. A. LUNT (*Connecticut [New Haven] Sta. Bul. 449 (1941), pp. 515-572, figs. 17*).—In the spring of 1938 the equipment previously described (*E. S. R., 77, p. 753*) was moved to a hardwood stand where the study was continued for 2 yr. longer. The results of this portion of the work are here presented.

Taken together, the study under hardwoods and the previous study under red pine show that, under the conditions of the investigation the amount of nitrogen which is leached into the soil from the forest floor of a normal, fully stocked stand may vary from 4 or 5 up to 25 or 30 lb. per acre per year. Of this, from 5 to 40 percent may be in the nitrate form, from 12 to 40 ammonia nitrogen, and from 40 to 75 percent organic nitrogen. Other materials washed out of the A₀ horizon in a year's time are total solids 300-700 lb., of which about 45 to 70 percent was organic matter; calcium from 12 to 32 lb.; magnesium from 1 to 10; potassium from 12 to 25; sulfur from 12 to 20; iron from 0.5 to 5; silica from 2 to 10; and phosphorus 0.5 lb. The bulk of this material is either taken up by roots or fixed in the soil so that only a very small portion of it goes deeper than 4 in. Nitrogen transformation may continue into the early winter, and the concentration of nitrogen and other constituents is frequently as high in winter as it is the rest of the year.

Comparison of the hardwood findings with those in the red pine plantation indicate some differences in acidity and composition of the leachate, but since the two studies were not carried on simultaneously and the two stands were dissimilar as to age, soil types, and previous history of the land, it is held inadvisable to stress differences observed in the two investigations.

Distribution of corn yields on farm terraces on the Shelby soil, A. W. ZINGG and D. M. WHITT. (*Mo. Expt. Sta. coop. U. S. D. A.). (Agr. Engin., 23 (1942), No. 4, pp. 126, 128, fig. 1*).—Corn was contour-drilled on the terraces, the point rows being placed on the back slope of the ridge on the upper portion of the terrace interval. The horizontal position, total weight of corn, and average surface-soil depth of each drilled row of corn were determined. The corn yield per acre for each row was calculated, the area comprising the row length and one-half the distance between adjacent drill rows of corn being used. When point rows were encountered, the yield was combined with an adjacent full-length drill row and the area and the row position adjusted accordingly. A graph of the composite of the surface and subsoil profiles for the three terrace intervals is given, together with a composite of the yield data on the interval. The average yield of corn for the entire interval was 28.5 bu. per acre, the average depth of surface soil being 0.84 ft. The graph representing the relation of surface-soil depth to yield indicates that an average yield of 31.2 bu. per acre could be expected if the surface soil were distributed uniformly over the entire interval, assuming that the surface soil would have been held in place and its fertility maintained under the present cropping system without the support of terraces. Other studies at the station indicate, however, that neither the soil nor the fertility would be maintained on this field without this support.

Drainage and flood-control engineering, G. W. PICKELS (*New York and London: McGraw-Hill Book Co., 1941, 2. ed., [rev.], pp. XII+476, figs. 153*).—About 95 pages of the original book (*E. S. R., 55, p. 376*) have been replaced by 125 pages of new or revised material. In the chapter on precipitation, a table of data on 54 of the more important storms over the United States has been added, together with similar data for the New England storm of 1936 and the Ohio Valley storm of 1937, and other material has been added to this chapter.

Also enlarged or brought up to date are the chapters on flood run-off, stream discharge measurements, flow of water in open channels (new data bearing upon Kutter's n both for stream channels and for floodways), and flood prevention by reservoirs. Only the chapter on drainage law remains unaltered.

Drainage as a conservation practice, L. A. JONES. (U. S. D. A.). (*Agr. Engin.*, 23 (1942), No. 3, pp. 97-98, fig. 1).—Noting that few realize the extent to which drainage has been practiced in the United States, nor the acreage of wet, swamp, and overflowed land susceptible to development at reasonable cost which still remains, the author gives a brief history of the development of agricultural drainage in the United States, from the first recorded drainage law, enacted by the Massachusetts Colony in 1702, and the New York State general drainage act of 1804 to modern practice. The need for costly machinery to permit economical construction of large drainage improvements and the resultant organization of drainage districts financed by bond issues paid for by assessments are briefly dealt with, and the present status is indicated on the basis of the U. S. Census Bureau records of acreage in organized drainage areas and acreage requiring rehabilitation of drainage improvements before the land can be made to produce the crop yields its fertility warrants.

Technique of determining shearing strength of soils: Progress report of a special committee of the soil mechanics and foundations division on the technique of soil tests, B. K. HOUGH, JR. (*Amer. Soc. Civ. Engin. Proc.*, 68 (1942), No. 2, pp. 255-263, fig. 1).—The committee reports conclusions drawn in part from a questionnaire requesting from testing laboratories (1) a detailed description of the equipment used for shear testing, (2) an outline of testing procedure including sample preparation, and (3) an explanation of methods of interpreting or applying test data to practical problems. In part, the conclusions are that the double-shear device seems better suited to empirical comparisons of different soil types than to determination of the actual shearing strength of soils. Choice between the direct-shear and the triaxial-shear testing equipment in any practical work depends on the nature of the individual problem. For research, the triaxial equipment appears to be more satisfactory, an exception being the stabilometer, which has certain construction features making it more suitable for empirical tests than for research. No testing equipment can be considered entirely satisfactory, except for empirical tests, until the state of stress that it produces in the specimen is definitely known. Testing procedure must be varied to fit each problem. Efforts to determine the shearing strength of a given soil will be discontinued. The committee believes that in some cases in actual practice the necessary data on soil characteristics may be assumed by an experienced soils engineer without any tests at all, at least for preliminary design purposes, provided he has a clear conception of stress conditions in the prototype.

Stresses in a curved beam under loads normal to the plane of its axis, R. B. B. MOORMAN (*Iowa Engin. Expt. Stu. Bul.* 145 (1940), pp. 64, figs. 28).—This report presents algebraic analyses of (1) the stresses in a curved beam of any cross section in which there is little or no bending moment induced in planes parallel to the plane of the axis of the beam, and (2) the circular-arc beam of I cross section loaded by single concentrated loads, together with the load and deformation measurements for comparison with results obtained from each analysis. Load and deformation measurements were made on a curved round steel rod and a curved I beam. The rod was bent cold and tested unannealed. The I beam was bent cold and tested in both unannealed and annealed conditions.

The conclusions drawn are held to form a sound basis for the determination of structural strengths of horizontally curved beams subjected to vertical loads.

Machining and related characteristics of southern hardwoods, E. M. DAVIS. (Coop. Univ. Wis.). (*U. S. Dept. Agr., Tech. Bul. 824* (1942), pp. 42, pls. 14, figs. 6).—Four-ft. test boards were collected by the Forest Products Laboratory from different sawmills scattered from Virginia to Texas and compared, together with northern black walnut, Central American mahogany, and standard furniture woods. Separate tests for planing, shaping, turning, boring, mortising, and sanding, and for the related properties, steam bending, nail splitting, and screw splitting, covered 50 samples of each species in each test. The machining trials closely followed commercial practices. Numerous samples of each wood were measured for specific gravity, rings per inch, shrinkage, cross grain, warp, and minor imperfections. Data obtained on about 25 woods show that a given species may give good results in some operations, fair in others, and poor in still others. The general utility of a wood must be judged by summing up its properties. These are here reported in statistical form. Some woods are adaptable to several operations, but others require exacting technics for satisfactory results.

Preservative treatments of fence posts: 1941 progress report on the post farm, T. J. STARKER (*Oreg. Engin. Expt. Sta. Bul. 9-C* (1941), pp. 5).—This is the 1941 progress report on an endurance test set up in 1927.

Good practice in concrete masonry wall construction, K. C. TIPPY (*Jour. Amer. Concrete Inst., 13* (1942), No. 4, pp. 317–328, figs. 4).—The author discusses some of the concrete masonry wall construction details which represent the difference between ordinary and good construction, such as strength, durability, and watertightness; the need for preshrinkage of moisture-laden masonry units before laying in a wall; the use of the proper mortar; adequate footings and foundations; use of proper lintels and sills; tying of partitions to exterior walls; expansion and contraction joints; and precautions with parapet and flashings, drains, and waterproofing practice.

The effect of change in moisture-content of the creep of concrete under a sustained load, G. PICKETT (*Jour. Amer. Concrete Inst., 13* (1942), No. 4, pp. 333–355, figs. 17).—The amount and rate of plastic flow in concrete under load has been found to depend upon the rate of drying. This paper presents a mathematical analysis showing that this is a natural consequence of nonuniform shrinkage and a nonlinear stress-creep relationship. The analysis further shows that shrinkage cannot account for additional creep unless inelastic strain not proportional to stress is produced. Results from experiments designed to test the applicability of the theory to concrete are reported.

Saving steel in reinforced concrete design, R. L. BERTIN (*Jour. Amer. Concrete Inst., 13* (1942), No. 4, pp. 281–287).—The author proposes the prompt modification of the institute's Building Regulations for Reinforced Concrete, with reference especially to emergency construction for temporary use. He outlines a proposed emergency code and sums up its principles with respect to steel conservation as follows: "(1) Let the concrete do all the work it is capable of doing, (2) such reinforcement as is used should be high yield point steel, and (3) liberalize the working stresses to an extent consistent with a safe but not excessive factor of safety."

Proposed specification for cast stone, C. G. WALKER ET AL. (*Jour. Amer. Concrete Inst., 13* (1942), No. 4, pp. 313–315).—The principal changes which have been made are an increase in compressive strength requirements from 5,000 to 6,500 lb. per square inch and a reduction in permissible absorption from 7 to 6 percent. The absorption period has been increased from 24 to 48 hr., and the lower limit of 3 percent on absorption has been eliminated.

Building electrical equipment for the farm, W. A. ROSS, W. P. BEARD, J. DEISS, and L. C. PRICKETT (Fed. Security Agency, U. S. Off. Ed., Vocat. Div. Bul. 209 (1940), pp. V+97, [pl. 1], figs. 44).—This bulletin is planned to provide teachers of vocational agriculture with reliable subject matter organized in usable teaching form to facilitate systematic instruction on building safe and simple electrical equipment for the farm. It contains a foreword by J. C. Wright; hints on planning farm wiring, maintenance, and repair; and directions and drawings for the following 10 specific construction jobs: Making an electric poultry water warmer and an ultraviolet reflector for poultry; building an electric pig brooder, hotbed, and stock-tank water heater; rigging up a portable electric motor; assembling a motor dolly; building an electric chick brooder and pen; and making an exhaust fan room-cooling unit and a combination electric room-cooling and garden-irrigating device. A list of over 200 uses for electricity on the farm, some commonly used electrical terms and their meanings, and references on electricity are also included.

An insulated electric soil pasteurizer, A. HUSTULID. (Minn. Expt. Sta.). (Agr. Engin., 23 (1942), No. 4, pp. 127-128, figs. 5).—The author briefly describes a box-type pasteurizer of 0.5 cu. yd. capacity and of the inside dimensions 28 by 29 in. and 30 in. deep, with four immersed 750-w. heating elements. The device is mounted on trunnions supported by a frame of 3-in. channel iron. Soil temperature curves show the importance of suitable moisture content, the temperatures close to the heating elements reaching a maximum of 250° F. in a run with soil of a moisture content of 22.7 percent, whereas this maximum reached 500° in a soil of 6.6-percent moisture content. A moisture content such that the soil is ready for use was found convenient. In comparison with a box made from 1-in. pine, the insulated pasteurizer was found to effect a saving of about 0.15 kw.-hr. per cubic foot per 90° temperature rise.

Efficient use of farm production equipment, H. H. MUSSELMAN (Michigan Sta. Cir. 183 (1942), pp. 16, figs. 7).—This circular contains brief discussions of power and equipment resources, the individual nature of the problem of appraisal and analysis of resources for each farm, making the most of machinery, optimum loads for tractors, training for farm jobs, field work suitable for women, practicability of cooperation, costs involved in the use of farm machinery, machine capacity, the fitting of the machine to the job, and time-saving suggestions. The topic dealt with most fully is that of costs, under which head are taken up indirect costs, with some discussion of depreciation, life of machines, interest, repairs and obsolescence, and a shorter method of calculating indirect costs; direct costs and their estimation; use of cost estimation figures; and cost comparisons.

Mechanical injury in threshing barley, H. H. DELONG and A. J. SCHWANTES. (Minn. Expt. Sta. coop. S. Dak. State Col.). (Agr. Engin., 23 (1942), No. 3, pp. 99-101, figs. 6).—The speed at which the cylinders operated best ranged from 5,000 to 6,000 ft. per minute for all three types of cylinders. Slower speeds left unthreshed heads and higher speeds resulted in too much cracking and skinning. The best clearance for the rasp bar cylinder was from $\frac{3}{8}$ to $\frac{1}{2}$ in. as measured to the tips of the bar serrations. The rubber-faced bar did its best work at a $\frac{1}{4}$ to $\frac{3}{8}$ -in. clearance. The spike-toothed cylinder did its best work with a lateral clearance between teeth of $\frac{1}{2}$ in. The actual clearance cannot be changed materially, but by raising and lowering of concaves the areas of the tooth surfaces passing each other can be greatly altered. Minor changes can be effected by either cylinder speed or concave clearance, but for major changes in operating conditions it is necessary to adjust both speed and concave clearance. When the three cylinder types were carefully compared

as to their ability to thresh barley without cracking more than 3 or 4 percent, the test data showed that all three types can be (1) adjusted to thresh properly, (2) set to let heads go through unthreshed, or (3) set to thresh too severely and cause much mechanical injury to the kernels. It is believed that the rubber-faced bar cylinder has a slight advantage in threshing adequately without cracking the kernels.

A homemade castor bean thresher, H. P. CLAY (*Agr. Engin.*, 23 (1942), No. 4, p. 135, fig. 1).—The machine described consists of an old truck tire mounted on a front wheel and spindle. This tire turns inside a piece of tractor casing with adjustable clearance provided. The threshing is done between the inside of the piece of tractor casing and the outside of the truck tire. After being rubbed out between the tires, beans and chaff drop through an air blast which separates the chaff from the beans. The beans are then divided into two streams and dropped onto two separating rollers where the threshed beans are separated from the unthreshed beans. The separation of the threshed and unthreshed beans is accomplished by the separating rollers carrying the rough unthreshed beans over the top, while the smooth clean beans travel off the end of the roller. The unthreshed beans are rerun through the thresher. One hundred lb. of threshed beans per hour is about the capacity of the present machine. The limit in capacity is in the separating rollers. The tire has from 50 to 100 percent more threshing capacity than the separating rollers. Analysis of clean beans collected from the rollers revealed the following: Beans with cracked seed coat 0.4 percent, beans not hulled (i. e., not removed by separating rollers) 0.45, free hulls and foreign material, less than 0.1, and perfect beans 99.05 percent. As threshing cylinder, a 32 by 6 tire slightly inflated and best run at from 80 to 90 r. p. m., was used. The concave consisted of about one-fifth of a 9 by 36 tractor tire. A wooden fan and separating rollers were made. A $\frac{1}{2}$ -hp. motor furnished more than sufficient power. The device is shown in a photograph, but no drawings are included.

Mung bean production, L. E. HAZEN. (Okla. A. and M. Col.). (*Agr. Engin.*, 23 (1942), No. 3, p. 101).—The mung bean is more drought resistant than the soybean and easier to harvest than the cowpea. Of the two varieties now grown, the golden and the green, the latter seems to produce heavier yields of seed and to grow taller, making it readily adaptable to combine harvesting. Yields of seed range from 20 to 30 bu. per acre during favorable seasons on good ground. The forage yield is increased by sowing with the ordinary grain drill, but maximum seed production is obtained by drilling in rows with the corn planter, using a kafir plate.

In threshing, the concaves are removed but all teeth left on the cylinder. Some cracking occurs unless the speed is reduced, and as a full blast of air is required at the riddles, most threshermen merely remove the concaves and depend on aftercleaning to remove dust and cracked grain. The small size of the seed and its nearly spherical shape makes the fanning mill job simple.

Field shelling of corn, R. F. SKELTON and H. P. BATEMAN. (Univ. Ill.). (*Agr. Engin.*, 23 (1942), No. 4, pp. 131-133, fig. 1).—The picker-sheller used was a two-row, pull-type, rubber-tired machine equipped with a cylinder sheller and cleaner instead of the regular husking unit and a 40-bu. overhead grain tank. A 1936 model low-compression, rubber-tired tractor was used to operate the picker-sheller. Regular gasoline was used. The low-gear speed, approximately 3 miles per hour, was used. The crew consisted of two men, one operating the tractor and picker-sheller and the other hauling grain from the field in a truck.

The lower cost of the field-shelling method as compared to present methods for areas greater than 45 acres results from combining the picking and shelling operations, reduced hauling costs, greater capacity of the machine, and a smaller power requirement. The greatest portion of the harvesting losses in fields yielding up to 66 bu. per acre was caused by the snapping rolls and gathering points. The high moisture content of field corn during the harvest season and the lack of satisfactory storage or drying facilities at present necessitates that field-shelled corn be sold from the field at a low market grade. Foreign material and damage caused by the operation of the machine did not result in a reduction of market grade.

Some engineering phases of grain storage, H. J. BARRE and C. F. KELLY. (U. S. D. A. et al.). (*Agr. Engin.*, 23 (1942), No. 3, pp. 79-82, 84, figs. 3).—This is a discussion of work thus far completed in a project being carried on by the U. S. Department of Agriculture with the cooperation of various State agencies, much of the work here taken up having been earlier reported upon by Kelly (E. S. R., 83, p. 687; 86, pp. 397, 840), Long and Cropsey (E. S. R., 86, p. 101), Burkhardt (E. S. R., 86, p. 397), and Fenton (E. S. R., 87, p. 125).

The down-draft metal corncrib, D. H. MALCOM (*Agr. Engin.*, 23 (1942), No. 3, pp. 83-84, figs. 5).—In the design here sketched and briefly described the author faces the ventilator cowl into the wind, carries the down-draft nearly to the bottom of a cylindrical 16- to 18-ft. bin through a 1-ft. centrally placed vertical duct, and distributes it through perforations in a central drum 2.5 ft. in diameter. The bin proper is 10 ft. in height, exclusive of its dome roof. It is provided with a perforated metal floor and a drain pipe run out from the bottom of the central air-distributing drum. The principle of central introduction of the dry air is taken from the work of Kelly (E. S. R., 83, p. 687) with ventilated wheat storage. The down-draft ventilator proved superior in various experiments to ventilators of the suction type.

Alternative silo types to meet war demand for steel, J. R. MCCALMONT. (U. S. D. A.). (*Agr. Engin.*, 23 (1942), No. 3, p. 82).—The author tabulates the requirements of reinforcing and other steel and the nails and anchors for specified sizes of various temporary and permanent silo types. He points out that a good permanent silo may cost less in the end per ton of silage stored, because the cost is distributed over many years, but a temporary or less durable silo will pay dividends in increased milk or beef production by furnishing storage for the much-needed silage in this emergency period.

Handling and shipping tests with new potatoes from Kern County, California, W. R. BARGER, G. B. RAMSEY, R. L. PERRY, and J. H. MACGILLIVRAY. (Coop. U. S. D. A.). (*California Sta. Bul.* 664 (1942), pp. 24, figs. 11).—Shipping (to Chicago and New York) and holding tests were made in 1938, 1939, and 1941.

Most of the commercial stock from this district is washed and shipped in 100-lb. sacks. At the peak of the harvest (June), the temperature of the tubers when loaded is between 75° and 90° F. Stock dug and washed in the morning may be as much as from 10° to 15° cooler than that dug in the afternoon. Ventilated shipments in June have a temperature of from 65° to 70° en route, with a somewhat lower temperature while crossing the mountains. Refrigerated shipments cool under shippers' rule 240 (initial ice only) to a point between from 45° to 50° on the third or fourth day en route.

Potatoes in 100-lb. sacks were hydrocooled from 80° to 50° in 15 min. by passing through a shower of 35° water and were carried in perfect condition. A load was precooled with car fans from 80° to 45° in 6 hr., but wind from the fans caused surface browning. Severe surface discoloration (browning) of

skinned tubers was reduced by refrigeration and was practically eliminated for the 7-day transit period by precooling in ice water.

In a comparison of the effect of immediate icing of cars with that of delayed icing, less deterioration occurred with immediate cooling to 50°, even though the temperature rose after the fourth day. Poorer results were obtained by slow cooling in which tuber temperature of about 70° prevailed for 2 days followed by 50° for the remaining 5 days of the test. The sticky skin condition of tubers near the bunkers of cars under refrigeration appeared to develop during the first 3 days en route while the tubers are cooling slowly under humid conditions and to be eliminated by precooling the tubers in ice water. When tubers infected with late blight were shipped, the size of the lesions increased, but there was no spread of the disease to sound tubers, whether icing at the first icing station or delayed several days. Exposure to wind or hot soil soon after digging increased surface browning in transit. Browning was found to result from the combined effect of excessive drying and of oxidation of cells injured by skinning and is not immediately noticeable.

Cotton-gin maintenance, C. A. BENNETT and F. L. GERDES (*U. S. Dept. Agr. Leaflet 216 (1942), pp. 8, figs. 2*).—On the basis of work previously noted (E. S. R., 76, p. 856; 79, p. 404; 81, p. 119; 85, p. 545), this leaflet provides a general guide for repairing and modernizing ginning machinery. The topics specifically dealt with are checking pneumatic cotton-handling equipment; inspecting drying, cleaning, and feeding equipment; putting gin stands in shape; modernizing gin breasts; necessary attention to gin saws; testing lint-doffing systems; ginning bearings, belts, and pulleys; providing pure seed-handling equipment; inspecting lint-handling systems; checking kicker, tramper, and press; maintaining gin building; and care of the gin during the idle season.

Spraying equipment for pest control, O. C. FRENCH (*California Sta. Bul. 666 (1942), pp. 42, figs. 31*).—The author discusses sprayers and related equipment in considerable detail of design and operating characteristics, explaining the principles of the various devices, their comparative merits and limitations, effects of variation in the mode of operation, etc. Under the head of fundamental mechanics of sprayers are taken up atomization of spray liquid; pump types and their characteristics; pressure regulators; nozzles, guns, and rods; pressure and its effects; pressure losses in hose and rods; and agitation. The topic of portable power sprayers covers engine-powered, power-take-off, and traction-driven sprayers; sprayer tanks; transport trucks and wheel equipment; towers; and mixing plants and refilling equipment. Stationary spray plants are dealt with under the subheads object of the stationary system, pump and mixing plant, piping design, installation of pipe lines, rate of spraying, original cost of stationary systems, and advantages and limitations of stationary spray systems. Discussion of portable pipe line systems takes up objective of portable systems, the portable pipe line, methods of using portable pipe line systems, and merits and limitations of portable pipe line systems. The treatment of air atomizing sprayers includes development and use, types of equipment, and atomizing characteristics of air-type sprayers. Weed sprayers are considered with respect to requirements of equipment, pumps for weed sprayers, and booms and nozzles.

Time- and labor-saving equipment for the laying house, D. C. KENNARD and V. D. CHAMBERLIN (*Ohio Sta. Bimo. Bul. 216 (1942), pp. 89-96, figs. 7*).—The equipment described is to be made mostly from wood to meet the current scarcity of galvanized sheet metal. A mash feeder for layers is shown in a photograph and described briefly. A trough for drinking water designed to be placed in the partition between two laying-house pens and provided with

drainage arrangements to prevent drip and spatter from reaching the floor litter, as well as to permit flushing and cleaning, is shown in a photograph and in one cross section drawing. Box nests, of which each compartment accommodates from four to six layers, can be so constructed as to take up only half the wall space required by single nests of the same capacity. Drawings for the construction of 2- by 4-ft. units accompany the description. Ready-made and home-made catching crates are discussed briefly and illustrated, as are hinged panels for catching.

Rural fire prevention. H. GIESE. (Iowa Expt. Sta.). (*Agr. Engin.*, 23 (1942), No. 4, pp. 120-125, figs. 12).—On the basis of 50 years' records of 150 county mutual insurance organizations and of various other data concerning farm and town fires in Iowa, the author concludes that most of the fire waste on farms is in dwellings and barns. Much can be accomplished if flues and heating systems are in good shape and all hazardous roofs are protected by spark arresters on the chimneys. Well-rodded barns and careful management in haying will prevent barn fires. Dwelling fires occur mainly in winter, whereas most barn fires occur in the summer.

Old persons, above 60 yr., or young persons, below 10, are the most likely to be killed or injured by fire. The greatest number of deaths, injuries, and livestock losses from fire do not occur at the same time as the greatest fire waste nor from the same causes.

AGRICULTURAL ECONOMICS

[Proceedings of the thirty-second annual meeting of the American Farm Economic Association] (*Jour. Farm Econ.*, 24 (1942), No. 1, pp. 1-353).—Included are reports and the following papers, with discussions, presented at the meeting held at New York, N. Y., December 27-30, 1941: Adapting Agricultural Programs for War Needs, by S. E. Johnson (pp. 1-16) (U. S. D. A.); Agricultural Programs for the Post-War Period, by E. C. Young and J. C. Bottum (pp. 17-34) (Purdue Univ.); Canada-United States Trade Relationships, by D. A. Skelton (pp. 35-41); Latin American Aspects of Post-War Agricultural Readjustments, by F. A. Linville (pp. 42-51); Transitions to the Post-War Agricultural Economy, by J. D. Black (pp. 52-74); Private Enterprise and Conservation, by S. v. Cirlacy-Wantrup (pp. 75-96) (Univ. Calif.); Public Policy and Action for Conservation, by A. C. Bunce (pp. 97-108) (Iowa State Col. and U. S. D. A.); Society and Conservation, by C. H. Hammar (pp. 109-123) (Mo. Expt. Sta.); Problems in Physical Evaluation of Soil Conservation Benefits, by G. W. Collier (pp. 124-138) (U. S. D. A.); Needed Developments in the Evaluation of Soil Conservation Benefits, by N. W. Johnson (pp. 139-156) (U. S. D. A.); Behavior of Prices of Farm Products During World Wars I and II, by J. M. Tinley (pp. 157-167) (Univ. Calif.); The Land Market and Farm Mortgage Debts, 1917-1921, by L. J. Norton (pp. 168-177) (Univ. Ill.); Agricultural Labor in the First World War, by H. Schwartz (pp. 178-187); Nutritional Science and Agricultural Policy, by M. L. Wilson (pp. 188-205) (U. S. D. A.); Toward a More Adequate Approach to the Farm Tenure Program, by K. Brandt (pp. 206-225); The Content of Land Economics and Research Methods Adapted to Its Needs, by L. A. Salter, Jr. (pp. 226-255) (Univ. Wis.); Recent Regional Changes in Farming and Probable Future Trends, by R. L. Mighell, C. W. Crickman, H. L. Stewart, and K. L. Bachman (pp. 256-284) (U. S. D. A.); Agricultural Workers and Social Insurance, by J. J. Corson (pp. 285-295); Hired Farm Labor Under Minimum Wage and Maximum Hours Regulation, by E. L. Warren (pp. 296-314); Important Considerations in Determining a Fair Price for Fluid Milk, by A. MacLeod (pp. 315-319); The Effect of Milk Control Programs on Cooperatives, by C. G. McBride (pp. 320-325) (Ohio State

Univ.); Some Economic Problems Encountered in Milk Control Administration, by N. J. Cladakis and A. J. Pollard (pp. 326-332); Milk Control in Canada, by J. P. Nadeau (pp. 333-339); and Problems of Graduate Students in the Rural Social Sciences (pp. 340-342).

[Papers on agricultural economics] (*Jour. Farm Econ.*, 23 (1941), No. 4, pp. 697-872, figs. 5).—Included are the following papers: Foods for Defense, by J. B. Canning (pp. 697-711); Fundamental Elements in the Current Agricultural Situation, by J. D. Black (pp. 712-725); An Agricultural Policy for Hemisphere Defense, by F. A. Linville (pp. 726-742); Social Conflicts and Agricultural Programs, by K. H. Parsons (pp. 743-764) (Univ. Wis.); Training of Personnel for the Rural Social Sciences, by M. R. Benedict (pp. 765-770) (Univ. Calif.); Economics of Joint Costs in Agriculture, by S. v. Ciriacy-Wantrup (pp. 771-818) (Univ. Calif.); Conservation—An Objective or an Ideal? by N. W. Johnson (pp. 819-832) (U. S. D. A.); Recent Development Among Farm Labor Unions, by H. Schwartz (pp. 833-842); Shape of Total Revenue Curves, by A. Kozlik (pp. 843-854) (Iowa Expt. Sta.); Insurance Aspects of Extra-Risk Mortgage Loans, by D. C. Horton (pp. 855-866) (U. S. D. A.); and Development of "Normal" Citrus Fruit Yields by Tree Ages for Use in a Yield Insurance Plan, by R. R. Botts (pp. 867-872) (U. S. D. A.).

[Investigations in agricultural economics and farm management by the Illinois Station, 1937-38] (*Illinois Sta. Rpt. 1938*, pp. 175-208, 212-233, figs. 9).—In addition to results previously noted, these findings are included and discussed:

(1) A table by H. C. M. Case, M. L. Mosher, and W. A. Herrington summarizing the business records, 1935-37, of 200 farms in the Farm Bureau Farm Management Service in northern Illinois and those of the 40 most profitable and 40 least profitable farms; (2) chart, map, and tables by P. E. Johnston, J. B. Cunningham, Case, and M. P. Gehlbach summarizing by counties and groups of counties the business records for 1937 from 1,877 farms and comparing the records by years 1928-37 of farms in the Farm Bureau Farm Management Service in Livingston, McLean, Tazewell, and Woodford Counties; (3) findings by E. J. Working as to changes in farm income and the causes of such changes; (4) a statement as to income, indebtedness, expenditures for living, etc., of 117 farm families in 1937 as shown by a study made by Case, N. O. Thompson, L. Bane, and R. C. Freeman; (5) tables and chart by Johnston and Gehlbach showing the cost per crop acre by years, 1930-36, for different types of power, the changes in the type of power during the period, the number of horses and mules on Illinois accounting farms, 1926, 1932, and 1938, and the effect of size of farm and type of power on certain production costs; (6) the average harvesting costs per acre in 1937 with combines of different sizes and types, as found in a study by R. C. Ross and B. R. Hurt; (7) findings by Johnston and Gehlbach as to cost of husking and cribbing corn in 1937 with 66 pull-type and 30 mounted two-row mechanical corn pickers; (8) findings as to credit needs and opportunities of Illinois farmers by L. J. Norton (coop. U. S. D. A.); (9) some findings as to land use, living conditions, school administration, etc., and suggestions for readjustments in Pope County based on studies of welfare conditions by D. E. Lindstrom and of land use by V. B. Fielder (U. S. D. A.); (10) a chart by Working showing indexes of returns, 1921-37, per bushel of corn fed medium, good, and choice steers; (11) a statement by R. C. Ashby as to the number of cooperative livestock shipping associations active in the State in 1937 and the number of members and livestock handled by the associations; (12) findings by Ashby and E. N. Searls as to operating costs of trucks used in hauling livestock, charges per ton-mile and per 100 lb.,

earnings of operators, etc.; (13) findings by Ashby as to the operation of live-stock auctions, expenses of conducting sales, selling charges, etc.; (14) some findings by Norton as to the amount of grain shipped in 1937 from points on the Illinois River and the radius of operation of a large centralized elevator on the river in 1936; (15) tables by R. H. Wilcox, C. S. Rhode, and J. G. Cash showing the cost of milk production for 90 herds in 1936 and 99 herds in 1937 in northern Illinois and the costs and profits per cow (15 herds in 1937) as related to milk production per cow; (16) findings by R. W. Bartlett as to the effects of retail prices of milk and consumers' income, 1930-36, on the consumption of milk and the relation, 1921-37, of price spread between the retail prices of milk and evaporated milk and the per capita consumption of canned milk; (17) findings by Bartlett in a study of 13 creamery truck routes in 1937 as to the relation of volume of all dairy products and of butterfat hauled per mile to the cost of hauling per mile; (18) tables by Johnston and V. W. Kelley summarizing the production costs, 1937, in 24 apple and 17 peach orchards and spray costs, yields, and profits or loss in 23 apple orchards; (19) a statement by J. W. Lloyd and V. A. Ekstrom regarding the storage, methods of marketing, sales outlets, transportation used, etc., of 114 apple growers in 1937; and (20) tables by Wilcox and L. E. Card showing for 66 poultry flocks in 1937 the costs and returns from eggs according to the number produced per hen and the effect of hen mortality on cost of egg production.

[Investigations in agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Buls.* 215 (1942), pp. 81-82, 85; 216, pp. 96-100, 113).—In Bulletin 215 an article is presented by F. L. Morison on the cost of handling hay by different methods based on data from 167 farms in northwestern and north-central Ohio. Included in Bulletin 216 is an article, by G. F. Henning, on Some Effects of the War on Livestock Marketing and Stockmen based on a table giving the slaughter of hogs, cattle, calves, and sheep and lambs under Federal inspection by months in 1941 and the monthly averages during the period 1937-41.

The usual indexes of production, prices, and income, by J. I. Falconer, are brought down through December 1941 and February 1942, respectively.

Variability in wheat yields and outputs.—I, Cycles or random fluctuations, V. P. TIMOSHENKO (*Wheat Studies, Food Res. Inst. [Stanford Univ.],* 18 (1942), No. 7, pp. [2]+291-338, figs. 12).—Are fluctuations in wheat yields and outputs systematic in some respects and consequently predictable to a certain extent, or are they wholly dominated by chance? The answer is that many fortuitous factors, of which weather is perhaps the most important, dominate fluctuations in regional yields and outputs of wheat, at least to such an extent that, even with close statistical scrutiny, it is difficult to detect systematic tendencies. The usual analysis of series on wheat yields and production into component parts, however, reveals "cycles" with an average duration of about 3.5 yr. which recur less irregularly than cycles in business. Cycles of 3 or 4 yr. are also characteristic of fluctuations in other crops, and they are the most frequent in business cycles.

[Milk production costs in Pennsylvania], W. L. BARR (*Pennsylvania Sta. Bul.* 414 (1941), pp. 8-10, figs. 3).—The range in total cost of milk production, average costs of hauling and marketing milk, and average costs and returns per cow are given. The data are based on records kept by 79 farmers in 1938, 53 in 1939, and 74 in 1940.

Latin America as a source of strategic and other essential materials (*U. S. Tariff Comm. Rpt.* 144, 2. ser. (1941), pp. IX+397, pl. 1, figs. 30).—This is a report on the strategic and other essential materials and their production and trade, with special reference to the Latin-American countries and the United

States. "In the report there are presented basic data on production and trade for 40 selected strategic and other essential commodities which can or might be obtained in part or in whole from Latin America. For the satisfaction of its requirements for these products the United States is dependent, at least partially, upon imports. Not all of the commodities listed as strategic have been included, inasmuch as certain of them cannot be secured in Latin America. This is either because they do not exist there or because the technical equipment and skill necessary to produce them are not available. Other commodities, though not considered strategic, have been included because they are essential in the production of industrial and war equipment and of materials for Army and Navy personnel and for civilians. Still other commodities were added because they are important in the diet and health of the Nation."

Part 1, Mineral Products, includes 20 products. Part 2, Agricultural, Pastoral, and Forest Products, includes the following: Abacá, babassu nuts, cacao beans, castor-beans, cinchona bark, coconut oil, coffee, copra, unmanufactured cork, flax fiber, flaxseed, hemp fiber, henequen and sisal, hides and skins, jute fiber, kapok, palm oil, quebracho wood and extract, crude rubber, and wool.

Farm tenancy in the United States, 1940-1941: A selected list of references, L. O. BERGDAW (*U. S. Dept. Agr., Library List 2 (1942), pp. 49*).—This list of 255 selected references supplements Agricultural Economics Bibliography 85 (*E. S. R., 83, p. 554*).

Characteristics of farm property assessments in Maryland after the last reassessment, E. E. MILLER and W. P. WALKER (*Maryland Sta. Bul. A2 (1941), pp. 31-72, figs. 6*).—This is the second of a series of bulletins (*E. S. R., 84, p. 538*) designed to reveal farm assessment problems in the State before and after the reassessment made in 1937-39. It describes in considerable detail the assessment rates for different kinds of land and livestock after the reassessment, compares the rates between counties, and contains basic information for contrasting the results of assessing under a variable method of procedure and the absence of uniformity in unit values.

Land assessments represented from 50 to 65 percent of total real estate assessments in most of the counties, and buildings from 35 to 50 percent, averaging 58 and 42 percent, respectively. Assessments against farm dwellings varied from approximately one-half to two-thirds of the assessed valuation of the buildings and averaged about 55 percent. Farm dwellings accounted for nearly 25 percent of the total farm real estate assessment, varying from 17 to 35 percent among the counties. Approximately 81 percent of total land assessments were against tillable land and 10 percent against woodland. Livestock assessments averaged only 8 percent of the assessments against real estate, ranging from 2 to 15 percent in different counties. Rates of assessment on tillable land showed the greatest variation. Those on woodland showed more variation between counties but more uniformity within the counties. Inequalities of livestock assessments among individuals arose from a failure to make a complete assessment coverage and to apply variable rates on units of livestock classes.

Problems of packaging vegetables for upstate New York markets, H. PLATENIUS ([*New York*] *Cornell Sta. Bul. 779 (1942), pp. 19, figs. 4*).—The findings of a survey made during the summer of 1940 principally on the regional markets of Syracuse and Menands, the Niagara Frontier Market of Buffalo, and the municipal market of Rochester are presented and discussed. The findings as to containers used, packaging costs, and variability in net weight of packages are summarized. The functions of the regional markets, the factors determining choice of packages, and the variability in net weight of packages

are discussed, and recommendations are made for changes in packaging practices in general and for specific crops.

Grade and price comparisons of Del-Mar-Va and Virginia broilers and fryers, R. E. MAI and J. M. GWIN. (Md. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 1, pp. 70-76, figs. 2).—"This study compares poultry produced and dressed on the Del-Mar-Va Peninsula, and the Valley of Virginia on a standard grade basis, and also gives the methods practiced in the marketing of Del-Mar-Va broilers. It also compares actual plant yields by grade from Del-Mar-Va and the Valley of Virginia with yields from middle western plants."

Effect of egg size and interior quality (as determined by candling) on egg prices, R. E. CRAY (*Ohio Sta. Bimo. Bul.* 215 (1942), pp. 76-81, figs. 5).—A table and chart show the average yearly premium per dozen paid for size and interior quality of eggs on the Wooster, Versailles, and Napoleon, Ohio, egg auctions, September 1, 1939-August 31, 1940. Charts show the seasonal variations on the Versailles auction during the same period. The relation of flock management to size and interior quality of eggs is discussed briefly. The average yearly premiums on the three auctions were: Large size over medium size—U. S. Extras, 4.6 ct., and U. S. Standards 3.5 ct.; and U. S. Extra quality over U. S. Standard quality—large eggs, 2.4 ct. and medium eggs 1.3 ct.

Crops and Markets, [April 1942] (*U. S. Dept. Agr., Crops and Markets*, 19 (1942), No. 4, pp. 85-104, figs. 2).—Included are crop and market reports of the usual type.

RURAL SOCIOLOGY

[Investigations in rural sociology by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 414 (1941), pp. 43-45).—The topics discussed include studies on the popularity of the Agricultural Adjustment Administration program, by P. I. Wrigley; the back to the country population movement, by H. R. Cottam; and poorly housed families as a social problem, by M. E. John.

Will history repeat in rural America? E. SCHMIDELER (*Rural Sociol.*, 6 (1941), No. 4, pp. 291-299).—Time and again in past history have lands become concentrated in the hands of a few owners, as in Rome under the Republic, Ancient Greece, and England, where the growth of large holdings began with the so-called "enclosure" of land for sheep raising, and even to this day the land is owned almost exclusively by a small handed-gentry. The system aimed at under the various Land Acts for the disposal of the public domain of the United States was the multiplication of small independent homesteads, but today the old homestead or family-size type of farm is being absorbed by the large-scale operator. The 1940 Census shows that a meager 1.6 percent of the farmers of the Nation—those farming 1,000 acres or more—now operate 34.3 per cent of all land in farms. Small farms—those of but a few acres—are also increasing, at least in number if not in total acreage, but the type of farm between these two extremes is losing its battle for existence. Outstanding among the causes of this change is the mechanization of agriculture. Little, if anything, is being done to check it or to offset its harmful effects.

Studies in the geography of population change, Canandaigua Lake region, New York, R. B. SIMPSON (*Rochester Acad. Sci. Proc.*, 8 (1942), No. 2-3, pp. 49-121, pls. 6, figs. 11).—The author describes and analyzes the changes in number and distribution of people inhabiting the Canandaigua Basin. Many similarities were found between the Indian occupance and that of the whites, even though the Indians were only one-tenth as numerous as their successors. Early Seneca history was marked by abandonment of the Allegheny Plateau in favor of the Ontario Plain, probably because of better agricultural conditions

on the lowland. Indian population had its periods of marked decline, although they were the result not so much of migration as of the Colonial Wars. At least one-half of the Senecas lived, as today almost half of the whites do, in a single village at the foot of Canandaigua Lake so large that if it were recreated it would rank as the third largest agglomeration in the region.

The density of rural population in the Canandaigua region is more than three times as great on level as on steep land, but differences in gradient are less important today than they were in 1860, thus running contrary to the general principle that, as civilization progresses, the returns from the farming of steeper lands diminish. This exception is the result of the spread of viticulture after 1860. The distribution of people throughout the Canandaigua Basin is a function of thickness of the A horizon of the soil and bears only slight relationship to the texture of that soil. Road condition has a direct effect upon population density. Those thoroughfares which are surfaced today have always had at least twice the population of those at present unsurfaced. As the pavement is actually applied, these differentials are increasing somewhat. The distance from the lake bears a direct relationship to population density, for the median distance of farms from Lake Canandaigua has been constantly declining throughout the region as a whole. The factors road type and distance from lake are increasing slightly in importance, while the others remain static or decline somewhat. The principle of comparative advantage, operating in a region which has only limited physical assets in the usual sense of the term, holds both the explanation of the past and the key to the future.

Population movements influenced by fertility of soil (*Illinois Sta. Rpt. 1938, pp. 208-210*).—An incompleeted study by D. E. Lindstrom indicated that ownership and income varied directly with soil fertility, whereas tenancy varied inversely.

Growth of population in Kentucky, 1860-1940, H. W. BEERS (*Kentucky Sta. Bul. 422 (1942), pp. 24, figs. 12*).—The author found that the trend of population in Kentucky was generally upward during the entire period from 1860 to 1940, with many minor differences in subregions and counties.

A camera report on El Cerrito, a typical Spanish-American community in New Mexico, I. RUSINOW (*U. S. Dept. Agr., Misc. Pub. 479 (1942), pp. [4]+136, figs. 81*).—This camera report on El Cerrito, N. Mex., is the first of six to be published by the Bureau of Agricultural Economics. Each deals with a community typical of an area or group in the United States and is designed to serve as a companion book for a series of six technical publications. That for El Cerrito has been previously noted (*E. S. R., 86, p. 697*).

Contemporary sociological research in farm family living, O. D. DUNCAN. (Okla. A. and M. Col.). (*Rural Sociol., 6 (1941), No. 4, pp. 300-310*).—It is stated that the great majority of family budget, or standards of living, studies which have been conducted in this country are neo-Engellian in character, although Zimmermann has succeeded in turning attention to a literal interpretation of Engel's Law and in bringing the original Le Play studies to a position of prominence in the United States. Most of our budgetary studies have adopted features of Wright's version of Engel's Law, traits of the original study by Engel, and characteristics of Le Play, but recently the technics of correlation analysis have been grafted upon the older Engellian approaches. Budgetary patterns are now being used as independent rather than as dependent variables, while the Wright-Engel approach has been modified almost indefinitely. Multiple factor indexes and scales of measurement are being perfected which give promise of producing radical changes in budgetary analysis.

Some sociological aspects of consumers' cooperation, L. C. KERCHER (*Rural Sociol.*, 6 (1941), No. 4, pp. 311-322).—This study of the Finnish-initiated consumers' cooperative movement in the North Central States demonstrates that a nexus of sociological factors conditions the successful initiation, development, and functioning of cooperative enterprise. These factors represent several major areas of sociological interest: Regional economic and ecological organization, population migration and settlement, cultural heritage and change, social aspects of personality, group organization and interaction, community structure, and institutional organization and functioning. Since every cooperative situation is in some respects unique, conclusions or generalizations drawn from the study of one cooperative situation must, of course, be applied with understanding and insight to another.

Cultural change and the country weekly, C. F. REUSS. (Wash. State Col.). (*Rural Sociol.*, 6 (1941), No. 4, pp. 332-338).—This article describes some adaptations made by the small-town newspapers in Washington to the social and cultural changes occurring in the rural environment. Among these adjustments are: A stability in numbers which has been reached at the expense of some loss of per capita circulation strength; a reduction in the number of two-newspaper towns; an increase in the size of the newspaper page; a shift from Saturday to Thursday as the second most important day of publication; a decreased interest in political parties and policies; and a concentration on local news, particularly of persons and organizations. These trends suggest certain observations on the process of change and adaptation in social institutions, which by nature are slow to change: Adjustment to change is forced upon an institution by the inroads of competing agencies; the stimulus to change comes from without, not from within the institution; and changes in any one of the four elements of any institution—rank and file membership, leadership, physical structure and equipment, and pattern of attitudes lending sanction to the operation of the institution—will evoke changes and adaptations in the structure and functions of the institution.

Rural youth in Indiana (18-28 years of age), L. ROBERTSON, H. F. AINSWORTH, O. E. BAKER, and N. T. FRAME. (Coop. U. S. D. A.). (*Indiana Sta. Bul.* 467 (1942), pp. 47, figs. 40).—On the basis of interviews of more than 1,200 rural youth in five counties, the authors found that economic problems were the most important for rural young women, but social contacts were comparatively important, more so than for young men. Other needs reported included employment opportunities, getting started in farming, improved recreational and social opportunities, health, education, and religion.

Rural youth and the Government's recreation program, A. W. GREEN. (Univ. Conn.). (*Rural Sociol.*, 6 (1941), No. 4, pp. 323-331).—Of all segments in our population, rural youth perhaps stands most in need of the facilities and organization of the W. P. A. Division of Recreation, but because of a confusion of ends, and the way the machinery of the Division was set up, it has had to concentrate its efforts in urban districts. A number of weaknesses inherent in the Division's program are described, and these are concretized by the inclusion of a personal-experience document secured from a Division worker.

FOODS—HUMAN NUTRITION

[Studies in foods and nutrition by the Illinois Station] (*Illinois Sta. Rpt.* 1938, pp. 136-139, 299-311, fig. 1).—Among these studies are freezing in relation to palatability of meat, by S. Woodruff, S. Bull, and E. R. Rogosheski (pp. 136-139); factors affecting the carotene content of corn, by J. Outhouse and

E. Kempster (pp. 299-301); and the cake-baking characteristics of flours from Illinois wheats, by E. Chambers and Woodruff (pp. 307-308).

[Nutrition studies of the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 414 (1941), pp. 27-28).—This progress report notes studies by N. B. Guerrant and R. A. Dutcher on the effect of exercise on the vitamin requirements of rats and on the nutritive factors involved in the development of achromotrichia in rats.

Estimation of the proximate principles of food in a few edibles by chemical methods, K. MITRA and H. C. MITTRA (*Indian Jour. Med. Res.*, 29 (1941), No. 2, pp. 315-323).—Data on proximate constituents and Ca and P, determined by A. O. A. C. methods, are reported for 13 kinds of grain foods, 18 of flesh foods, 27 of fruits, 13 of vegetables, and 9 of miscellaneous foods as consumed in Bihar Province. The foods are identified by local, English, and Latin names.

Balanced diets.—II, Studies on the nutritive value of fish, S. P. NIYOGI, V. N. PATWARDHAN, B. N. ACHARYA, and R. G. CHITRE (*Indian Jour. Med. Res.*, 29 (1941), No. 2, pp. 279-285).—Moisture, protein, fat, Ca, P, and Fe were determined, by methods noted, in the edible portion (proportion given) of 13 kinds of dried and 5 kinds of fresh fish obtained on the Bengal market. The liver oils of some of these fish were found to be several times richer than cod-liver oil in vitamin A content. The body fats did not contain vitamin A in appreciable amounts.

Nature's garden for victory and peace, G. W. CARVER (*Alabama Tuskegee Sta. Bul.* 43 (1942), pp. 18, figs. 9).—Edible wild plants commonly available in Alabama, classified by botanical families and designated by common and scientific names, are listed with brief descriptive notes and suggested methods of preparation for table use.

The effect of cooking on the nutritive value of vegetables, M. OLIVER (*Chem. and Indus.*, 60 (1941), No. 32, pp. 586-596, figs. 3).—This review, presented as an address, considers the effects of cooking on the various individual nutritive components in green leafy vegetables and in roots and tubers. The data presented include results obtained by the author in a study reported earlier (*E. S. R.*, 85, p. 570).

The Hamburgh parsley, S. DARK (*Nature [London]*, 148 (1941), No. 3744, p. 143).—This brief note concerns varieties, cultivation, and food value of this root vegetable. "The greatest merit of this vegetable as a wartime crop is its rich content of vitamin C which is available during the winter months. It has been found by a nutritional laboratory that roots which had been stored for 5 mo. still contained about 21 mg. of vitamin C per 100 gm., a much higher value than is known in any root vegetable except swedes."

Potato varieties: Sugar-forming characteristics of tubers in cold storage, and suitability for production of potato chips, F. E. DENNY and N. C. THORNTON (*Contrib. Boyce Thompson Inst.*, 12 (1941), No. 3, pp. 217-252, fig. 1).—The study reported earlier (*E. S. R.*, 85, p. 557) was continued with analyses of tubers of the 1940 crop and extended in that 14 varieties, in addition to the original 11, were studied; storage temperatures of 7° and 8.2° C. were introduced, in addition to the temperature of 5° (while tests at 10° were discontinued); storage was started at two different dates (October 25 and December 24) after harvest; and four (sometimes five) storage periods were employed, these varying from about 10, 17, or 18 days to as much as 144 days. In all, about 1,000 analyses for each of the two sugars were obtained, and potato chips were prepared from tubers sampled for sugar determinations.

The results, presented and discussed at length, confirmed the fact reported earlier that the concentration of reducing sugar and not that of sucrose deter-

mines the color of chips. Again it was found that tissue furnishing juice with more than 5 mg. of reducing sugar per cubic centimeter produced chips too dark brown in color and that the value should be as low as 3 mg. for a really satisfactory commercial color. Nine of the original 11 varieties showed nearly identical responses in the 2 yr. of test. Reducing sugar values of lots stored at 7° and at 8.2° were, respectively, only about 35 and 16 percent of the values at 5°. Delaying storage retarded the rate of increase of reducing sugar at 5°. At 7° storage temperature many of the varieties were kept at low reducing sugar values for periods of from 108 to 131 days after starting of storage. As far as sugar values were concerned 8.2° was also satisfactory, but sprouting was more extensive at that temperature.

Varieties of the Rural group (Neverblight, Russet Rural, Heavyweight, Carman No. 3, White Rural, Rural New Yorker, Number Nine, and Sir Walter Raleigh) and Chippewa and Blue Victor maintained low reducing sugar values during storage. Tubers of Chippewa sprouted readily, however, and soon became too soft for potato chip manufacture. Irish Cobbler proved satisfactory if storage was delayed until the late starting date, as tubers could then be held at 7° for at least 180 days without undue accumulation of reducing sugar. Tubers of Eureka, Green Mountain, Delaware, Bliss Triumph, Pride of Multnomah, Spaulding Rose, Blue Mercer, Warba, and Axtell Bugless attained high amounts of reducing sugars and were unsuitable for potato chip manufacture on account of the dark color of chips caused by this high sugar content. Sucrose values showed smaller differences than did the reducing sugar values upon storage at the three different temperatures. The order of varieties for increasing amounts of reducing sugar was not at all the order for increasing amounts of sucrose. "Tubers grown under different soil conditions with respect to added fertilizers and tubers of the same variety grown in two different localities showed no important differences in the amounts of reducing sugar developed during cold storage."

Effect of blanching on dehydrated vegetables, J. SUGIHARA, S. T. TSU, and W. V. CREUSS. (Univ. Calif.). (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 21 (1941), No. 4, pp. 104-106, fig. 1).—Peas, beets, turnips, sweetpotatoes, cauliflower, and string beans were blanched for various lengths of time in water at different temperatures and in live steam and dehydrated at 140°-145° F. to a moisture content of 5 percent or less. Tests within a few weeks after dehydration showed that in nearly all cases the blanched products gave greater regains in weight with soaking and greater cooked weights than did the untreated products. In cooking tests with these and other dehydrated vegetables, the steam-blanched products were found superior in flavor and odor to those blanched in hot water. In most cases steam blanching to practically precook the vegetable (5-20 min.) was desirable, since this treatment gave a product that could be readily refreshed and quickly cooked.

Kind and variety of fruits and vegetables important in freezing (*South Dakota Sta. Rpt. 1941, p. 71*).—A progress report of work by M. Kellogg and E. M. Pierson with varieties adaptable to growing conditions in South Dakota.

Further studies on the retardation of the staling of bread by freezing, W. H. CATHCART (*Cereal Chem.*, 18 (1941), No. 6, pp. 771-777, fig. 1).—In a previous study (E. S. R., 82, p. 698) it was observed that bread frozen by sharp freezing methods developed an "off" aroma after about 40 days' storage at -22° or -35°C. To investigate the cause of this off aroma and to increase the length of time that the frozen bread could be kept fresh and salable several methods were employed. These included (1) quicker freezing, (2) variations in the bread formula by successive omission of one of the ingredients and by the use

of oat flour (in the formula or on the wrapping paper) as an antioxidant, and (3) hermetically sealing in the normal atmosphere and in vacuum, employing modern canning technic, before freezing.

The quickest freezing method employed, in which the unwrapped bread was frozen in a forced air tunnel at -35° , reduced the bread to a solid state in 60 min., halving the freezing time from that previously obtained but not, however, significantly increasing the keeping time for the bread. None of the variations in the formula lengthened the keeping time according to organoleptic tests, although the use of oat flour effected a slight lengthening of the keeping time according to peroxide values. Baking and subsequent canning prior to freezing greatly increased the keeping time, the breads remaining in good condition and salable up to 345 days; at 565 days there was some decrease in quality, although there was little evidence of the development of the off aroma. These results indicate that the off aroma is due in part to oxidation. It is pointed out that the canning and freezing of bread may prove of value in cases of emergency, although the lengthening of the keeping time is at present of no great importance in commercial production.

Nutritive value of agar and Irish moss, H. W. NILSON and J. W. SCHALLER (*Food Res.*, 6 (1941), No. 5, pp. 461-469).—Male albino rats with an average initial weight of 53 gm. were fed individually for a 10-week period on a control diet supplemented with 5, 10, 20, and 30 percent of prepared agar and 5, 10, and 20 percent of Irish moss refined for food purposes. In general, all the animals grew very well except those receiving the ration containing 20 percent Irish moss. These suffered a 50-percent mortality, and the survivors grew about 30 percent slower than animals of the control group. Rats fed the 20-percent agar diet gained about 20 percent faster than the control animals. Those fed the 10-percent agar diet and the 5- and 10-percent Irish moss diets required about the same amount of food per gram gain in weight as did the control group; more food was required by the other groups. Rats fed the 20- and 30-percent agar diets and the 10- and 20-percent Irish moss diets required significantly more water per gram gain in weight than did the control group. Apparent digestibilities of agar and Irish moss, calculated from intake and excretion (fecal) of nitrogen-free extract, were about 28 and 50 percent, respectively, irrespective of the level included in the diet. There was a statistically significant progressive depression in apparent digestibility of dry matter of the remainder of the diet as the level of agar or Irish moss increased. This depression amounted to about 10 percent with the higher dietary levels of agar and Irish moss.

Low-priced milk and the consumption of dairy products among low-income families, Washington, D. C., 1940, H. K. STIEBELING, S. F. ADELSON, and E. BLAKE (*U. S. Dept. Agr. Cir.* 645 (1942), pp. 28, fig. 1).—The consumption of fluid milk and other dairy products among selected groups of eligible low-income families was investigated during 1-week periods prior to and following the inauguration of the low-priced milk program. Of the families interviewed, 624 identical ones cooperated in both surveys by giving the information requested. In the preprogram period (May and June 1940) these families bought an average of 0.72 qt. of fluid milk per person per week and their consumption of milk in various forms—purchased and free—was equivalent in nonfat milk solids to 1.99 qt. of fluid milk per person per week. At the time of the second interview (October and November 1940) only 321 of the 624 families were participating in the program and of the participants only about one-half bought the maximum quantities allowed; more than one-fourth bought less than 75 percent of their allowance. The participants during the milk program survey were

buying an average of 2.65 qt. of fluid milk per person per week and the non-participants 0.54 qt. Consumption of milk in all forms, including purchased and free products, was equivalent in nonfat milk solids to 3.66 and 1.92 qt. per person per week among participants and nonparticipants, respectively.

On a per capita basis the Negro families bought more fluid milk and consumed somewhat more milk in all forms—purchased and free—than did the white families. The average quantities of milk in all forms, purchased and free, consumed by participating families after the low-priced program went into effect corresponded roughly to the quantities necessary for low-cost adequate diets including other foods wisely chosen for quantity and kind.

The dietary habits of college students, M. S. REYNOLDS, M. A. OHLSON, M. S. PITTMAN, H. MCKAY, M. B. PATTON, E. DONELSON, R. LEVERTON, E. J. MEILLER, and M. H. BITTING. (Wis., Ohio, Iowa, Kans., Minn., and Nebr. Stas.). (*Jour. Home Econ.*, 34 (1942), No. 6, pp. 379-384, fig. 1).—This is a report of an extensive survey made in 1936-40 as a part of the regional project of the North Central States relating to the nutritional status of college women. A total of 3,432 students distributed in the six cooperating institutions participated by keeping a 7-day record of the kinds and amounts in servings of food eaten.

Analysis of the records showed that meat was chosen most frequently by the largest number of students, while whole-grain products were least often selected. Next in popularity to meat was milk, followed by the green and yellow vegetables and the citrus fruit group. Only small differences appeared between freshmen and upperclassmen with regard to consumption of citrus fruits, whole grains, and meat, but about 18 percent more of the upper-class students reported the consumption of a green or yellow vegetable and of tea, coffee, or cola drinks on the average of once a day. The percentage of students consuming at least one cup of milk a day was 88 in the light-housekeeping group, 84 in residence halls, and 76 in homes and in cafeterias; for green and yellow vegetables, the percentages having at least one serving daily were 82 in organized groups and 66 in homes and in cafeterias. Daily consumption of citrus fruits (and also tomatoes) and whole-grain products was highest in light-housekeeping groups (64 and 66 percent, respectively) and lowest in the residence halls (23 and 32 percent, respectively). In residence halls 97 percent of the students had meat at least once a day, while in the light-housekeeping group only 77 percent of the students had meat daily.

Dietary requirements for fertility and lactation, XXVIII, XXIX, B. SURE. (Ark. Expt. Sta.). (*Jour. Nutr.*, 22 (1941), No. 5, pp. 491-498, 499-514).—In continuation of the series (E. S. R., 84, p. 420), two papers are presented.

XXVIII. *The lactation-promoting properties of cystine when added to casein diets.*—The original purpose of the studies here reported was to determine the lactation-promoting properties of various fats and oils, saturated and unsaturated, when fed at a 15-percent level with two types of salt mixture. The protein of the ration consisted of 17.7 percent of purified casein and 3.7 percent of protein in the dehydrated bakers' yeast used as a source of the B complex. Complete failure of these diets to meet the demands of lactation led to the discovery, based on reports of Daggs and coworkers (E. S. R., 80, p. 708), that cystine is a limiting factor. Fortification of the rations with 0.2 percent of cystine or administration of from 20 to 40 mg. of cystine daily to the lactating mothers resulted in successful lactation and weaning of the young. It is pointed out that these results "do not necessarily prove the essential nature of cystine, but do show that the lactation-promoting properties of a diet containing about 18 percent casein are markedly improved by the addition of this amino acid. Since casein contains

3.0 to 3.3 percent methionine, the rations provided about 0.6 percent of this amino acid, but apparently this amount is insufficient for rearing of young and supplementary cystine can meet the need for successful lactation."

XXIX. *The existence of a new dietary factor essential for lactation.*—On diets in which the vitamin B complex was supplied by pure thiamin, riboflavin, pyridoxin, choline, pantothenic acid, nicotinic acid, and the W factor from liver extracts in generous amounts, albino rats showed excellent growth but reproduction and lactation were abnormal. The use of a new salt mixture designated as Sure's salts No. 1, a modification of the one described by Phillips and Hart (*E. S. R.*, 75, p. 730), resulted in improvement in reproduction but failure in lactation. A rice-bran extract or a liver extract in amounts of 1 gm. daily, beginning at the time of breeding, resulted in successful lactation. On ashing the material negative results were obtained, showing that the factor was organic. Preliminary tests suggested that *p*-aminobenzoic acid and inositol may be components of the essential factor.

The influence of prenatal diet on the mother and child, J. H. FERRIS, F. F. TISDALL, and W. A. SCOTT (*Jour. Nutr.*, 22 (1941), No. 5, pp. 515-526).—Among women less than 6 mo. pregnant who were to be confined in the Toronto General Hospital, 400 with low incomes were studied through the prenatal period, and delivery, with observations on 250 of the babies to the age of 6 mo. After preliminary dietary records had been obtained, the subjects were placed in three groups, the members of one of which received their habitually poor diet without supplements, of another their poor diet supplemented to make up for its deficiencies, and a third a good diet obtained through instruction of the subjects with sufficient means to purchase such a diet.

"During the whole course of pregnancy the mothers on good or supplemented diet enjoyed better health, had fewer complications, and proved to be better obstetrical risks than those left on poor prenatal diets. The incidence of miscarriages, stillbirths, and premature births in the women on poor diets was much increased. The incidence of illness in the babies up to the age of 6 mo. and the number of deaths resulting from these illnesses were many times greater in the poor diet group."

The influence of previous regimes of protein feeding on the endogenous nitrogen metabolism of rats, R. B. FRENCH, J. I. ROUTH, and H. A. MATTELL, (*Jour. Nutr.*, 22 (1941), No. 4, pp. 383-389, fig. 1).—A chart is presented showing the average course of urinary nitrogen excretion (in milligrams per 100 gm. body weight) of young, adolescent, and mature rats placed on a nitrogen-poor diet following previous regimes with various levels of nitrogen intake. In young rats the course of endogenous nitrogen excretion was related to the previous dietary N, rats taken from the stock diet, for example, attaining a constant nitrogen output by the eighth day, while those taken from a high-protein diet had not attained a constant level even after 12 days. With older animals that had been subjected to repeated low-protein or nonprotein regimes interspersed with periods of realimentation, there was an overcompensation for the loss of body protein in these periods and an accumulation of unusual stores. As compared with controls such animals required a longer time on a low-protein diet before their urinary nitrogen fell to an acceptable endogenous level, and there was also a greater loss in body weight. This was particularly noted in maturing animals (100-200 gm. in weight) commonly used for such studies. With such animals, the use of short nonprotein feeding periods would lead to erroneous figures for the biological value of proteins. "Many of the studies on biological value may have been complicated by this unforeseen departure from the ordinary course of endogenous nitrogen excretion."

A study of the biological specificity of inositol, D. W. WOOLLEY (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 461-466).—Several compounds closely related to inositol were tested for their activity as curative agents for alopecia in mice (E. S. R., 86, p. 714) and for their effect on yeast as determined by the method noted on page 476. Of the substances tested, *d*-inositol, *l*-inositol, pinilitol, quebrachitol, and quercitol were inactive for both species; inositol hexacetate, phytin, and soybean cephalin effective for mice but not for yeast; mytilitol was active for mice and about 10 percent as active as inositol for yeast; and the mono- and tetraphosphates of inositol were 5 and 2 percent, respectively, as potent for yeast as inositol. These results are thought to indicate that only those compounds which can readily form inositol are active, while the naturally occurring isomers and those related compounds derived from inositol by substituting one or two hydrogen or hydroxyl groups with other radicals are inactive.

A study of the metabolism of ingested pectin, S. C. WERCH and A. C. IVY (*Amer. Jour. Diseases Children*, 62 (1941), No. 3, pp. 499-511, fig. 1).—In this extension of earlier studies (E. S. R., 87, p. 142), six male medical students served as subjects in an examination of the urine for galacturonic acid and both urine and feces for volatile fatty acids, particularly formic, during the third and fourth day of 4-day periods in which 30 gm. of pectin in gelatin capsules was added to a basal diet low in crude fiber.

In comparison with similar tests before the ingestion of pectin, the results showed no significant increase in the fecal and urinary excretion of volatile acids, particularly formic and acetic acids, and no galacturonic acid in the urine. "Hence, the favorable effects of a diet containing apple or pectin in the treatment of diarrhea cannot be ascribed to an improvement of the detoxicatory function of the liver as a result of the absorption of galacturonic acid. The favorable effects, according to our evidence, are exerted exogenously in the lumen of the bowel."

Phytic acid and the preparation of food, E. M. WIDDOWSON (*Nature [London]*, 148 (1941), No. 3747, pp. 219-220).—This brief report presents evidence to show that phytic acid in wheat suffers some destruction in cooking, due to the action of the enzyme phytase distributed in the flours. White flour, national wheat meal, and wheat meal, representing 70, 85, and 92 percent extraction, respectively, and containing 51, 127, and 214 mg. of phytic acid per 100 gm., showed 85, 69, and 31 percent reduction, respectively, in the phytic acid content when baked as yeast bread. Due to the difference in temperature and in pH, the reductions were much less when baking powder was used in place of the yeast; reductions were greater in products made of white flour with added sodium phytate than in products made of the phytic acid-rich wheat meals. This action of phytase would serve to lessen the extent to which phytic acid interferes with the absorption of calcium in human nutrition.

Low mineral diets and intestinal stasis, E. C. ROBERTSON (*Univ. Toronto Studies, Pathol. Ser.*, No. 9 (1938), pp. 76, figs. 15).—Evidence is presented at length to show that intestinal stasis developed in rats fed a diet very low but not absolutely deficient in minerals and otherwise adequate. These animals showed poorer absorption of water and protein than did controls on an entirely adequate diet. With increase in the K intake above that obtained from the mineral-deficient diet, the severity of the stasis was somewhat lessened, while with increase in Ca alone there was little stasis and with increase in Ca and K there was practically none. These results and others from trials with rats on diets deficient in Ca or K or both minerals showed that a low intake of Ca was necessary in rats for the production of intestinal stasis, while the effect of K was slight and evident only when the intake of all other minerals was low.

On the mineral-deficient diet or one from which Ca or Ca and K were omitted, the pH of the large intestine was about 6.0. Ca seemed to be the essential factor in keeping the pH about 7. Apprehensiveness, excitability, proptosis, polycythemia, dilatation of the lower intestine, and fast heart rates were observed in rats on the low-mineral diet. Since these are conditions occurring when the autonomic nervous system is stimulated, it is suggested that an imbalance in this system can be induced by means of diet alone.

In a group of 19 children receiving a diet furnishing only 0.2 gm. of Ca and 1.0 gm. of K, but otherwise adequate, 74 percent of them became definitely constipated, and after a barium meal 33 percent of them retained the barium in their appendixes for abnormally long periods. The same children fed the same diet adequately supplemented with Ca and K did not retain the barium in their appendixes more than 24 hr. "This suggests that a deficiency of the minerals, especially of Ca, may be one factor in the etiology of constipation and possibly in that of appendicitis."

Bone fractures due to low calcium diets, R. F. LIGHT and C. N. FREY (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 256-258, fig. 1).—Four litters of rabbits were divided at weaning into two groups, one of which was placed on a diet low in Ca (0.199 percent) but adequate in P (0.513 percent) and vitamin D (6.5 U. S. P. units per gram of ration), while the other half received this basal ration plus 1 percent of CaCO_3 . Eight of the nine animals from the former group died suddenly in from 3 to 8 weeks. Autopsy findings showed that one or more vertebrae had been fractured and collapsed in each instance, suggesting that vertebral fractures caused death in all cases. The control litter mates fed the basal diet plus the CaCO_3 showed no signs of paralysis throughout the experimental period, and X-rays showed well-developed normal vertebral columns. These results are considered to suggest that the paralysis observed by Boelter and Greenberg (*E. S. R.*, 86, p. 866) in their studies with rats on low-calcium rations was due to vertebral fractures and resulting compression of the spinal cord. Low-calcium intake is offered as an explanation of the cause of spontaneous vertebral fractures occurring in man.

The effect of calcium and phosphorus retention on nitrogen retention and vice versa, S. C. CHEN (*Chin. Jour. Physiol.*, 16 (1941), No. 3, pp. 303-307).—A study was made of the calcium, phosphorus, and nitrogen metabolism of young rats on diets containing about 12 percent of protein furnished as equal amounts of egg albumen and casein or as wheat gluten. Each of the two protein diets was fed at two levels of calcium intake, 0.1 and 0.4 percent, with the respective levels of phosphorus intake at 0.2 and 0.8 percent. At both levels of calcium and phosphorus intake the biological value of egg albumen plus casein was 86, indicating no influence on the biological value of a protein of good quality. The biological value of the gluten was 71 at the higher level of calcium and phosphorus intake and 65 at the lower level, suggesting a slightly favorable influence of calcium and phosphorus retention on protein retention. The percentage of calcium retention was not influenced by the quality of the protein, but the percentage of phosphorus retention was favorably influenced by a higher nitrogen retention.

Relation of calcium, phosphorus, and nitrogen retention to growth and osseous development, A. L. DANIELS (*Amer. Jour. Diseases Children*, 62 (1941), No. 2, pp. 279-294, figs. 3).—Retentions of calcium, phosphorus, and nitrogen, gains in height and weight, and changes in bone development as shown by roentgenograms of the hands and wristbones were followed in three preschool boys over a 9-mo. period. Although the boys were apparently well-nourished, the first roentgenograms indicated that they were skeletally retarded, with

skeletal ages from 6 mo. to 1 yr. 11 mo. below the chronological ages (Todd standard.) The diets fed throughout the study furnished from 53 to 76 mg. of Ca per kilogram of body weight per day, with from 75 to 78 percent supplied by a daily intake of 750 gm. of milk; from 56 to 81 mg. of P per kilogram; and 3.4 gm. of protein per kilogram daily during the first 7 mo. of the study and 2.6 gm. per kilogram during the last 2 mo. Milk, eggs, and meat furnished 80 percent of the protein. Skeletal ages were determined by four standards—those of Flory, Todd, and the fiftieth and ninetieth Harvard percentiles.

Calcium retentions over the several balance periods averaged 10.9, 10.0, and 11.3 mg. per kilogram for the three boys, respectively; phosphorus retentions 8.7, 8.2, and 7.9; and nitrogen retentions 57, 56, and 46 mg. per kilogram. These retentions, high at the beginning of the study, remained high and in some cases were even higher in the end periods than in the early periods. Decrease in the nitrogen ingestion did not influence nitrogen retention, indicating that the 2.6 gm. of protein per kilogram was sufficient for the average child of preschool age. The higher retentions were associated with gains in height in two cases and in weight in two cases and occurred during April, May, and June, when more time was spent out of doors. Over the period of the study the skeletal ages of the children tended to approach the normal by all standards.

The author had the technical assistance of G. J. Everson, M. F. Deardorff, O. E. Wright, and F. L. Scoular.

Magnesium needs of preschool children, A. L. DANIELS (*Amer. Jour. Diseases Children*, 62 (1941), No. 3, pp. 568-576).—This second report on the magnesium needs of children (*E. S. R.*, 76, p. 883) represents part of the study (noted above) of the growth, osseous development, and mineral metabolism of three preschool boys. Each metabolism period consisted of two consecutive 5-day balance periods preceded by a 6-day adjustment period, and in the course of the study the magnesium intakes, which came from the food alone, represented three different levels. As far as possible calcium ingestions were kept constant throughout the study. With magnesium ingestion between 11.8 and 14.5 mg. per kilogram of body weight, average retentions for the three boys were almost constant (from 0.9 to 1.3 mg. per kilogram), although there was considerable variation from period to period. With lower ingestions, between 10.4 and 11.4 mg. per kilogram, retentions varied between just positive and frankly negative. It is concluded, therefore, that 11.8 mg. per kilogram is the minimal amount that should be included in the diet of the child of preschool age, but that this level would not provide any appreciable margin of safety. Percentages of ingested magnesium excreted in the feces were consistent at all levels of intake, averaging between 63 and 71 percent. "The average calcium: magnesium retention ratios during periods of positive calcium and magnesium retention were fairly constant; retentions during individual balance periods, however, varied widely, and although the retention ratio of the averages corresponded to the calcium: magnesium ratios of rapidly growing tissues (human fetuses), there was not sufficient evidence to conclude that these two substances are metabolically dependent on each other." The author had the technical assistance of G. J. Everson and M. L. Cooper.

Magnesium balance studies with infants, C. F. SHUKERS, E. M. KNOTT, and F. W. SCHLUTZ (*Jour. Nutr.*, 22 (1941), No. 1, pp. 53-64, figs. 2).—Nine male infants less than 6 mo. old., and receiving milk formulas to which either corn sirup or honey was added with vitamin and mineral supplements, were studied for at least eight 5-day metabolism periods (separated by periods of from 3 to 7 days) in which total magnesium intake varied from 54.6 to 245.3 mg. per day with fecal losses and urinary excretion amounting to from 39.5 to 191.6 mg. and from 1.0

to 21.6 mg. per day, respectively. Retentions were similarly variable within the limits of -23.5 and 105.9 mg. per day. In 33 of the periods at levels of intake under 20 mg. per kilogram per day, the retentions averaged 1.42 mg. per kilogram, whereas in 44 periods with intakes between 20 and 35 mg. per kilogram per day the mean retention was 3.96 mg. per kilogram. Fecal excretion of the magnesium averaged about 80 percent of the intake, exceeding it in 6 periods and being less than 60 percent of it in only 9 periods. Urinary excretion of magnesium varied from 1.0 to 21.6 mg., with a mean of 10.5 mg. per day. Both fecal and urinary losses tended to vary with the intake, although there were numerous exceptions. No definite relationship was noted between (1) magnesium and calcium retentions, (2) fecal phosphorus excretion and magnesium content of the feces or magnesium retention, and (3) the level of vitamin D (0-1,000 International Units daily) and the magnitude of magnesium retention. Slightly better retentions were found with honey than with corn sirup, although the data were not conclusive, and variations with different types of milk were ascribed to the level of magnesium intake.

Manganese and the growth of lactic acid bacteria, D. W. WOOLLEY (*Jour. Biol. Chem.*, 140 (1941), No. 1. pp. 311-312).—Observations that certain natural products produced much more rapid growth of *Lactobacillus casei* than did optimal amounts of pantothenic acid led to an investigation to determine the nature of this growth factor not supplied by the basal medium. Malt sprouts, or an aqueous extract from them, served as the best source of the growth factor, which was found to be carried over into the ash and to have its activity destroyed by H₂S. "Trials of several metallic salts showed that manganese was the effective material. Salts of Cu, Pb, As, Sb, Sn, Hg, Bi, Cd, Tl, Fe, Zn, W, and Mo. (0.01γ to 100γ) were without effect or were inhibitory. . . . The effect of manganese was only upon the rate of growth and not on the extent. With manganese, growth and acid production were complete in 12 to 16 hr.; without it approximately 40 hours' incubation was required." *Escherichia coli* and hemolytic streptococci of groups A and D were not affected by manganese.

Histological studies of the tissues of rats fed a diet extremely low in zinc, R. H. FOLLIS, JR., H. G. DAY, and E. V. MCCOLLUM (*Jour. Nutr.*, 22 (1941), No. 3, pp. 223-237, pls. 2).—The present report deals with the pathological changes observed in rats on a diet extremely low in zinc content but adequate in other respects. The diet, previously described (E. S. R., 86, p. 273), furnished not more than 2-4 μg. of zinc per rat per day. Mothers of the two litters of test animals were restricted to the zinc-deficient diet when the young were 12 days old. Control animals taken at about 25 days of age and given this diet with zinc supplementation to the extent of 0.15 mg. of zinc per animal per day were normal with respect to growth, appearance, histology, and reproductive behavior. Growth in zinc-deficient rats became retarded after the first 2 or 3 weeks, the hair became sparser after from 3 to 5 weeks, and subcutaneous fat disappeared. After about 70 days alopecia accompanied by roughened, scaly skin developed in some of the animals. Microscopic examination of stained sections of various tissues indicated specific pathological changes in the esophagus of deficient animals and to a lesser extent changes in the buccal cavity and the skin, and, in a few animals, in the cornea. "The esophagus showed extreme parakeratosis with a thick layer of partially keratinized cells. The skin showed hyperkeratinization, thickening of the epidermis, and loss of hair follicles with persistence of the sebaceous glands. Secondary bacterial infection occurred later. The cornea of two animals showed vascularization and leucocytic infiltration similar to that which has been described in riboflavin

deficiency. These ocular changes may indicate that zinc deficiency impairs the absorption or utilization of riboflavin."

Iodine in nutrition (*New York: Iodine Ed. Bur., Inc., [1941], pp. [250]*).—A bibliography issued in loose-leaf, mimeographed form. The compilation is kept up to date with current supplements.

Reduction in experimental rat caries by fluorine, S. B. FINN and H. C. HODGE (*Jour. Nutr.*, 22 (1941), No. 3, pp. 255-266, figs. 6).—One hundred and thirty-five rats were divided into three groups at weaning, the groups being given, respectively, a cracked corn caries-producing diet, this diet with the substitution of commercial casein for the powdered whole milk, and the latter diet with the daily addition of 3 mg. of fluorine administered by pipette as a solution of KF. After 200 days on the diets, the animals were sacrificed and the jaws were examined for caries and fractures. Further examination involving repeated successive grinding and staining of teeth from the right jaw and preparation of ground, decalcified, stained sections of teeth from the left jaw gave evidence, respectively, as to the grades of fissure caries and the nature and progress of fissure lesions. The findings (tabulated), examined for statistical significance and discussed, indicated that there was little, if any, qualitative difference in the appearance of the fractures in the teeth of the fluorine-fed group as compared with the controls, and that all rats exhibited many fractured cusps. However, the rates fed fluorine developed only about half as many cavities, and these of smaller size, as compared with the controls not fed fluorine (1.1 and 3.5 cavities per rat, respectively). Thus, for each cusp involved in the fluorine group, there were 3.6 cusps involved in the casein-fed controls. Moreover, for each tooth destroyed in the fluorine-fed group, 4.2 teeth of the controls were destroyed. "The data given above lead to the hypothesis (1) that fluorine prevents the development of a carious lesion on the site of a fractured cusp, thus giving the caries-free mouths; and (2) that fluorine prevents the development of a small cavity into a larger one, thus giving the lesser number of cusps involved and whole teeth destroyed."

Effect of various dietary deficiencies on the periodontal tissues of the guinea-pig and of man, P. E. BOYLE (*Jour. Amer. Dent. Assoc.*, 28 (1941), No. 11, pp. 1788-1793, figs. 7).—In this address the effects of prolonged deficiencies of vitamins A, C, and D on the teeth and periodontal tissues are differentiated.

Photodynamic action and diseases caused by light, H. F. BLUM (*New York: Reinhold Pub. Corp., 1941, pp. XII+309, figs. 50*).—This book, covering an extensive literature, reviews the evidence and points of view presented by the different workers in the field, and relates material under the various phases to draw conclusions where possible or present hypotheses where the material is uncertain or fragmentary. Discussion of the various phases of photobiology is preceded by brief chapters on light and photochemistry treated in terms of the quantum concept. Photodynamic action and diseases produced by light in domestic animals and in man are discussed. It is pointed out that there are many laboratory examples of photodynamic action, but that authentic examples in nature are relatively few, although of considerable importance. Hypericium (St. Johnswort poisoning or Klamath disease), geeldikkop (yellow thickhead), and fagopyrism (buckwheat poisoning) in sheep are examples of such photodynamic action.

Consideration is given to abnormal sensitivity to light in man, the response of normal skin to light and the sunburn spectrum, abnormal sensitivity to the sunburn spectrum, abnormal response to blue and violet light, the photosensitizing action of porphyrins in man, effects of long exposure to sunlight and skin

cancer, photosensitization by substances coming into contact with the skin or applied internally, and other diseases attributed to the action of light, including the bronzing of the skin in pellagra.

Dark adaptation: Some physiologic and clinical considerations, J. MANDELBAUM (*Arch. Ophthalmol.*, 26 (1941), No. 2, pp. 203-239, figs. 9).—This paper discusses in considerable detail the measurement of dark adaptation; the physiology of dark adaptation; and clinical applications of the measurement of dark adaptation in vitamin A deficiency, retinitis pigmentosa, and glaucoma. The section on vitamin A deficiency includes a discussion of the interpretation of dark adaptation curves as indicating the state of vitamin A nutrition, the variability in response of individual subjects to a vitamin A-deficient diet and in recovery from a state of vitamin A deficiency, and disturbances in dark adaptation caused by diseases of metabolic origin.

Cure of spectacle eye condition in rats with biotin concentrates, E. NIELSEN and C. A. ELVEHJEM. (*Wis. Expt. Sta. et al.*). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 349-352).—Evidence that the spectacle eye condition in rats described by various investigators is due to biotin deficiency is presented in detail and summarized as follows:

"The spectacle eye syndrome in rats has been produced very consistently by the inclusion of egg white in a synthetic diet which allows good growth in the absence of egg white. Pantothenic acid at levels up to 100 γ per day does not prevent the onset of this condition. Corn oil and pyridoxin or the combination of the two are without effect. Inositol has neither a preventative nor a curative action under these conditions. A biotin concentrate at a level of 2 γ of biotin per day is specific for the prevention and cure of this syndrome. The cure is first noticeable after 5 days, and complete restoration of the hair results after 2-3 weeks of treatment. A definite weight gain is noted with rats receiving the biotin concentrates."

The influence of chronic vitamin-A deficiency on the bacterial flora of rats, C. G. BURN, A. U. ORTEN, and A. H. SMITH (*Yale Jour. Biol. and Med.*, 14 (1941), No. 1, pp. 89-99).—This paper reports a comparison of the bacteriological findings in the mucosal surfaces and viscera of rats in a state of chronic vitamin A deficiency, controls with complete vitamin A deficiency, and normal controls.

During the year of observation, the rats in the chronic A deficiency group showed a progressive increase in the number of bacteria in the mucous membranes and tissues examined, and at the end of the year the findings were indistinguishable from those of acute vitamin A deficiency. In both chronic and acute deficiency there was a shift in the bacterial flora from a variety of organisms, few in number, to many colonies, chiefly *Staphylococcus aureus* and *Pseudomonas fluorescens*. In the animals with acute deficiency there was in addition a marked decrease in *Bacterium coli* in the intestinal flora.

One of the important differences between the animals in chronic and acute vitamin A deficiency was the absence in the former of widespread suppuration of the tissues. The minute quantities of vitamin A fed daily to this group not only controlled the infection, but prevented widespread distribution of the lesions. The staphylococcus was considered to be the organism of greatest etiological importance, with the other organisms as secondary invaders. However, none of the organs in which the organism was found showed gross or microscopic evidence of suppuration. The resistance induced by vitamin A is thought to be the result not of specific action on the toxic or on the invasive properties of the bacteria, but of nonspecific stimulation, the nature of which is not yet known.

Changes in the structure of the developing tooth in rats maintained on a diet deficient in vitamin A. C. G. BURN, A. U. ORTEN, and A. M. SMITH (*Yale Jour. Biol. and Med.*, 13 (1941), No. 6, pp. 817-830, pls. 3).—Essentially noted from a preliminary report (E. S. R., 78, p. 282).

Vitamins in dermatology (*Rahway, N. J.: Merck & Co., 1942, pp. [2]+55*).—Under date of March 1942, each of the known vitamins is reviewed as to physical and chemical properties, history, general and skin manifestations, and preventive and therapeutic dosage. Chapters are also included on unsaturated fatty acids, amino acids, and nomenclature. A bibliography of 191 titles is appended.

Seborrhoea and the B vitamins (*Brit. Med. Jour.*, No. 4203 (1941), pp. 124-125).—This editorial review, based chiefly on the work of György and associates, emphasizes the gross resemblance between the lesions of seborrhea in man and the scaly desquamations experimentally produced in the rat from a deficiency of pyridoxin, pantothenic acid, and riboflavin and by egg white injury. The view that excess of any of the three food constituents fat, protein, and carbohydrates has a causative relation to seborrhea is considered compatible with deficiencies of the above B vitamins as causal factors through the evidence of the interrelationship between proteins and biotin, fats and pyridoxin, and carbohydrates and riboflavin. It is suggested that "the relation of these various vitamins to seborrhea in man will have to be worked out by the controlled therapeutic administration of prepared concentrates or synthetic substitutes."

The pantothenic acid content of the blood of Mammalia. P. B. PEARSON. (Tex. Expt. Sta.). (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 423-426).—The bacteriological method with the medium and organism described by Pennington et al. (E. S. R., 85, p. 442) was used in this study of the pantothenic acid content of whole blood, plasma, and cells of from 10 to 13 representatives of six animal species. Both sexes were used except in the human studies where the subjects were males. Except for rabbits, all of the subjects were adult. For whole blood the lowest average value, 19 ± 3.7 $\mu\text{g.}$ per 100 cc., was obtained with the human subjects, followed in increasing order by the dog, sheep, pig, horse, and young rabbit with a value of 71.7 ± 16.5 $\mu\text{g.}$ per 100 cc. For the plasma the lowest reading was again with the human subjects with a value of 17.0 ± 3.3 $\mu\text{g.}$ per 100 cc., followed by the other species in the order sheep, dog, pig, horse, and rabbit with a value of 57.8 ± 15.8 $\mu\text{g.}$ per 100 cc. In the horse, human being, rabbit, and sheep the content of pantothenic acid in the cells was greater than in the plasma, while in the other species the reverse was true. The value obtained for human cells was 23.6 ± 6.1 $\mu\text{g.}$ per 100 cc. Approximately 44 percent of the total pantothenic acid of the blood of the human subjects occurred in the plasma, while in the other species the amounts ranged from approximately 59 to 63 percent.

Relation of water metabolism to porphyrin incrustations in pantothenic acid-deficient rats. F. H. J. FIGGE and W. B. ATKINSON (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 112-114).—By controlling the water intake of rats on an unlimited, presumably adequate, stock diet, the authors have demonstrated that porphyrin incrustations on the nose and fur, identical with those which have been considered to be the most conspicuous sign of pantothenic acid deficiency, may be produced in normal rats by partial dehydration. This is thought to indicate that pantothenic acid may be involved in the regulation of water metabolism.

Rôle of para-aminobenzoic acid in vitamin B-complex studies with mice. G. J. MARTIN and S. ANSBACHER (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 118-120).—When a group of 75 black mice was fed a basal diet supple-

mented daily with several sources of the B complex vitamins—thiamin hydrochloride 25 μ g., riboflavin 50, pyridoxin hydrochloride 25, nicotinic acid 500, choline chloride 1,000, calcium pantothenate 250, and inositol 500 μ g.—75 percent of the animals showed graying of the fur in from 2 to 4 weeks, while in another group of the same number receiving as further supplement 250 μ g. daily of *p*-aminobenzoic acid the fur remained black during the 9-week test period. The omission of calcium pantothenate from the same diet for another group of 75 led to the development of signs of pantothenic acid deficiency in about 80 percent of the animals, and the omission of inositol alone to the development of typical alopecia in about 80 percent. When both inositol and *p*-aminobenzoic acid were omitted, alopecia did not develop. The authors conclude that "*p*-aminobenzoic acid has anti-gray hair activity in the nutritional achromotrichia of the mouse. It is a dietary factor necessary for the demonstration of the anti-alopecia effect of inositol."

Effect of adding vitamin B complex to the diets of stabilized diabetic children. R. L. JACKSON and I. BARTH (*Amer. Jour. Diseases Children*, 62 (1941), No. 3, pp. 516–520, figs. 2).—Five diabetic children under good control as to insulin requirement, freedom from glycosuria and clinically significant insulin shock, and normal diurnal blood sugar fluctuations from day to day were given for periods averaging 25 days 2 or 3 mg. daily of thiamin in vitamin B complex in addition to their regular controlled diet calculated to furnish from 1.07 to 1.8 mg. of thiamin daily. Two of the subjects were observed for another period, averaging 2 weeks, during which the supplement was not given. The blood sugar curves showed no significant change as a result of the additional amounts of vitamin B complex, thus indicating that the insulin requirement of diabetic children is not lessened by the consumption of vitamin B complex in amounts in excess of those obtainable in well-planned diets.

Studies in nicotine acid metabolism, I, II (*Jour. Nutr.*, 23 (1942), No. 1, pp. 23–45).—Two papers are presented.

I. *The fate of nicotinic acid in man*, H. P. Sarett, J. W. Huff, and W. A. Perlzweig (pp. 23–34).—In this study of the fate of nicotine acid in normal man under controlled dietary conditions before and after the administration of nicotinic acid derivatives, three series of experiments were run. (1) Three normal individuals were maintained on a control diet of trigonelline-free foods, and the levels of daily excretion of the acid hydrolyzable nicotinic acid fraction (NA) and trigonelline were determined by a slight modification (described in detail) of the method noted previously (*E. S. R.*, 86, p. 712) before and after test doses of nicotinic acid administered orally; (2) the urines of 33 medical students on various diets low in trigonelline and of 3 students who had fasted for 3 days were analyzed for NA and trigonelline; and (3) 6 normal young adults were given saturation tests with nicotinamide.

In (1) the excretion of trigonelline on the control diet free from sources of trigonelline ranged from 9 to 13 mg. daily and of NA from 1.1 to 1.5 mg. The trigonelline values were substantiated by values of from 8 to 12.6 mg. daily excreted by the 3 fasting individuals. Following test doses of 200 mg. of nicotinic acid taken on the third day, the added excretion of NA and trigonelline by the 36 subjects amounted during the 2-day period to 44 mg. of which from 55 to 84 percent was in the form of trigonelline and the remaining 16–45 percent nicotinic acid. The added excretion amounted to from 17 to 22 percent of the ingested dose. Of 200 mg. of nicotinamide taken on the ninth day, from 18 to 30 percent could be accounted for by the increased trigonelline excretion in the following 2 days, and there was no increase in NA fraction. Trigonelline ingested in 200-mg. doses was excreted to the extent of from 80 to 90 percent

and nicotinuric acid in 100-mg. doses to the extent of 56, 60, and 65 percent, with no increase in trigonelline. In (2) the daily excretion of NA ranged from 0.7 to 2.2 mg. and was not affected by smoking. In (3) the urinary excretion of NA and trigonelline by 6 subjects after six daily doses of 500 mg. accounted for from 27 to 42 percent of the ingested doses, with over 90 percent of the added excretion in the form of trigonelline. The authors conclude that "the extra excretion of NA and trigonelline after a test dose of nicotinamide may serve as an indication for the nutritional status of an individual with respect to nicotinic acid."

II. *The fate of nicotinic acid in normal and black tongue dogs*, H. P. Saret (pp. 35-45).—Studies similar to the above for man are reported for dogs, with essentially the same results. Trigonelline and nicotinuric acid were the end products of nicotinic acid metabolism in the dog's urine. The excretion of trigonelline fell to from 1.1 to 2.7 mg. per day on a low nicotinic acid diet and to 0.1 mg. in blacktongue. In both instances several 25-mg. doses of nicotinic acid were required before part of the dose was excreted. On higher nicotinic acid diets a total of about 7 mg. of the 12-15 mg. ingested daily was excreted, 90 percent of which was in the form of trigonelline. After saturation with nicotinic acid, 100-mg. doses were completely excreted in the form of trigonelline (75-94 percent) and nicotinuric acid from 6 to 25 percent.

In part I the authors had the technical assistance of M. Stenhouse and R. Forth, and in part II of Stenhouse.

Environmental temperatures and thiamine requirements, C. A. Mills (*Amer. Jour. Physiol.*, 133 (1941), No. 3, pp. 525-531, figs. 3).—Young rats were kept in separate cages in two rooms of the same relative humidity, 60 percent, but different temperatures, 65° and 91° F., and given identical diets except for a thiamin content which was graded at 0.2, 0.4, 0.6, 0.8, 1.2, and 1.6 mg. per kilogram of food mixture. Detailed records were kept of the food consumption and weight gains.

In the hot room the food consumption of the individual groups was almost quantitatively proportional to the increase in thiamin content of the diet up to 1.2 mg. per kilogram, with a slightly lower consumption at the 1.6-mg. level. The growth rate and growth efficiency (grams of food intake per gram of weight gain) were also highest at the 1.2-mg. level, although the differences were slight in growth between the 1.2- and 1.6-mg. levels. In the cold room only the groups receiving the two lowest proportions of thiamin consumed little food and lost weight. The best performance was given by the group receiving 0.8 mg.

Taking into consideration food consumption, growth rate, and growth efficiency, the optimal response at 91° required about twice as high a dietary content of thiamin as at 65°. The actual quantity of thiamin consumed, however, was about the same, suggesting that on an economic basis it would probably be less expensive to administer thiamin in pure form or with some food universally used than to try to obtain adequate amounts in natural foods. "Only by thorough trial can the protective value of thiamin against excessive heat be established for man. Daily administration of supplemental thiamin should make workers in boiler or furnace rooms, or in other types of severe heat exposure, more resistant to the heat effects. It should also prove helpful for temperate zone residents who are hypersensitive to the heat waves of summer and for those who have developed symptoms of heat exhaustion."

The thiamin content of human blood and urine as determined by the fermentation method, R. GOODHART (*Jour. Clin. Invest.*, 20 (1941), No. 6, pp. 625-630, figs. 4).—The ultramicrofermentation method described by Atkin, Schultz, and Frey (*E. S. R.*, 83, p. 444) was used, with minor modifications.

In 86 determinations on blood samples from 45 presumably normal subjects, the minimum, maximum, and average values obtained were 3.1, 9.2, and 5.39 μg . percent, the values agreeing reasonably well with those calculated from cocarboxylase values reported by Goodhart and Sinclair (E. S. R., 83, p. 420). In 42 determinations of the 24-hr. urine excretion values of 11 normal subjects, corresponding values were 240, 1,327, and 596 μg . The higher urine values obtained by the fermentation method than by most other procedures are attributed to the high content in the urine of 2-methyl-5-hydroxy-methyl-6-aminopyrimidine, shown by Schultz et al. (E. S. R., 79, p. 11) also to stimulate fermentation of glucose by yeast.

Blood thiamin determinations on 106 patients from the wards of a hospital psychiatric division gave values below 3.1 μg . per 100 cc. in 22 cases, of whom 18 were suffering from peripheral neuritis. The association between acute peripheral neuropathy and low blood thiamin values suggests the likelihood that blood thiamin values below 3.0 μg . percent, as determined by the fermentation method, will prove to be a definite indication of a thiamin deficiency state.

The author had the technical assistance of T. Nitzberg.

Blood pyruvate curves following glucose ingestion in normal and thiamine-deficient subjects, E. BUEDING, M. H. STEIN, and H. WORTIS (*Jour. Biol. Chem.*, 140 (1941), No. 3, pp. 697-703, figs. 2).—Evidence is presented leading to the conclusion that pyruvic acid is a normal intermediary of carbohydrate catabolism in man. In 27 observations on 23 apparently healthy, well-nourished subjects, the ingestion of glucose (1.75 gm. per kilogram body weight as a 25-percent solution in tea) was followed by a significant rise in blood pyruvic acid, as determined by the method described previously (E. S. R., 85, p. 852), with slight modifications. The maximum rise occurred at the end of 60 min. in every case but one, in which the peak was reached in 30 min. A fall to the normal fasting range occurred in all but one instance at or before the third hour. In 13 subjects with thiamin deficiency the maximum rise in pyruvic acid was greater than in the normal subjects and did not reach maximum levels until the end of from 2 to 4 hr.

Sensitization to thiamine hydrochloride, C. L. LAWS (*Jour. Amer. Med. Assoc.*, 117 (1941), No. 3, p. 176).—In the case report presented evidence is given of induced sensitization to thiamin hydrochloride following prolonged subcutaneous administration in doses of 25 mg. or more. The treatment started in September 1940 with daily injections for 10 days, followed by injections at weekly intervals. Sensitization was first noted in February 1941. Two mo. later, when an interval of 10 days had elapsed between tests, the injection produced anaphylactic shock, requiring epinephrine for relief. Intradermal tests demonstrated the allergic effect of the thiamin. The advisability is suggested of making intradermal tests with thiamin hydrochloride before administering it, particularly to patients who previously had received thiamin.

Vitamin deficiencies and flour milling, C. E. RICH (*Chem. and Indus.*, 60 (1941), No. 33, pp. 611-618).—This paper, presented as an address, is concerned with the reasons for milling vitamin B₁ out of the flour and methods of increasing the vitamin B₁ content of bread. In considering what the miller can do about it, it is pointed out that retention of the bran coat and germ would insure an adequate vitamin B₁ supply, but that these portions of the kernel contain substances detrimental to good baking quality so that a balance will have to be struck at some point between nutritive value and baking quality.

Thiamin content of commercial wheats of the 1940 crop, D. E. DOWNS and W. H. CATHCART (*Cereal Chem.*, 18 (1941), No. 6, pp. 796-801).—Data are reported on the thiamin content of 149 samples of wheats from at least 18 States.

The samples, presumably of the 1940 crop, were assayed by the fermentation method of Schultz, Atkin, and Frey (E. S. R., 83, p. 417).

The values found ranged from 4.1 to 10.2 μg . per gram ("as received" moisture basis). There was a wide variation among samples from any State, but in general those States producing hard winter wheat (except Oklahoma) gave thiamin values of 7 μg . per gram or more, while States producing soft red winter or white wheats gave thiamin values of from 5.7 to 6.1 μg . The 8 samples of Dakota spring wheats had an intermediate value of 6.5 μg . The number of pure variety samples grown over a wide area was not sufficient to show any varietal trends. Tenmarq and Turkey samples (hard wheats) were very near the average for the State in which grown. In general the hard wheats, those having a hard, vitreous berry with accompanying higher protein content, had a higher thiamin content, averaging 7.1 μg . per gram, than the softer wheats which averaged 6.1 μg . per gram.

The thiamin content of cereal grains, R. NORDGREN and J. S. ANDREWS (*Cereal Chem.*, 18 (1941), No. 6, pp. 802-811, fig. 1).—Thiamin was determined by the Hennessy and Cerecedo modification of the thiochrome method (E. S. R., 82, p. 588) in wheats of different types and varieties grown in different environments. The data, subjected to statistical analysis, showed that in the 6 varieties of spring wheats grown in four locations in Minnesota environmental factors played a large role in deciding the thiamin content, while variety factors were of much less consequence; and that there was a significant relationship between thiamin and ash but not between thiamin and protein. In the case of 4 varieties of winter wheat, each grown in four regions in Nebraska and Kansas, both variety and environment were highly significant and of similar magnitude, and no significant relation existed between thiamin and ash or between thiamin and iron content. In a series of soft wheats grown in one location in Ohio, 12 of the 15 samples were within 3 percent of the average, 2 were only about 10 percent below average, and 1 was somewhat above average. Since only single samples were represented, the differences were not ascribed to varietal effect. Twelve west coast wheats had an average thiamin content similar to that of the winter wheats grown in Midwestern States. In a series of Canadian wheats the Winnipeg-grown samples, with the exception of one variety, were higher in both thiamin and ash than the corresponding varieties grown in other locations. Despite this, there was no significant relation between the vitamin and ash in either group. It is concluded that the thiamin content of wheat is influenced by wheat type, variety, and environment. In general the durum and spring wheats contained the largest amount of thiamin (from 1.45 to 3.49 mg. per pound), followed by hard winter (from 1.65 to 2.71 mg. per pound), and soft (from 1.79 to 2.38 mg. per pound) wheats. Corn, rye, barley, and sorghum were found similar to wheat in their thiamin contents, while oats contained somewhat more (from 3.68 to 4.90 mg. per pound).

Thiamin in the products of wheat milling and in bread, R. C. SHERWOOD, R. NORDGREN, and J. S. ANDREWS (*Cereal Chem.*, 18 (1941), No. 6, pp. 811-819, figs. 3).—The thiamin content of products of commercial milling was determined in samples taken from three different hard wheat mixes, and from these values and the average values for milling yields the percentage of the total wheat thiamin in each of the milled products was calculated. The calculations indicated that patent, first clear, second clear, and red dog flours, representing, respectively, 63.0, 7.0, 4.5, and 4.0 percent of the cleaned wheat, contained, respectively, 8.0, 3.9, 10.0, and 22.0 percent of the total thiamin of the whole grain; germ, shorts, and bran representing 0.2, 12.3, and 9.0 percent of the milling yield contained, respectively, 0.9, 39.6 and 15.6 percent of the total thiamin of the wheat.

The relatively low proportion of thiamin in the germ is accounted for by the fact that less than 10 percent of the total germ was recovered in the germ stream. Ash values, which reflect the type of milling, were found to parallel closely the thiamin values in the patent, clear, and red dog flours, but in the shorts and bran further increases in ash were associated with marked and irregular decreases in thiamin. This relation between ash and thiamin contents was found to exist not only in the milled products but in millstreams which were obtained from many mills. In the latter the high correlation between ash and thiamin prevailed until the ash content reached about 2.5 percent. Above this value the correlation was less significant because of the varying amounts of outer bran tissues which are low in thiamin. Analyses of the various products and millstreams indicated that the major part of thiamin occurs in the tissues beneath the outer bran, these tissues being responsible for the high thiamin content of the feeds such as red dog and shorts. Commercial whole-wheat flours from 31 mills distributed over the United States averaged 2.27 mg. of thiamin per pound (range 1.92-2.53), and the breads baked from these flours in the laboratory by a commercial formula averaged 1.36 mg. of thiamin per pound of fresh bread.

Vitamin C content of wild fruit products, M. ANDROSS (*Analyst*, 66 (1941), No. 786, pp. 358-362).—The vitamin C content, determined by the procedure of Mack and Tressler (*E. S. R.*, 78, p. 154), is reported for wild rose hips analyzed raw, at the underripe, ripe, and overripe stages, as the dried product, and in the form of several cooked products, including a purée and a jam. The rose hips, containing in the raw state from 370 to 623 mg. of ascorbic acid per 100 gm., and the products made from them are particularly recommended for use in the English diet to take the place of citrus fruits now unavailable. Other fruits, analyzed in the raw state and in the form of several products, including fresh, canned, and bottled juices, jellies, and jams, gave the following values, in milligrams per 100 gm., for the fresh fruits: Sloe 4-8, elderberry 25-30, bramble 2-5, crab apple 10-12, cranberry (syrup) 12-18, raspberry 15-20, bilberry 8-9, and black currant 120-134.

The composition and nutritive value of potatoes, with special emphasis on vitamin C, W. B. ESSELEN, JR., M. E. LYONS, and C. R. FELLERS (*Massachusetts Sta. Bul.* 390 (1942), pp. 19).—This bulletin summarizes published information on the proximate, mineral, and vitamin composition and nutritive value of potatoes, and presents original work on their content of vitamin C. Ascorbic acid determinations were made on a sulfuric-metaphosphoric acid extract by the 2,6-dichlorophenolindophenol titration method as modified by Bessey and King (*E. S. R.*, 71, p. 137) and by Mack and Tressler (*E. S. R.*, 78, p. 154). Dehydroascorbic acid was shown to be absent. Analyses made soon after harvest of five varieties, as grown in Massachusetts and in several other States, showed little variation attributable to geographic factors but suggested varietal differences. In general the Irish Cobbler variety was highest in ascorbic acid, averaging 0.131 mg. per gram, followed in order by Katahdin (0.125), Green Mountain (0.117), Rural Russet (0.110), and Chippewa (0.097 mg per gram). In many cases differences between varieties were less than differences within a single variety. With storage varietal differences became less significant. Tests with eight varieties held for 5 mo. in dry underground storage (40°-50° F.) and in cold storage (36°) showed ascorbic acid losses to vary from 0 to 63 percent, with neither type of storage consistently superior to the other except that tubers held in cold storage were more desirable for eating purposes.

Boiling whole in the skin, baking, and French frying were the best methods from the standpoint of ascorbic acid retention, the cooking losses in these cases amounting to 27, 31, and 33 percent, respectively; losses by other methods

of cooking were appreciably higher, reaching 47 percent in boiled, peeled, halved potatoes, and as high as 79 to 80 percent in warmed-over potatoes and 74 percent in potato salad prepared from boiled potatoes held 24 hr. in the refrigerator. Ascorbic acid was found to be evenly distributed in the raw tuber, with a lesser amount in the skin. After boiling the greater amount was in the area between the central and epidermal portions, with the skin and the part just beneath it about equal in ascorbic acid content; and after baking the greatest concentration was in the central portion, with the amount decreasing progressively toward the skin.

The ascorbic acid content of different varieties of Maine-grown tomatoes and cabbages as influenced by locality, season, and stage of maturity, E. F. MURPHY. (Maine Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 9, pp. 483-502, figs. 6).—Four varieties of tomatoes were grown in 1938 and 1939 in four widely separated localities in Maine to determine the effect of geographical situation upon the production of ascorbic acid. Varietal differences were similar in the two years. Penn State Earliana had the lowest ascorbic acid value and Bestal was second lowest in all four localities, while Comet was highest at Orono and Kennebunk and Best of All was highest at Aroostook and Highmoor. In 1938 the majority of samples from Orono, Highmoor, and Kennebunk were over 0.06 mg. per gram greater in ascorbic acid content than those from Aroostook. In 1939 tomatoes grown in Aroostook were lower in ascorbic acid than those grown in Orono, but higher than those grown at Highmoor and Kennebunk. The majority of the samples were more than 0.04 mg. per gram higher in ascorbic acid in Aroostook, Orono, and Highmoor than in Kennebunk.

An analogous experiment in which four varieties of cabbages were used for the test crop confirmed the 1939 evidence obtained from tomatoes. These findings indicated that environmental agencies influenced the synthesis of ascorbic acid in tomatoes and cabbages and that geographical situation was not a contributing factor except insofar as environmental conditions were characteristic of that situation. An analysis of available weather data suggested that sunlight, rainfall, and probably temperature might have been causal agents in the variations in ascorbic acid content. As the tissue matured there was a definite rise in ascorbic acid concentration in the tomato and a decline in the cabbage. These phenomena were related to geographical situation to the extent that maturity rate was hastened or delayed by the climatic condition prevailing throughout the growing season in any one region. "Although variations effected by environment may be of greater magnitude than varietal differences, this does not lessen the importance of the varietal values. It is obvious that if a variety of low ascorbic acid content is subjected to adverse environmental influences, the tomato may well be rendered useless as a source of vitamin C. On the other hand, a high vitamin variety subjected to the same unfavorable conditions could still contribute materially to vitamin C requirements."

Serum phosphatase in infantile scurvy, H. SEWACHMAN (*Jour. Ped.*, 19 (1941), No. 1, pp. 38-41).—Serum phosphatase values for 18 infants with acute scurvy, for the most part before the institution of vitamin C therapy, ranged from 1.1 to 4.9, with an average of 3.2 Bodansky units, as compared with a range of from 4.5 to 12 and an average of approximately 7.2 units for normal infants and children. Values for 7 of the subjects during the progress of healing, in all but 2 cases with no vitamin D administration, showed, with one exception, a rise in phosphatase within approximately a week. The exception, the subject with the highest initial phosphatase value, showed on roentgenographic examina-

tion that considerable healing of a long-standing scurvy had already taken place. In view of the elevation of serum phosphatase in rickets and its subsequent decline on healing and the frequent presence of rickets and scurvy in varying degrees in the same infant, it is suggested that when a normal or high phosphatase value is obtained in an infant with acute scurvy the presence of some complicating condition such as rickets should be suspected.

Studies on the growth and development of male children receiving evaporated milk.—I. The effect of various vitamin supplements on growth in length and incidence of rickets during the first two years of life, T. F. RHODES, M. RAPOPORT, R. KENNEDY, and J. STOKES, JR. (*Jour. Ped.*, 19 (1941), No. 2, pp. 169-189, figs. 9).—Observations were made of 233 male infants receiving diets containing evaporated milk as the sole source of milk from the average initial age of 6 weeks until the age of 2 yr. The average growth in length was better than was expected according to the Kornfeld standards. At 3 mo., 1 yr., or 2 yr., there was no difference in length between the four groups represented by those receiving (1) irradiated evaporated milk, (2) nonirradiated evaporated milk plus cod-liver oil, (3) irradiated evaporated milk plus carotene, and (4) irradiated evaporated milk plus carotene and yeast. White children receiving the 1,500 units of vitamin D from cod-liver oil increased in length by a suggestively greater amount and colored children by a significantly greater amount than those receiving irradiated evaporated milk. The addition of 2,250 units of vitamin A in the form of carotene produced no significant effect on the rate of growth as compared with the effects of milk without vitamin supplements. The addition of powdered brewers' yeast, furnishing 250 units of vitamins B₁ and B₂ together with the carotene, produced a suggestively though not clearly significant greater growth in the white children, but no significant increase in length in the colored children. The incidence of roentgenographic rickets was practically the same at both levels of vitamin D intake (110 and 1,500 units daily), there being no incidence of marked rickets and only a 13.3 percent incidence of mild rickets. The various vitamin supplements had no influence on the incidence or severity of infections of the upper respiratory tract.

Vitamin K requirement of the newborn infant. R. L. SELLS, S. A. WALKER, and C. A. OWEN (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 441-445, fig. 1).—Blood prothrombin levels were followed daily for the first few days of life in infants receiving various doses of vitamin K as 2-methyl-4-amino-1-naphthol administered intramuscularly in (1) maintenance therapy consisting of small daily injections of the vitamin, (2) prophylactic therapy consisting of a single dose administered shortly after birth, or (3) curative therapy, in which case a single dose was given after depletion had already become established. The response of the infants to the various dosages and treatments, as judged by blood prothrombin values, is interpreted to indicate that the vitamin K requirement of the newborn infant is extremely low, approximately 1 μ g. of the synthetic vitamin per day. It is suggested that milk contains enough preformed vitamin K to meet this minimal requirement.

TEXTILES AND CLOTHING

[Textile research by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 414 (1941), pp. 45-49, figs. 2).—This progress report by P. B. Mack and H. Borton of the northeastern regional textile project in which more than 1,000 fabrics have been examined indicates the tests that have been found to serve as a basis for judging the quality of cotton, wool, and rayon fabrics.

Textile materials used for household purposes by farm families, M. E. FRAYSER (*South Carolina Sta. Bul. 341 (1942), pp. 15, fig. 1*).—Information concerning the use of textiles was secured by interviews with farm homekeepers or operators in 296 white and 294 Negro households, representing about 2 percent of the white and Negro farm owner and tenant households in the eight counties in the State surveyed in this study in 1936-37. This information is summarized and discussed with respect to the inventory, customary use, and replacement of various items of bedding; table coverings and napery; and window curtains and draperies. Economic and social data, obtained as a background for the interpretation, are summarized to show the number and size of the households, the size of the farms, and the education of the farm operator and homemakers. The investigation showed that cotton was more largely used for household purposes than any other textile material and that there was a relation between size of farm, economic status, tenure, race, and the provision of household textiles. "The limited supply of household textiles shown by the inventory and the relatively few additions made to the supply during the year suggest that farm families in South Carolina could be large consumers of products made from the cotton they raise. The figures emphasize the need for a better standard of living which would make possible greater outlays for such essential articles."

Effect of wear on wool and part wool fabrics (*South Dakota Sta. Rpt. 1941, pp. 70-71*).—Reports are given to indicate the progress of studies by B. Bailey and E. M. Pierson involving actual wear tests of trousers made from wool and part-wool fabrics.

Judging fabric quality, B. V. MORRISON (*U. S. Dept. Agr., Farmers' Bul. 1831, rev. (1942), pp. [2]+22, figs. 13*).—This is a revision of a publication noted earlier (*E. S. R., 82, p. 572*).

HOME MANAGEMENT AND EQUIPMENT

[Home management studies by the Illinois Station] (*Illinois Sta. Rpt. 1938, pp. 311-325*).—This progress report (*E. S. R., 82, p. 716*) summarizes an analysis by L. Bane and R. C. Freeman of farm-home records of 280 families showing the relation of consumption patterns to family spending plans and an analysis of home accounts kept for a continuous 5-yr. period (1933-37) by 89 Illinois farm families to show the relation of consumption and expenditure patterns in years when incomes were on the increase, and an analysis by Bane, Freeman, H. C. M. Case, and N. O. Thompson of the records of 117 families keeping both farm and home accounts in an effort to gain a more complete picture of the combined resources and income uses of the farm and farm home.

Family income and expenditures: Southeast region.—I, Family income. Farm series, D. S. BRADY, D. MONBOE, M. PERRY, and M. R. PRATT (*U. S. Dept. Agr., Misc. Pub. 462 (1941), pp. VI+208, figs. 6*).—This report presents information similar to that given for farm families in other regions surveyed in the consumer purchases study (*E. S. R., 84, p. 717*).

Housing for health (*Lancaster, Pa.: Sci. Press Ptg. Co., 1941, pp. 221, [pls. 2], figs. [20]*).—This volume, presented under the auspices of the Committee on the Hygiene of Housing of the American Public Health Association, includes the following papers: Health and Housing, by C. E. A. Winslow (pp. 7-17); Enforcement and Subsidy in the Control of Slums, by L. M. Graves and A. H. Fletcher (pp. 18-36); An Experiment in Housing Survey and Inspection Procedures for Health Departments, by G. C. Ruhland (pp. 37-47); Housing Codes, by M. G. Lloyd (pp. 48-53); Health Centers and Health Services in

Housing Projects, by J. C. Leukhardt (pp. 54-66); Heating, Lighting, and Noise Conditions in Recent Housing Projects, by A. A. Twichell (pp. 67-89); Heating and Ventilation of the Home, by C. E. A. Winslow (pp. 90-102); New Possibilities in Low-Cost Home Construction, by R. L. Davison (pp. 103-108); Planning for Recreation, by F. J. Adams (pp. 109-115); Family Life as the Basis for Home Planning, by S. H. Riemer (pp. 116-139); Social Effects of Good Housing, by F. S. Chapin (pp. 140-158) (Univ. Minn.); and Certain Characteristics of Urban Housing and Their Relation to Illness and Accidents, by R. H. Britten, J. E. Brown, and I. Altman (pp. 159-181). Basic principles of healthful housing are presented in an appendix.

What war is doing to the farm family, D. DICKINS. (Miss. Expt. Sta.). (*Jour. Home Econ.*, 34 (1942), No. 6, pp. 358-361).—This paper, dealing with the effects of national defense on the socioeconomic situation of the family, is based on studies noted elsewhere (E. S. R., 83, p. 286; 87, p. 321).

MISCELLANEOUS

Scientists face the world of 1942 (*New Brunswick, N. J.: Rutgers Univ. Press*, 1942, pp. [5]+80).—This includes the following essays: Scientists Face the World of 1942, by K. T. Compton (pp. 3-32); The Case for Biological Engineering, by V. Bush (pp. 33-45); and The Case for Agricultural Engineering, by R. W. Trullinger (pp. 46-62). Commentaries by H. N. Davis, D. Bronk, and S. W. Fletcher are appended.

A year's progress in solving farm problems of Illinois: [Fifty-first Annual Report of Illinois Station, 1938], compiled and edited by F. J. KELLHOLZ (*Illinois Sta. Rpt.* 1938, pp. 350, figs. 59).⁴

Science for the farmer: Fifty-fourth Annual Report of the Pennsylvania Agricultural Experiment Station, [1941], [S. W. FLETCHER] (*Pennsylvania Sta. Bul.* 414 (1941), pp. [4]+63, figs. 20).⁴

Farm research in South Dakota: Fifty-fourth Annual Report [of South Dakota Station, 1941], I. B. JOHNSON ET AL. (*South Dakota Sta. Rpt.* 1941, pp. [2]+97, figs. 4).⁴

What's new in farm science: Annual report of the director, [Wisconsin Station, 1941], II, compiled by N. CLARK and N. HOVELAND (*Wisconsin Sta. Bul.* 455 (1942), pp. [2]+87, figs. 34).—This supplements and completes the report previously noted (E. S. R., 86, p. 876), dealing with the subjects of milk and livestock production, poultry, hay and pasture, grains, weed control, soil management, potatoes, canning peas, vegetables, fruits, forestry, tobacco, factors affecting root development, and nosema disease in beekeeping.⁴

Plant science institutions, stations, museums, gardens, societies, and commissions in Central and South America (*Chron. Bot.*, 7 (1942), No. 2, pp. 49-61).—This list is a revised edition of the Central and South American part of the last world list,⁵ and has been discussed editorially (E. S. R., 87, p. 325).

A list of plant scientists in Central and South America (*Chron. Bot.*, 7 (1942), No. 3, pp. 97-133).—This list has been discussed editorially (E. S. R., 87, p. 325).

⁴ The experimental work not previously referred to is for the most part noted elsewhere in this issue.

⁵ *Chron. Bot.*, 4 (1938), No. 4-5, pp. 203-383.

NOTES

Arizona Station.—Dr. Alfred B. Caster of the Washington Station has been appointed assistant chemist. His work will include analyses of soils, irrigation water, fertilizers, and feeds, as well as research into problems of soil fertility.

Arkansas University and Station.—The resignations are noted of Rebecca Gifford, instructor and assistant in veterinary science, and Mildred Stenswick, instructor in home economics. Stewart Rowe and Runyan Deere, scientific assistants in the Cotton Branch Experiment Station, and W. H. Wiley, instructor in animal industry, have entered military service. Broder F. Lucas has been appointed professor of forestry and forest economist.

California University and Station.—Dr. Stanley B. Freeborn, assistant dean of the College of Agriculture and assistant director of the station, has joined the Army and is in charge of malaria research on the Pacific coast. Dr. W. V. Cruess, head of the division of fruit products in the station, has been awarded the first Nicholas Appert Medal by the Institute of Food Technologists.

Florida Station.—The station is looking into the possibilities of local production of a number of crops formerly largely imported. Among those with which trials are being made are a French-type teasel, sage, endive, and paprika.

Pliofilm, a new wrapping material which has been under test by the station for several years, has been found to be very effective in preserving fresh fruits and vegetables without appreciable losses of moisture, appearance, taste, vitamins, or quality either in cold storage or on the retail stand. Unfortunately, the material, a transparent synthetic plastic, consists largely of rubber hydrochloride, but it is believed to have distinct possibilities under normal conditions of rubber supply.

Hawaii University.—Gregg M. Sinclair has been appointed president vice Dr. David L. Crawford, retired.

Illinois University.—The industrial chemical investigations of the U. S. D. A. Regional Soybean Industrial Products Laboratory have been transferred from the university campus to the Northern Regional Research Laboratory at Peoria, leaving only an agronomic laboratory and oil, meal, engineering, and analytical units. Dr. T. H. Hopper, director of the laboratory, has been appointed chief of the analytical and physical chemical division of the Southern Regional Research Laboratory at New Orleans.

Kentucky University and Station.—The resignations are noted of Dr. B. S. White, Jr., as assistant professor and assistant in marketing, Drs. E. S. Hodge and W. S. Hodgkiss and G. Donald Sherman as assistant chemists, and W. L. Wright as instructor and assistant in animal husbandry. Military leave has been granted to Dr. A. T. Ringrose, assistant professor and assistant in poultry husbandry, and H. S. McGuire, assistant bacteriologist. Recent appointments include Dr. Henry Noble Sherwood as assistant bulletin editor, Dr. J. T. Skinner and Paul W. Scripture as assistant chemists, Emmet Dozier, Jr., as inspector in the creamery license section, Kenneth Anderson and James Browder as field agents in cream grading, Benn L. Hornbeck as junior forester, and J. Aaron Shrader as assistant bacteriologist.

Louisiana University and Station.—Recent appointments include Drs. Rue Jensen as assistant professor and assistant in veterinary science and J. E. Welch as assistant horticulturist, replacing, respectively, Drs. W. C. Schofield and Fred D. Cochran, who have been called to Army duty; Dr. Morris B. Hughes as geneticist; and Dr. Paul Johnson to assist in chemical analysis of new seedlings under the sweetpotato-breeding program.

Massachusetts Station.—Dr. Carl Olson, Jr. research professor of veterinary science, has reported for active duty as captain in the U. S. Veterinary Corps.

Michigan College and Station.—An apricot seedling contest has been arranged at the South Haven Substation in a search for native stock to use in crosses with leading commercial varieties grown on the Pacific coast in an attempt to develop hardy strains for Michigan. A quart sample of fruit is submitted with each sample entry. Cash prizes of \$25, \$15, and \$10 have been offered by the State Horticultural Society for the three best native seedlings.

George M. Grantham, who retired as associate professor and research associate in soils about a year ago, died June 13 at the age of 53 years. A native of Indiana, he received the B. S. degree from the University of Illinois in 1914 and the M. S. degree from the University of Nebraska in 1927. His service had been exclusively in Michigan, beginning in 1914 as an instructor in soils.

Dr. Eugene G. McKibbin, professor and research professor of agricultural engineering in the Iowa College and Station, has been appointed head of the department of agricultural engineering, effective September 1, vice H. H. Muselman, retired after 33 years' service.

Minnesota University and Station.—The position of vice director in the station has been redesignated as that of associate director. There has been no change in the status or duties of the position, which continues to be held by Dr. Forest R. Immer, who has immediate charge of all phases of experiment station administration. Effective July 1, Dr. Clayton O. Rost, professor of soils and soils chemist, became head of the division of soils. Other appointments in the division included Dr. Alfred C. Caldwell; Fred Bentley, now conducting research work; and Olaf C. Solne.

Dr. N. N. Allen, assistant professor of dairy husbandry and assistant dairy husbandman, has resigned to become associate professor of dairy husbandry in the University of Vermont.

Montana College and Station.—Dr. R. R. Renne, head of the department of agricultural economics, has been appointed State Price Officer of the U. S. Office of Price Administration, but will continue, on a limited basis, his relations with the station. Dr. Harold F. Hollands, professor of agricultural economics and agricultural economist, has been granted an indefinite leave of absence to become associated with the food supply section, Consumers' Division, of the U. S. War Production Board.

New York State Station.—Drs. B. R. Nebel, associate, and Mabel R. Nebel, assistant in research (pomology), have resigned. The former is to study in the University of Rochester Medical School, and has been succeeded by Dr. John Einset.

Ohio Station.—Owing to the war-time interest in homemade equipment exhibits prepared for Ohio Poultry Day, it has been arranged to keep some of them available for farmers and poultrymen who visit the station during the coming year. Exhibits to be retained include equipment for labor saving, feeding, and watering in the laying house and on the range, all wood except for nails; range shelters made of rough native lumber; an electric lamp brooder; rat eradication and control methods; and a brooder house equipped for farm grain storage.

Oklahoma College and Station.—Dr. Louis E. Hawkins, associate professor of animal husbandry at the college for 6 years and of late agricultural commissioner for the Kansas City Chamber of Commerce, has been appointed station vice director, succeeding Dr. Lippert S. Ellis, resigned to become regional director of research at Little Rock, Ark., for the Division of Land Economics, U. S. D. A. Bureau of Agricultural Economics.

Rhode Island College and Station.—Dr. Mason H. Campbell, for 14 years professor of dairy production at the University of Vermont and for the past year in commercial work, has been appointed dean of the School of Agriculture and Home Economics and director of the station, effective September 1.

South Dakota Station.—Recent appointments include Morris Rhlan, associate agricultural chemist; George F. Gastler, analyst; E. I. Whitehead, assistant chemist; and Erhardt Hehn, assistant agronomist. Dr. H. D. Anderson, associate chemist, has resigned to accept a position with the Michigan Public Health Department.

Utah College and Station.—C. J. Hogenson, extension agronomist since 1918 and associated with the institution since 1907, died in March in his sixty-eighth year. A native of Denmark, he was graduated from the college in 1899 and received the M. S. A. degree from Cornell University in 1906. In 1903-5 he was a soils expert with the U. S. D. A. Bureau of Soils. He has been succeeded by A. F. Bracken, associate professor of agronomy and associate agronomist and superintendent of the Nephi Dry Land Substation.

Dr. Wayne Binus, assistant professor of veterinary medicine and animal pathologist, has been called to active duty in the Army Veterinary Corps.

Wisconsin University and Station.—Dr. Ira L. Baldwin has been appointed chairman of the department of agricultural bacteriology, and Dr. C. L. Fluke chairman of the department of economic entomology. Vincent E. Kivlin succeeds Dr. Baldwin as assistant dean and John R. Barton becomes director of the farm short course, but each of these will continue his former work in agricultural education and rural sociology, respectively.

American Dairy Science Association.—The thirty-seventh annual meeting of this association was held at East Lansing, Mich., from June 23 to 26, 1942, with a registration of approximately 350, representing practically all States and drawn mainly from the agricultural colleges and experiment stations. The presidential address was given by H. F. Judkins. Of particular interest on the program were four symposia dealing, respectively, with the project on input as related to output in milk production, nutrition and reproduction in dairy cattle, problems in dairy manufacturing due to the war, and problems in the securing of milk quality. There were many indications of the shift in emphasis in research programs to meet war-time demands.

Tentative plans were discussed for a 1943 meeting to be held at the University of Missouri.

Association of Official Seed Analysts.—The 1942 annual meeting of this association was held at Lexington, Ky., in July with about 100 registrants from 23 States, the District of Columbia, and several provinces of Canada. Future meetings are to be deferred until the end of the war, but arrangements were made to carry on the work of the association by its officers. Charles A. Stahl of Lansing, Mich., was elected president; N. G. Lewis of Calgary, Alta., vice president; and Dr. Elva L. Norris of Manhattan, Kans., secretary.

EXPERIMENT STATION RECORD

VOL. 87

NOVEMBER 1942

No. 5

THE AGRICULTURAL EXPERIMENT STATIONS IN 1941

The publication of the latest report of the Office of Experiment Stations to Congress on the work and expenditures of the agricultural experiment stations has made available in convenient form another year's summary of the accomplishments of these institutions. The period covered is the fiscal year ended June 30, 1941.

The report indicates that during this period the research work of the stations proceeded for the most part along well-established lines, but with increasing emphasis upon those phases of immediate applicability to the national defense. Nearly 8,400 projects were under way. The financial support for this extensive program reached an aggregate of \$22,433,550.29. This was an increase of \$1,216,801.68 over the previous year, and was the high-water mark in the stations' history. The 1941 income consisted of \$6,862,500 from the four Federal-grant funds and \$15,571,050.29 of non-Federal funds, including State appropriations, special endowments and fellowships, fees, sales, miscellaneous sources, and the unexpended balances from the preceding year.

The Federal grants to the States, Territories, and Puerto Rico for agricultural research in 1941 compared with \$6,848,750 in 1940; the increase of \$13,750 consisting of \$7,500 to Hawaii, \$5,000 to Puerto Rico, and \$1,250 to Alaska under the Purnell Act. The amount of funds made available by the States in 1941 compared with \$14,367,998.61 in 1940, an increase of \$1,203,051.68. The income of the stations from sources other than Federal-grant funds was approximately \$2.27 for each \$1 of income from the Federal grants.

In addition to these direct sources of support the research work of the stations was aided and augmented by much cooperative effort. Extensive cooperation with the Department of Agriculture contributed to the progress of both groups of institutions. There was also much interstation cooperation which in the aggregate added considerably to the effectiveness of these research agencies.

In addition to a large amount of informal cooperation, nearly 1,350 new or revised formal memoranda of understanding covering cooperative research between bureaus of the Department and the State stations were recorded, involving nearly 1,200 major research under-

takings. All of the State stations, as well as all of the research bureaus and two of the action agencies of the Department, participated in this broad program, which involved from 8 to 55 research agreements per station and covered practical field problems of nearly every major aspect of farm production and rural life.

The amount of cooperative research brought to successful completion during the year was again relatively large. In all, more than 200 major cooperative studies were completed.

Interest in the defense activities of the Nation led to the focusing of research on the practical aspects developed out of broad studies begun in earlier years as recovery measures. The cooperative agricultural-adjustment study, which previously had been active on a national basis, was completed in all but six States and was being superseded in all but three States by the cooperative agricultural land use study for which it had laid much of the foundation. The results of numerous other cooperative studies were being used as a part of the procedure in agricultural planning.

Interstate coordination of agricultural research developed more rapidly than usual during the year. For example, the need to expedite movement of agricultural commodities from farm to market and from market to consumer developed into a problem of common concern to the majority of States. Informal community interest in marketing by regions resulted during the year in the formation of comprehensive formal cooperative studies of marketing of livestock and livestock products in two major regions.

The increasing recognition by Federal and State agencies of the importance of good nutrition to health and welfare, particularly in times of national emergency, has added impetus to the efforts of groups of States to solve some of the practical aspects of certain basic problems of human nutrition. Among the studies continued by these groups were those dealing with the nutritional status of college women, the ascorbic acid metabolism of college students, and the variation in the components and nutritive value of vegetables grown in the South.

In 1941, the Federal-grant research of the experiment stations was conducted under 3,235 separate projects, 515 being supported wholly or in part by Adams funds, 1,690 by Purnell funds, and 1,030 by Bankhead-Jones funds. Of the active projects, 600, or more than 18 percent, were revised or closed within the year. There were 374 new projects, 193 revisions, and 407 completions.

Information made available to the Office by the stations on their non-Federal research showed a total of 5,137 projects active in 1941. During the year, therefore, the experiment stations had 8,372 projects under investigation.

Their efforts to expedite solution of pressing problems and re-direct research on critical aspects of an emergency character are reflected in part in the project statistics for the year. The 600 Federal-grant projects revised or completed in 1941 compare with 435 in 1940, 429 in 1939, 405 in 1938, 333 in 1937, and 438 in 1936. According to the total of projects active during the year, the percentages revised or completed by these years, in the same sequence, were 18.5, 13.7, 14.2, 14.2, 12.6, and 17.2 percent.

The number of research workers on the station staffs in 1941 was 4,755, an increase of 162 over 1940. The increase consisted of 45 full-time research workers and 117 whose time was divided between research and resident teaching or extension, or research and both resident teaching and extension work. Of the 4,755 technical workers in 1941, 2,303 gave their full time to research while the time of the other 2,452 was devoted partly to research and partly to resident teaching or extension work or both.

The publications of the stations in 1941 included 834 bulletins and circulars in the regular series, 2,411 articles in scientific journals, and 701 miscellaneous publications. The comparable figures for 1940 were 732, 2,386, and 486, respectively.

It is estimated that the station publications collectively comprised nearly 50,000 printed pages. Necessarily, therefore, although 106 of the 128 pages of the report are devoted to a summary of activities, no attempt has been made to cover all of the research projects active during the year or even to present a complete review of the results obtained. The aim has been to make selection within the several fields to depict the wide range of the subjects studied and the findings having greatest significance in the solution of the current problems.

The general plan followed in the discussion is that of recent years, but the space available has been curtailed to less than 50 percent of that in the corresponding report for 1940. In view of this situation and in order to expedite the publication of findings where possible, special provision was made for the transfer of the sections dealing with agricultural engineering and home economics to other mediums of publication. Notwithstanding these changes it is hoped that the compendium will be useful as the most complete presentation available of what has been accomplished by the stations in this year of pre-war preparation.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY AND MICROTECHNIC

Liebig and after Liebig: A century of progress in agricultural chemistry, edited by F. R. Moulton (*Amer. Assoc. Adv. Sci. Pub.* 16 (1942), pp. [71]+111, [pl. 1], figs. [14]).—A symposium of papers presented before the sections of chemistry and agriculture of the American Association for the Advancement of Science at Philadelphia on December 30, 1940, in commemoration of the hundredth anniversary of the publication of Liebig's Organic Chemistry in Its Applications to Agriculture and Physiology. These papers are as follows: Justus von Liebig—Man and Teacher, by C. A. Browne (pp. 1-9) (U. S. D. A.); Liebig's Influence in the Promotion of Agricultural Chemical Research, by H. R. Kraybill (pp. 10-18) (Purdue Univ.); Liebig and the Chemistry of Proteins, by H. B. Vickery (pp. 19-29) (Conn. [New Haven] Expt. Sta.); Liebig and the Chemistry of Enzymes and Fermentation, by A. K. Balls (pp. 30-39) (U. S. D. A.); Liebig and the Chemistry of Animal Nutrition, by P. E. Howe (pp. 40-47); Liebig and the Chemistry of the Soil, by R. Bradfield (pp. 48-55) (Cornell Univ.); Liebig—the Humus Theory and the Role of Humus in Plant Nutrition, by S. A. Waksman (pp. 56-63) (N. J. Stas.); Liebig and the Chemistry of Mineral Fertilizers, by H. A. Curtis (pp. 64-70) (Univ. Mo.); Liebig and the Law of the Minimum, by C. A. Browne (pp. 71-82) (U. S. D. A.); and Mineral Requirements of Plants as Indicated by Means of Solution Cultures, by B. E. Livingston (pp. 83-111).

[Chemical investigations by the Idaho Station] (*Idaho Sta. Bul.* 244 (1942), pp. 23, 31-33, 35).—These include the development by L. Verner and C. F. Dietz of prune nectar as a new Idaho product and studies of the effect of stage of maturity on feeding value of arrowleaf balsamroot, by D. W. Bolin and W. M. Beeson; the cobalt content of some Idaho feeds, by Bolin; and on the use of ground raw soybeans added to dehydrated alfalfa meal to retard the destruction of carotene, by Bolin, C. E. Lampman, and L. R. Berg.

[Chemical investigations by the Indiana Station]. (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt.* 1941, pp. 12-16).—Chemical studies on hybrid corn are reported upon by D. M. Doty; fractionation of glycerides of soybean oil and other liquid vegetable fats, by A. W. Kleinsmith, H. R. Kraybill, and M. H. Thornton; the production of nonbreak soybean oil, by K. E. Eldridge, Kraybill, and Thornton; spectral absorption studies on vegetable oils, by J. H. Mitchell, Jr., and Kraybill; nonfat constituents of soybean oil, by Thornton and Kraybill; carbohydrates of the soybean, by E. D. Walter; improvements in the photoelectric spectrophotometer, by F. P. Zschelle; carotenoid pigments and content of corn grains, by Zschelle, J. W. White, and A. M. Brunson; carotenoid pigments and content of vegetables, by Zschelle, B. W. Beadle, and Kraybill; vitamin A in butterfat, by Zschelle, C. L. Shrewsbury, Kraybill, and R. L. Henry; the spectroscopy of chlorophyll, by Zschelle, C. L. Comar, and G. D. Harris; and work on photosynthesis, by Zschelle and L. F. Green.

[Chemical investigations by the Puerto Rico Station]. (Partly coop. U. S. D. A. et al.). (*Puerto Rico Sta. Rpt.* 1940, pp. 11-18, 19-22, 23-33, 44-49, 85-93, figs. 10).—These include control of moisture content of vanilla beans in processing,

limitation of enzyme activity by excessive drying, relation of splitting of beans to length of exposure to killing agents, superiority of dilute concentrations of ethylene gas over greater concentrations, high content of peroxidase in vanilla beans, increase of respiration by ethylene gas as killing agent for vanilla beans, freezing to decrease respiration of vanilla beans, effect of killing agents on respiration rate during processing period, various degrees of maturity in relation to processing, higher vanillin content and total solids values in extracts of mature beans, standardized organoleptic tests to measure value of cured beans, and organoleptic tests of extracts by the U. S. Department of Agriculture and similar tests of cured beans in Mayaguez, all by F. E. Arana, A. K. Balls, A. G. Kevorkian, and E. Hernández Medina; standardization of methods of determining quinine in bark and variation of quinine content of bark in same tree, by H. T. Love; increased citral content in oil and decreased percentage of oil and grass tonnage by shading, increase in yield of lemon grass by lengthening growth period, the yields of grass, oil, and citral per acre per week in relation to the growth period, a fertilizer-constituent experiment with lemon grass, increase in tonnage of lemon grass on Catalina clay soils by potassium fertilizers, nitrogen plus potash as a requirement for highest yields of citral per acre, increased applications of nitrogen as a cause of increased lemon grass tonnage and citral yield per acre, and increase in yield of oil obtained in distillation of lemon grass by adding sodium chloride, and use of rock salt in distillation water to increase yield and quality of bay oil and chemical and physical properties of bay oil obtained by distillation from salt solution, all by A. R. Villamil and N. G. Arrillaga; lemon grass residue as a possible cattle feed, by Villamil and A. Arroyo; relation between carbohydrates and toxic constituents in *Derris* and *Tephrosia* roots, modified method of sugar determination, and carbohydrates and toxic constituents in normal plants of *D. elliptica*, all by R. H. Moore and M. A. Jones; wine from juice of Puerto Rican oranges and the influence of maturity on the amount of juice, acid, and sugars in local oranges, by J. O. Carrero; and the nonvolatile acids and flavor of the soursop, vitamin C content of the fruit, identification of a mixture of malic, citric, and isocitric acids, separation of light alcohols and acetaldehyde in determining flavor, flavor influence of an oil composed of several esters, and various caproates as contributors to soursop flavor, and the nonvolatile acids of the carambola, identification of traces of malic and citric acids, and oxalic acid as source of the acidity, all by E. K. Nelson and A. L. Curl.

The chemical composition of Atlas and Dwarf Yellow milo plants in relation to chinch bug resistance, J. E. WEBSTER and V. G. HELLER (*Oklahoma Sta. Tech. Bul.* 12 (1942), pp. 29, figs. 3).—Analysis of these sorghum varieties at growth stages up to but not beyond the heading stage gave the following indications as to differences in resistance to chinch bug injury.

The solids content of the juice, generally higher in the susceptible milo, did not seem to show a significant difference. The milo plants were consistently higher in ash content under all conditions, and this value would seem to merit further consideration. Neither of the acidity measurements (total titratable acidity and pH) showed significant differences. Astringency values, including tannins, do not seem capable of explaining any of the known differences in resistance. Sugars in both varieties increased progressively at least up until heading time. Although Atlas (resistant) is known as a sweet sorghum, during the periods under examination the milo plants invariably contained the more sugars. Atlas rarely contained any appreciable sucrose, while the milo always had some and generally large quantities. The percentage of sucrose in the milo at late afternoon was always much greater than in the morning, and

the difference between the two varieties at this time of day seems fundamental and more noteworthy than any other found. There were marked differences in the total nitrogen content of the plants and juices, Atlas normally showing a decreasing content with growth while the milo percentages increased. Conductivity studies indicated little difference between the two varieties. Analyses for chlorides were made on many samples, and the higher values usually found for the milo may be significant. There appeared to be no significant correlation between resistance and the catalase, oxidase, or peroxidase activity. The milo plants were generally found to be higher in phosphorus, potassium, and calcium. The hydrocyanic acid content of both varieties was found to be generally the same. Separate analyses of leaves and stalks did not yield significant data.

Supplement to soybean protein—resume and bibliography, G. H. BROTHER, A. K. SMITH, and S. J. CIRCLE (*U. S. Dept. Agr., Bur. Agr. Chem. and Engin., [1942], ACE-62, Sup. 1, pp. 11*).—This supplement to the bibliography already noted (*E. S. R.*, 86, p. 150) gives additional classified references under the headings agronomic and general, treatment and processing of whole soybeans, soybean protein extraction and characteristics, hydrolytic products of soybean protein, enzymes of the soybean, and industrial applications.

Studies on the ceruleomolybdate determination of phosphorus, B. R. BERTRAMSON. (*Oreg. Expt. Sta.*). (*Soil Sci.*, 53 (1942), No. 2, pp. 135-141, figs. 2).—The author adapted a modification of the Denigès colorimetric method (*E. S. R.*, 44, p. 611) for use with a photoelectric colorimeter in place of the visual instrument. Adjustment of the pH of the test solution according to the procedure of Dickman and DeTurk (*E. S. R.*, 70, p. 7) was made a part of the improved technic. By the use of a photoelectric colorimeter conformity of the test to Beer's law was demonstrated for from 0.05 to 1.75 p. p. m. of phosphorus as o-phosphate. As much as 4.5 milliequivalents of ammonium or magnesium sulfate could be present in 50 cc. of the final test solution without seriously affecting the results. At higher concentrations the magnesium ion apparently exerted a greater effect upon color development than did the ammonium ion.

An apparatus for the effective preservation of the stannous chloride solution under hydrogen for an unlimited period of time is described. The preparation and storage of the other reagents, thus ensuring consistent results over a long period and providing for speed and accuracy in routine analysis, were also studied.

Applicability of the Mitscherlich method to the determination of available phosphate in some Iowa soils, C. D. HOOVER and A. G. NORMAN. (*Iowa Expt. Sta.*). (*Soil Sci.*, 53 (1942), No. 5, pp. 329-340, figs. 3).—Experimentally determined yield curves for oats, obtained by plotting the mean yields of replicate pots treated with successive increments of phosphate, gave reasonable agreement with the logarithmic curves of the Mitscherlich equation. The increases in yield produced by successive increments were not in every case, however, statistically significant. The phosphorus effect factor c , for Victoria-Richland oats was distinctly lower than the constant used by Mitscherlich. Another variety, closely related, gave a value almost twice as great. There was some measure of agreement between the ranking of nine Iowa soils in level of available phosphate as tested by the Mitscherlich procedure with rankings obtained by the chemical availability tests of Truog (*E. S. R.*, 64, p. 312) and Bray (*E. S. R.*, 62, p. 13). Close agreement was found between the results of the Mitscherlich tests on these soils and the responses on the undiluted soils given by successive crops of Sudan grass and wheat in the greenhouse after application of the equivalent of 400 lb. of superphosphate per acre.

To be of practical value under Iowa conditions, the Mitscherlich method should be so modified that the effect factor would be determinable separately in each test. This modification would call for the use of a minimum of 12 pots for each soil instead of 6, and the use of 3 small increments of phosphate to delineate satisfactorily the lower part of the yield curve, or, alternatively, increments each double its predecessor.

A comparison of some methods for the determination of soil organic matter, H. W. SMITH and M. D. WELDON. (Nebr. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 177-182).—The authors determined the organic matter content of 158 soils, using Schollenberger's titration method (E. S. R., 65, p. 504); a modification of Robinson's hydrogen peroxide procedure (E. S. R., 57, p. 310) in the form described by Judd and Weldon (E. S. R., 81, p. 338); wet combustion, an apparatus similar to those described by Adams (E. S. R., 74, p. 299) and by Alexander and Byers (E. S. R., 68, p. 15); and a modification of the Walkley-Black method (E. S. R., 70, p. 742), in which the titration was made with potassium permanganate solution as the only standard.

The proposed change in the Walkley-Black procedure improved the titration by increasing the visibility of its end point. High correlation between the results from the rapid methods and those from the modified Robinson and wet combustion procedure was found, with the exception of the samples to which organic material had been added recently. This exception is not in agreement with the work of Baker (E. S. R., 75, p. 300). It is suggested that data obtained by the rapid methods be reported as found, that is, as milliequivalents of oxidized material per gram of soil. The rapid methods may be used on calcareous soils; the Robinson method cannot be used successfully, and wet combustion necessitates both total and inorganic carbon measurements. The rapid methods are economical of both time and chemicals. The Walkley-Black method is twice as fast and one-half as expensive as Schollenberger's method, its nearest competitor in these respects.

Analysis of plant extracts for chlorophylls a and b by a photoelectric spectro-photometric method, C. L. COMAR and F. P. ZSCHEILE. (Purdue Univ.). (*Plant Physiol.*, 17 (1942), No. 2, pp. 198-209, fig. 1).—By the simple, rapid, and accurate method described, an acetone extract is made from fresh leaf material (12 plant sources used), the fat-soluble pigments are transferred to ether, the acetone is removed, and the solution dried with Na_2SO_4 . Spectroscopic analysis for chlorophyll a and b is made at wavelengths 6,600 and 6,425 m. μ . The reliability of values obtained from other wavelengths depended considerably on the carotenoid content. The chemical precautions and instrumental conditions essential for quantitative results are discussed.

The concentration and assay of avidin, the injury-producing protein in raw egg white, R. E. EAKIN, E. E. SNELL, and R. J. WILLIAMS (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 535-543).—The avidin assay method described in detail is an adaptation of the yeast method for the determination of biotin. The protein samples to be tested are introduced into sterile biotin solutions, and aliquots are set up in duplicate, the assay of one set being carried out without heat sterilization of the samples. The duplicate set is sterilized by steaming 15 min. at 100° C. This treatment denatures the inactivating protein, and completely releases the biotin. The difference in biotin content between heated and unheated aliquots (as measured by yeast growth) gives a direct measure of the amount of biotin-inactivating protein present in the samples tested. The amounts of biotin in the aliquots are read from curves obtained by plotting the readings given by the biotin standards. One unit is defined as the amount of material capable of inactivating 1 γ of biotin.

Gelatin, edestin, peptone, gliadin, hemoglobin, and tobacco mosaic virus were found to have no biotin inactivating activity. Potent concentrates prepared from fresh egg white did possess such activity, less than 350 parts of some preparations being able to inactivate 1 part of biotin. Avidin was separated from egg white by (1) acetone precipitation of the proteins and extraction of the curds with 2 percent ammonium sulfate in which the active protein was soluble; (2) half saturation with ammonium sulfate and acidification with acetic acid which precipitated the bulk of the proteins but left the avidin in solution; and (3) careful coagulation by heat which removed part of the inactive protein. The first of these three methods proved most satisfactory and is described in detail. The avidin concentrate was relatively heat-stable, responded to certain protein tests, and, judging by solubilities, was neither an albumin nor a globulin.

A quantitative method for assay of tobacco-mosaic virus protein, V. L. FRAMPTON. (Cornell Univ.). (*Phytopathology*, 32 (1942), No. 7, pp. 618-622, figs. 2).—The precipitin reaction may be used in a rapid and accurate determination of tobacco-mosaic virus protein. The amount of N and P found in the precipitate formed in this reaction is proportional to the amount of virus protein added. The ratio of virus protein N to antibody N in the precipitate was found to be 4.8.

Haemoglobinometry, C. RIMINGTON (*Brit. Med. Jour.*, No. 4231 (1942), pp. 177-178).—The method outlined for the determination of total blood pigment involves conversion of all heme pigments present into pyridine-hemochromogen. The intensity of absorption of the latter at about 550 m μ is measured with the Hilger-Nutting photometer, using a suitable filter. From the calibration factor, obtained by using known weights of pure hemin instead of blood, the hemoglobin content of the blood is then calculated. The method is rapid and considered sufficiently accurate for clinical purposes.

The evaluation of fluorophotometers to be used in the thiochrome assay for vitamin B₁, J. R. LOOFBOUROW and R. S. HARRIS (*Cereal Chem.*, 19 (1942), No. 1, pp. 151-168, figs. 8).—Five commercial fluorophotometers of varying design and construction were tested to determine their reliability and precision. It is concluded that "a heating period of 10 to 15 min. is sufficient to attain stable operating conditions in the fluorophotometers tested. All instruments tested have sufficient sensitivity, linearity, and reproducibility of readings to permit the evaluation of thiamin at levels of 0.1 to 1.5 μ g. per 15 cc. of thiochrome solution, with probable errors of the order of 0.0001 to 0.0021 μ g. of thiamin per cubic centimeter of thiochrome solution. The variation in readings due to line voltage fluctuations is of the order of 2 percent per volt at 110 v. in instruments without balanced photocell circuits. This is reduced to the order of 0.1 percent per volt in instruments employing balanced circuits, or in unbalanced instruments when used with line voltage regulating transformers on lines with good frequency regulation. The rate of destruction of thiochrome in these instruments is insufficient to cause serious error in readings, but in two instruments . . . It is high enough to make advisable the taking of readings at a constant time after introducing the sample into the instrument."

The estimation of thiamine in urine, E. EGAÑA and E. P. MEIKLEJOHN (*Jour. Biol. Chem.*, 141 (1941), No. 3, pp. 859-870).—The procedure, described in detail as to reagents, methods, and preparation of standards, consists in general of collection of the urine under acetic acid as a preservative; preliminary washing of the acidified urine, if of low thiamin content, with isobutyl alcohol to remove fluorescent interfering substances; separation of

the aqueous and alcohol layers by centrifuging; adjustment of the aqueous layer to pH 4.2-4.5 with acetic acid, with bromocresol green as external indicator; removal of thiamin by adsorption by rapid filtration of this solution through Decalco; elution of the thiamin by a minimum of shaking of the Decalco with potassium chloride solution in a closed centrifuge tube; treatment of this mixture with the potassium ferricyanide reagent, followed by the addition of the sodium hydroxide solution; extraction of the colored reaction product with isobutyl alcohol; transfer of a portion of the isobutyl alcohol solution, separated by centrifuging, to a Pyrex test tube; and comparison of the fluorescence exhibited in ultraviolet light with that of standards in identical but sealed tubes containing known amounts of synthetic thiochrome dissolved in isobutyl alcohol. The minimum of shaking and the order of adding the reagents prevent overoxidation of the thiamin. On the basis of the tests made, the method is considered applicable to quantities of thiamin varying from 0.2 γ to 2.0 γ in 5 cc. of isobutyl alcohol in the final comparison. With dilutions greater than 1:20,000,000 of thiochrome, an error of about 15 percent is introduced.

The fluorometric determination of riboflavin in urine and other biological fluids, V. A. NAJJAR (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 355-364).—The direct procedure described involved acidification of the diluted or undiluted urine with acetic acid, oxidation of interfering fluorescent substances with KMnO_4 , followed by H_2O_2 , and extraction of the riboflavin with pyridine, which was made to separate out as a surface layer by saturation of the aqueous solution with anhydrous Na_2SO_4 . By the addition of butyl alcohol, which is miscible with pyridine but not with water, the separation of the riboflavin from the water phase was made complete. The fluorescence of the pyridine-butyl alcohol solution was measured in a Pfaltz and Bauer fluorophotometer, the observed fluorescence being corrected for that of the solvent by subtracting the fluorescence of the blank in which the riboflavin had been destroyed by exposure to a mercury-vapor lamp or to direct sunlight. The concentration of the riboflavin was determined by comparing the fluorescence of the unknown sample with that of a riboflavin standard, measured at the same time with an exciting light of identical intensity. The direct method was found applicable to urines containing as little as 0.05 γ -0.1 γ of riboflavin per cubic centimeter. By the indirect method, generally recommended for urines containing less than 0.1 γ per cubic centimeter and for those highly pigmented, the riboflavin was adsorbed on freshly precipitated PbS and eluted with a solution consisting of 70 cc. of water, 30 cc. of pyridine, and 2 cc. of glacial acetic acid. The eluate was oxidized, decolorized, extracted with butyl alcohol, and carried through the procedure essentially as in the direct method. Either the direct or the indirect procedure gave satisfactory results with known solutions of different concentrations, and quantitative recovery of riboflavin added to urine samples. Comparative analyses by the indirect procedure and by the bacterial growth method of Snell and Strong (*E. S. R.*, 82, p. 587) showed very satisfactory agreement between the two methods.

Riboflavin analysis of cereals: Application of the microbiological method, J. S. ANDREWS, H. M. BOYD, and D. E. TERRY (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 3, pp. 271-274, figs. 2).—The microbiological method of Snell and Strong (*E. S. R.*, 82, p. 257), applied in direct assay of the solid, finely ground cereal, gave lower values as the weight of the sample was increased. This tendency was decreased but not eliminated by the use of extracts prepared by autoclaving the flour with water and centrifuging. The resulting assay values were materially lower than those obtained by use of the solid

material, but apparently not for lack of thorough extraction of the flavin, since preliminary treatment of the sample with HCl failed to increase the riboflavin content of the extract. Recovery of riboflavin added to the flour greatly exceeded the theoretical, but decreased toward 100 percent as the weight of the sample used was increased. These results indicated that the cereal flour contained factors other than riboflavin that exerted both stimulating and inhibitory influences on the growth of the organism. Treatment of the sample with takadiastase prior to removing the undissolved solids resulted in still lower values than those obtained with simple water extracts. The digested extracts gave uniform values over the range of assay levels employed and in recovery experiments permitted relatively constant recovery at near the theoretical level. The mechanism of these observations was not clear, but evidence was obtained that diastasis of the starch was one factor.

Aqueous and digested extracts were treated with the adsorbent, Florisil (Supersorb), and the eluates examined fluorometrically. Values for the two types of extracts were in fairly good agreement, although the enzymatic hydrolysis appeared to give slightly improved extraction. When the digested extracts were used, results obtained by microbiological and fluorometric procedures were in close agreement and indicated a riboflavin content of 0.35 and 1.03 $\mu\text{g.}$ per gram of patent and whole wheat flour, respectively.

Destruction of riboflavin by light, R. R. WILLIAMS and V. H. CHELDELIN (*Science*, 96 (1942), No. 2479, pp. 22-23).—The destruction of riboflavin in a solution initially containing 0.1 γ per cubic centimeter was determined after exposure of the solution to light under different conditions in which the time, temperature, and pH of the solution were varied. The experiments were carried out in early afternoon on sunny days in a well-lighted room simulating usual kitchen conditions, and the results showed that increases either in temperature or in alkalinity accelerated the destruction of riboflavin at a quite rapid rate. Other tests were conducted in the dark, and no destruction occurred. Fresh skim milk and beaten raw eggs heated in the light at 100° C. for varying periods suffered rapid destruction of their riboflavin contents. The rate of destruction was slower than in clear solutions of riboflavin, and the destruction in eggs was less than in milk. No appreciable destruction occurred when these foods were heated in the dark (closed pan, autoclave). It is pointed out that the opacity of many foods would tend to prevent excessive riboflavin losses during cooking.

Chemical determination of nicotinic acid content of flour and bread, D. MELNICK, B. L. OSER, and L. SIEGEL (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 12, pp. 879-883).—The method, outlined in some detail as to reagents, procedure, readings, and calculations, is based on that of Melnick and Field (*E. S. R.*, 85, p. 584). A water extract obtained by autoclaving a sample suspended in water is concentrated to small volume, treated with an equal volume of concentrated HCl, and after dilution is heated on a boiling water bath to liberate any nicotinic acid from its compounds. The hydrolyzate, treated with absolute ethyl alcohol, is subjected to preferential charcoal adsorption, which removes interfering pigments without removal of nicotinic acid. The filtrate is neutralized and then treated with cyanogen bromide and an aniline solution. The yellow color which results is measured in a photoelectric colorimeter. Calculation is based on a suitable correction for residual interfering color and on the increment in photometric density obtained with a known addition of nicotinic acid to an aliquot of the test solution. This method was shown to be satisfactory in that it gave complete preliminary aqueous extraction, reproducible results, and a high recovery of added nicotinic acid. The specificity of the method for nicotinic acid in cereal products was demonstrated by the fact that the values

obtained agreed very well with those obtained by the microbiological procedure of Snell and Wright (E. S. R., 87, p. 12).

Whole-wheat flours analyzed contained from 5.2 to 6.5 mg. of nicotinic acid per 100 gm.; patent flour from 1.3 to 1.9 mg. The good agreement between calculated and determined nicotinic acid values in a number of breads indicated that only small losses of nicotinic acid occurred during the fermentation and baking processes.

The use of bacteria in the chemical determination of total vitamin C, I. C. GUNSALUS and D. B. HAND. (Cornell Univ.). (*Jour. Biol. Chem.*, 141 (1941), No. 3, pp. 853-858).—The method described is based upon the ability of certain strains of *Bacterium coli* to reduce dehydroascorbic acid to ascorbic acid quantitatively. The procedure, as applied to milk, involves the addition of from 0.5 to 1.0 cc. of a resting suspension of the organism to 10 cc. of milk and incubation at 40° [C.] for 15 min., followed by the addition of 20 cc. of 0.1 N H_2SO_4 and direct titration with 2,6-dichlorophenolindophenol dye to an end point remaining pink for 30 sec. For the determination of total vitamin C in food products other than milk, the extract is brought to pH 6.2-6.6 before reduction, and the bacteria are activated by mixing 1 cc. of the suspension with 1 cc. of 10 percent glucose 15 min. before the addition of the extract to be analyzed. The method is specific for the determination of oxidized ascorbic acid in that no oxidation product other than dehydroascorbic acid is reduced by the organism. However, the oxidation product of *D*-isoascorbic acid is also reduced. Data presented in comparison of the reduction by *B. coli* with reduction by H_2S show agreement between the two methods even in the presence of nonspecific oxidizing agents such as copper or H_2O_2 . Results obtained by application of the bacterial reduction to milk and canned fruit and vegetable juices are given. These data indicate that the method is not applicable to all biological materials, since the organism failed to reduce dehydroascorbic acid added to the sauerkraut and composite vegetable juices, but acted instead as an oxidation catalyst to decrease the ascorbic acid present. The bacterial reduction method was applied satisfactorily to urine.

The determination of vitamin C in urine, G. T. MEIKLEJOHN and C. P. STEWART (*Biochem. Jour.*, 35 (1941), No. 7, pp. 761-769, figs. 3).—The method described for determining the total ascorbic acid in urines was based on that of Scarborough and Stewart,¹ which was modified to carry out the reduction with $SnCl_2$ rather than H_2S ; this permitted the operations of reduction and hydrolysis to be combined and the time for hydrolysis to be measurably shortened. Since the method involved both reduction and hydrolysis of the urine filtrates, that part of the vitamin present as dehydroascorbic acid and also that present in a nonreducing combined form were converted to ascorbic acid, which was determined by an enzymic procedure that served to exclude the effect of certain interfering substances in the final titration with 2,6-dichlorophenolindophenol. The procedure involved acidification of the urine with acetic acid; clearing, if dark or of high specific gravity; reduction and hydrolysis by treatment of the urine, or the filtrate after clearing, with the $SnCl_2$ reagent and refluxing under a stream of N_2 on a boiling water bath for 90 min.; cooling, and clearing by the addition of mercuric acetate solution, followed by precipitation with H_2S . After filtration, an aliquot was set aside for titration after removal of H_2S by aeration with CO_2 , and another aliquot was buffered to pH 6.0 and oxidized enzymically for 30 min. in the presence of autolyzed cucumber juice. The resulting solution was treated with 50 percent HPO_4 and centrifuged, and an

¹ *Biochem. Jour.*, 31 (1937), No. 12, pp. 2232-2239, figs. 3.

aliquot of the supernatant liquid was titrated with indophenol solution. The difference between the results of the two titers, expressed as ascorbic acid and with due allowance for the dilution involved, represented total ascorbic acid in the urine. Some analyses are reported. The scorbutic urines showed very low concentrations of ascorbic acid, and occasionally none was detectable. A few dried vegetables were also analyzed.

Determination of ascorbic acid in whole blood, C. A. KUETHER and J. H. ROE (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 487-489).—The method, described in some detail, involves removal of the oxyhemoglobin, by reduction through alternate evacuation and treatment with CO, under pressure, before deproteinization with HPO_3 . This preliminary step is necessary, since the oxygen set free from the oxyhemoglobin when blood is thus deproteinized serves to oxidize any ascorbic acid present. The filtrate remaining after filtering off the precipitated proteins is analyzed for reduced ascorbic acid by a modification of the method of Mindlin and Butler (*E. S. R.*, 80, p. 728). In nine analyses of normal human blood and normal and scorbutic guinea pig blood to which pure ascorbic acid was added, the recoveries obtained ranged from 90 to 110 percent.

The occurrence of free and bound biotin, J. O. LAMPEN, G. P. BAHLER, and W. H. PETERSON. (*Wis. Expt. Sta.*). (*Jour. Nutr.*, 23 (1942), No. 1, pp. 11-21, fig. 1).—Biotin was determined by a microbiological method employing a strain of *Olostridium butylicum*. This organism, on a basal medium of 2 percent glucose, 0.1 percent asparagine, and 0.11 percent salts, required only the addition of biotin for maximum growth, which took place under anaerobic conditions. Turbidity as read in an Evelyn photoelectric colorimeter was used as a measure of growth. The method, based on these principles and outlined in some detail, was applied to aqueous or acid- or enzyme-hydrolyzed extracts of the material being assayed. The extract was added to the basal medium, the mixture was inoculated and incubated, and the turbidity developed was compared with that developed in an inoculated control tube containing biotin. Only the free biotin was obtained by aqueous extraction; acid, enzyme, or autolytic hydrolysis was required for liberation of bound biotin. Optimal acid hydrolysis was obtained by treatment with 2 N H_2SO_4 for 2 hr.

Assays showing the occurrence of free and bound biotin in a variety of natural materials indicated that the biotin of yeast and animal products occurs chiefly in a water-insoluble, firmly bound combination; that vegetables, green plant materials, and fruits contain a water-extractable form; and that seeds and nuts have considerable amounts of bound biotin.

Isolation of biotin (vitamin H) from liver, V. DU VIGNEAUD, K. HOFMANN, D. B. MELVILLE, and P. GRÖGAY. (Cornell Univ. et al.). (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 643-651, fig. 1).—This paper, elaborating upon a preliminary report (*E. S. R.*, 86, p. 12), describes the procedure for the isolation of the methyl ester of biotin from a liver concentrate. This concentrate had been prepared from the alcohol-insoluble fraction of beef liver by high pressure hydrolysis, precipitation of the inert material with alcohol and acetone, and precipitation of the active substance with phosphotungstic acid, followed by decomposition of the precipitate with barium hydroxide. For isolation of the biotin this concentrate was evaporated to dryness, and the gummy residue obtained was esterified by refluxing with absolute methanol containing 5 percent of dry HCl gas; the ester, concentrated in vacuo to a sirupy solution, was washed, neutralized with solid potassium bicarbonate, and extracted with ethyl acetate. This extract, washed with water and dried over sodium sulfate, was taken up in chloroform and further purified by repeated chromatographic adsorption on

aluminum oxide, using an acetone-methanol mixture as the eluent. Eluates of high vitamin H activity, as determined by microbiological assay, were combined and re-esterified, and the ester hydrochloride converted to the free ester which, by repeated crystallization and sublimation, gave crystals possessing a constant biological activity of 27,000 (± 10 percent) vitamin units per milligram and a constant melting point of 166° – 167° [C.]. The analytical data agreed most closely with the empirical formula $C_{11}H_{16}O_4N_2S$.

The preparation of free crystalline biotin, V. DU VIGNEAUD, K. HOFMANN, D. B. MELVILLE, and J. R. RACHELE. (Cornell Univ.). (*Jour. Biol. Chem.*, 140 (1941), No. 3, pp. 763–766, figs. 2).—Free biotin was prepared in crystalline form by saponification of the ester with cold alkali, followed by acidification of the mixture with HCl. The long thin needles that separated were recrystallized from water. The empirical formula was shown to be $C_{10}H_{16}O_4N_2S$. The titration curve corresponded to that of a monocarboxylic acid. No specific absorption in the ultraviolet and near ultraviolet region was found.

The isolation of biotin from milk, D. B. MELVILLE, K. HOFMANN, E. HAGUE, and V. DU VIGNEAUD. (Cornell Univ.). (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 615–618).—In the interest of preparing biotin on a larger scale than it could be obtained from liver, as described above, a commercial biotin concentrate prepared from milk and containing from 1 to 2 mg. of biotin per gram of solids was used as the starting material. The method of preparation, described in detail, involved treatment of the concentrate with acidic methanol to give the biotin methyl ester, which was chromatographically adsorbed, first, on Decalco and then on activated alumina. The methanol-acetone eluates from the activated alumina were purified by washing with ethyl acetate, by sublimation in vacuo, and by crystallization from a mixture of methanol and ether. Pure crystalline biotin was obtained from the methyl ester by saponification with dilute alkali and acidification of the saponification mixture with HCl. The yield, based on the biotin concentrate as source material, was from 25 to 40 percent. The method is suitable for the preparation of relatively large amounts of biotin.

The effect of certain reagents on the activity of biotin, G. B. BROWN and V. DU VIGNEAUD. (Cornell Univ.). (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 85–89).—Most of the tests were carried out on a crystalline biotin prepared as noted above, using 1- or 2-cc. aliquots of a standard solution containing 12.5 γ per cubic centimeter. The solution was evaporated to dryness, and the reagent added. The reaction mixture, after neutralization and dilution to volume, was tested for biotin activity by the effect on yeast growth. The tests indicated that biotin can be inactivated by vigorous treatment with acid or alkali and by many reagents known to react with α -amino groups, such as nitrous acid, formaldehyde, and chloramine-T; ninhydrin, however, did not affect the activity, and this is interpreted to suggest that biotin is not an α -amino acid. The activity of the biotin was not destroyed by the use of acylating or alkylating reagents. Carbonyl reagents brought about no inactivation, thus indicating the absence of an aldehyde or ketone. Prolonged aeration with air or O_2 had no appreciable effect, but stronger oxidizing agents (H_2O_2 , bromine water) quickly destroyed the activity.

Characterization of the functional groups of biotin, K. HOFMANN, D. B. MELVILLE, and V. DU VIGNEAUD. (Cornell Univ.). (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 207–214, fig. 1).—In continuation of work to determine the chemical nature of the active groups of biotin, evidence was obtained that biotin is a carboxylic acid containing an N,N'-disubstituted cyclic urea grouping and possessing sulfur in a thio ether linkage. By alkaline treatment of biotin, a sulfur-containing diaminocarboxylic acid containing 1 less carbon atom and 1 less

oxygen atom was formed. By oxidation of the biotin with H_2O_2 , a sulfone of biotin was prepared. Various derivatives of these compounds were prepared.

A microbiological assay for biotin, G. M. SHULL, B. L. HUTCHINGS, and W. H. PETERSON. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 913-920, fig. 1).—The present method is based on the fact that under proper conditions the titratable acidity produced by *Lactobacillus casei* is a function of the quantity of biotin in the solution. Since the final determination is titrimetric rather than turbidimetric, colored and turbid solutions can be assayed satisfactorily by the method. Stock cultures are prepared and maintained as they are for the use of this organism in the assay of riboflavin by the method of Snell and Strong (E. S. R., 82, p. 587) and of pantothenic acid by the method of Pennington et al. (E. S. R., 85, p. 442). According to the procedure described, the solutions to be assayed or the biotin for the standard curve, prepared by hydrolyzing the methyl ester as described by du Vigneaud et al. (see p. 625), are added to standard tubes containing 5 cc. of the biotin-free basal medium (containing riboflavin and pantothenic acid and other constituents essential for the organism) adjusted to pH 5.6. After adjustment to 10-cc. volume the tubes are plugged, autoclaved, cooled, inoculated, and incubated for 3 days at 37° [C.]. After incubation the contents of each tube are titrated with 0.1 N NaOH, using phenol red or bromothymol blue as indicator. The range of biotin used for the calibration curve is from 40 to 1,000 $\mu\text{g.}$ per tube. The samples to be run are diluted so that their titers do not come at the extremities of the curve, since these give anomalous results. Data showing the recovery of biotin added to different natural products indicate an accuracy of ± 10 percent for the method. Values are reported for the biotin content of a number of biological materials, including several foodstuffs.

A colorimetric oxidation-reduction method for the determination of the K vitamins, J. V. SCURR and R. P. BUHS (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 451-464, figs. 3).—The method presented in detail "involves a catalytic reduction of the quinone in butanol solution in the presence of phenosafranine as the indicator. The resulting vitamin hydroquinone is then treated with an excess of a butanol solution of 2,6-dichloroindophenol in the absence of air. The diminution in the color of the indophenol is a measure of the quinone originally present." Raney's nickel serves as the catalyst. The test is carried out in butanol solution, since this increases the stability and spectral purity and doubles the optical density of the 2,6-dichloroindophenol reagent. In analyses of natural materials the vitamin K_1 is extracted with petroleum ether, thus eliminating interfering sugars, thiols, ascorbic acid, and other reducing substances not soluble in petroleum ether. Claisen's alkali (KOH in methanol), added after the catalytic reduction, dissolves the hydroquinone, and the addition of water to the ether-washed alkali hydrolyzes the potassium salts of the hydroquinone. The addition of petroleum ether at this stage serves to extract the vitamin K_1 hydroquinone, while other hydroquinones, including that formed from 2-methyl-1,4-naphthoquinone, remain in the alkaline phase. Readings taken 3 min. after the indophenol reagent is added to the extracted hydroquinone are representative of the reducing activity of vitamin K_1 hydroquinone. The more slowly reducing tocopherylhydroquinones do not interfere in this time interval, since they reach their maximum reducing effect only after from 40 to 60 min. Readings taken after this latter interval serve to give a quantitative measure of the tocopherylquinones and tocopherols.

Changes in flour during storage: Temperature and grade determine storage qualities of flour, J. E. GREAVES (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 2, pp. 4, 7).—Analytical studies of flours stored in 50-lb. sacks for

3 yr. indicated that low-grade flours reach their optimum baking properties more quickly and deteriorate more rapidly than do high-grade patent flours, and that relatively high temperature of storage also accelerates both the attainment and the loss of optimum baking quality. Analytical findings with reference to ash constituents and other components of the flours are given.

A method of "fingerprinting" North Dakota wheat flours in respect to their baking strength, R. H. HARRIS, L. D. SIBBITT, and O. BANASIK (*North Dakota Sta. Bimo. Bul.*, 4 (1942), No. 5, pp. 2-5, figs. 5).—From properties of the remixing curves obtained by means of a recording micro dough mixer on remixing, fermented doughs the authors were able to elaborate a mathematical expression predicting loaf volume with an error within the experimental error of duplicate bakings. It is believed probable that such determinations can replace some of the experimental baking tests on hard red spring wheat flours.

Growing sorghum and making sorghum sirup, C. A. HELM and R. BEASLEY (*Missouri Sta. Cir.* 235 (1942), pp. 7, figs. 3).—Very brief introductory statements concerning choice of variety and soil, seedbed preparation, planting, harvesting, and yield are followed by an outline of the process of sorghum sirup making, accompanied by drawings indicating the equipment needed and its lay-out in the form of a hillside plant in which all movement of the juice and sirup is by gravity.

Chromatographic adsorption analysis, H. H. STRAIN (*New York: Interscience Pubs., Inc.*, 1942, pp. X+222, [pl. 1], figs. 37).—The author stresses mainly the methodology, but includes many specific instances of results given by the chromatographic method. A rather extensive bibliography is appended. The chapter headings are historical introduction, applications of chromatographic adsorption methods, apparatus and procedure, adsorbents, solvents and eluants, location of colorless adsorbed substances, chromatography of inorganic compounds, chromatography of organic compounds, and industrial uses.

Technic for photographing early cleavage stages of the hen's egg, M. W. OLSEN. (Univ. Md.). (*Stain Technol.*, 17 (1942), No. 2, pp. 69-71, figs. 2).—A method involving staining with a gentian violet (defined as a methyl violet 2B) greatly improved the clearness with which the blastodisc could be photographed.

A note on fine needles for dissection, H. G. CANNON (*Jour. Roy. Micros. Soc.*, 61 (1941), No. 1-2, pp. 58-59, fig. 1).—The tip of the fine tungsten wire of which the needles are made is dipped into fused sodium nitrate, in which the tip of the wire burns away with incandescence in from a fraction of a second (when the diameter of the wire is 0.05 mm.) to 1 or 2 sec. (when the diameter of the wire is 0.5 mm.) to leave a perfect needle point. The wire is then mounted in the end of a short piece of nickel tubing (bore of 0.2 mm.), and this in turn is set into the end of a brass handle drilled to receive it and made to fit the microdissector.

An inexpensive apparatus for cutting tissue sections on the sliding microtome by the "dry ice" method, M. V. ANDERS (*Stain Technol.*, 17 (1942), No. 2, pp. 85-87, figs. 2).—A small screw-top tin is adapted for this purpose by coating heavily the bottom of the tin (which is to serve as the freezing surface) with solder, embedding an additional piece of tin plate in the reinforced surface and scoring this added tin plate to form a suitable freezing surface, and providing a simple screw plunger by soldering a nut over a central hole in the lid of the tin of a size such that it will pass the corresponding screw. A stove bolt $1\frac{1}{2}$ in. in length is used as the screw plunger, a piece of tin plate or a cork being attached to provide a surface to press the dry ice up under the freezing surface. A tin $1\frac{1}{4}$ in. in diameter, the size used by the author, may be

attached to the microtome through a 2-in. angle iron, one arm of which is bent about the tin to fit snugly and is soldered in place.

Improved paraffin schedules for plant tissues, T. E. RAWLINS and W. N. TAKAHASHI. (Univ. Calif.). (*Stain Technol.*, 16 (1941), No. 1, pp. 7-8).—The first stage of dehydration in each of the two schedules reported upon consists in placing the tissue in 10 percent glycerol containing 1 cc. per 100 of a 10-percent alcoholic solution of thymol and allowing about 10 to 13 days for evaporation of the water. The tissue is then passed through 1:3, 1:1, and 3:1 mixtures of normal butyl alcohol with glycerol, 24 hr. in each, and through four changes of pure normal butyl alcohol warmed on the paraffin oven. Schedule A then calls for paraffin infiltration from the butyl alcohol, whereas schedule B places the tissue in a 3:1 mixture of this alcohol with cedar oil (clearing grade), evaporates the butyl alcohol from this mixture on the oven, and passes to pure paraffin through 25-, 50-, and 75-percent paraffin solutions in the cedar oil, the first on the oven, the second and third in the paraffin oven. Schedule B usually causes less distortion than A, but staining is not so bright as after A. Either schedule caused less distortion than do those commonly used.

A simple method of transferring tissues, M. W. OLSEN. (Md. Expt. Sta.). (*Stain Technol.*, 17 (1942), No. 2, pp. 73-74, fig. 1).—The tissue carrier shown consists essentially of a perforated metal plate $3\frac{1}{2}$ in. in diameter to which are soldered 35 perforated circular metal bands each $\frac{1}{2}$ in. in diameter and $\frac{1}{4}$ in. deep. Both base plate and bands were made from 30-gage monel metal, having at least 225 perforations per square inch. Other metals can be substituted for the monel but should be plated with a noncorrosible metal.

Two convenient washing devices for tissues and slides, G. H. MICKY and H. TEAS. (La. State Univ.). (*Stain Technol.*, 17 (1942), No. 2, pp. 65-68, figs. 4).—A row of five glass tubes is simply supported over a $5\frac{1}{2}$ - by 10-in. pan, the tops of the tubes being open and the lower ends covered with bolting cloth or cheesecloth. A metal tube longitudinally placed over the row of washing tubes and provided with several small openings over each washing tube distributes wash water to the tubes. An extremely simple washing pan for two large racks of slides was made from another baking pan of dimensions the same as those of the one supporting the washing device.

A section-smear method for plant cytology, H. E. WARMEKE (*Stain Technol.*, 16 (1941), No. 1, pp. 9-12, figs. 3).—The procedure recommended is as follows: Kill root tips in Navashin or other fluid containing chromic acid. Wash, dehydrate, embed in paraffin, and section transversely. Stain slides bearing the sections by a Feulgen technic following the modification of De Tomasi, except that the hydrolysis is prolonged to 45 min. and a 10-min. washing in running water is introduced between the fuchsin and the first bath in sulfite solution. Dehydrate and mount in thin Canada balsam, then apply local pressure to top of cover glass with the tip of a scalpel, while observing the action under low power of a microscope. The prolonged hydrolysis softens the tissue and removes sufficient pectic substance so that cells of the section separate readily and may be flattened until the chromosomes come to lie in a single plane. The slide is permanent.

The plastic ethyl methacrylate in routine laboratory technic, M. S. CARBONE and D. J. ZINN (*Stain Technol.*, 17 (1942), No. 2, pp. 75-78).—The use of ethyl methacrylate as a permanent, transparent, colorless medium for mounting in toto invertebrate and vertebrate embryos and small adults is described in working detail. More than 40 species of animals have been satisfactorily treated in this manner.

The rate of penetration of fixatives, P. B. MEDAWAR (*Jour. Roy. Micros. Soc.*, 61 (1941), No. 1-2, pp. 46-57, figs. 9).—Fixatives penetrating into a plasma coagulum (a substance selected as having the same general physicochemical organization as cytoplasm and intercellular fluid) are shown to obey the diffusion laws within the limits of error of the experiments described. The distance penetrated by fixatives is directly proportional to the square root of the time of fixation, or $x = K\sqrt{t}$. Fixatives neither retard nor facilitate their own entry into the coagulum. The relative rates of penetration of a number of simple and mixed fixatives are tabulated. Values of K , the coefficient of penetration when t is expressed in hours and x in millimeters, were found to be as follows for some of the more commonly used components of fixing reagents: Acetic acid 25 percent, 8.816, 8.9 percent, 7.876; formaldehyde 40 percent, 6.722, 8 percent, 5.875; potassium dichromate 2.5 percent, 4.359; mercuric chloride saturated aqueous solution 4.337, 2 percent, 3.466; chromium trioxide ("chromic acid") 1 percent, 3.599, 0.75 percent, 2.992; osmium tetroxide ("osmic acid") 1 percent, 2.977; picric acid saturated solution 2.503; absolute alcohol 1.714; and uranium nitrate 1 percent, 1.362. The author makes note of the fact that "alcohol penetrates curiously slowly."

Amyl acetate as a clearing agent for embryonic material, H. F. DRURY (*Stain Technol.*, 16 (1941), No. 1, pp. 21-22).—Amyl acetate is soluble in 95 percent alcohol and hot paraffin and produces no hardening in objects exposed to its action for prolonged periods. It may be advantageously employed as a general clearing agent and is especially recommended for refractory material. A schedule has proved satisfactory for whole frog embryos and young tadpoles of 45 min. to 1 hr. in 95 percent alcohol, 24 hr. in amyl acetate, rinse in toluene, 15 min. each in three changes of paraffin, imbed. Material so treated may be sectioned at 5μ with comparative ease.

Romanowsky staining with buffered solutions.—III, Extension of the method to Romanowsky stains in general, R. D. LILLIE (*Stain Technol.*, 16 (1941), No. 1, pp. 1-6).—Solutions of 0.3 gm. of various compound dyes of the thiazine eosinate type in 100 cc. of a mixture of equal volumes of methyl alcohol and glycerol gave satisfactory wholesale staining of sections without differentiation when buffered with citric acid and sodium phosphate. Of compound stains of the indicated type, toluidine blue phloxinate was especially useful. Its preparation is described. The reaction should be pH 4.2 for neutral formalin or Orth fixation, pH 4.6 for acid formalin, pH 5.0 for Zenker formalin, and pH 6.5 for ethyl or methyl alcohol or Carnoy fixation.

Synthetic resins of two commercial types are mentioned as mounting media definitely superior to natural Canada balsam but somewhat inferior to liquid petrolatum with regard to fading.

Alizarin red S and toluidine blue for differentiating adult or embryonic bone and cartilage, T. W. WILLIAMS, JR. (*Stain Technol.*, 16 (1941), No. 1, pp. 23-25).—Specimens are fixed in 10 percent formalin, stained 1 week in a solution of 0.25 gm. of toluidine blue in 100 cc. of 70 percent alcohol, macerated from 5 to 7 days in a 2-percent KOH solution, counterstained for 24 hr. in a 0.001-percent solution of alizarin red S in 2 percent aqueous KOH, dehydrated in cello-solve, and cleared in methyl salicylate. In the adult and embryonic forms thus treated, the soft tissues are cleared, while the osseous tissue is stained red, the cartilage blue.

Studies on polychrome methylene blue.—I, Eosinates, their spectra and staining capacity, R. D. LILLIE and M. A. ROZ (*Stain Technol.*, 17 (1942), No. 2, pp. 57-63).—The absorption spectra of eosinates of thiazine dyes in water exhibit absorption maxima at the same spectral locations as do the individual

component dyes in aqueous solution. Commercial samples of Wright's stain showing thiazine absorption maxima between 620 and 660 $m\mu$ generally give satisfactory blood stains. Nuclear staining is redder and cytoplasm grayer blue in 620-640 range, and consequently staining of malaria parasites is less satisfactory in that range. The best malaria stains show their thiazine absorption maxima usually between 650 and 660 $m\mu$. Successive batches of Wright's stain made by the same manufacturer, as well as experimental laboratory lots, may show wide variations in their thiazine absorption maxima and in their staining characteristics.

The reaction of certain stains with bacteria, T. M. McCalla. (Kans. Expt. Sta.). (*Stain Technol.*, 16 (1941), No. 1, pp. 27-32).—The author presents experimental observations supporting the view that staining is an adsorption exchange reaction and is, therefore, more of a chemical than of a physical nature. Displacement of magnesium from cells of *Escherichia coli* and of *Staphylococcus aureus* was shown, as was the replacement of the H ions of hydrogen-saturated cells by crystal violet, safranin, methylene blue, and basic fuchsin in the cells of various organisms. The effect of the acid stain phloxin upon the pH value of a suspension of *E. coli* also supported the author's view of the chemical mechanism of staining reactions.

P-aminodimethylaniline monohydrochloride as an indicator of microbial action on fats, C. H. CASTELL (*Stain Technol.*, 16 (1941), No. 1, pp. 33-36).—The marked changes in the colors of the fat globules in a fat emulsion agar medium inoculated with certain types of micro-organisms were found to result from the increased solubility in fat and fatty acids of this dye as it becomes oxidized. Some of the acids oxidize the dye on contact and therefore color very quickly; fats become colored only when some other agent oxidizes the dye. A table showing the colors in globules of oil that were inoculated with 39 pure cultures of bacteria is included.

Staining bacteria and yeasts with acid dyes, W. E. MANEVAL (Univ. Mo.). (*Stain Technol.*, 16 (1941), No. 1, pp. 13-19).—Acid dyes found satisfactory for the routine staining of bacteria were acid fuchsin, aniline blue w. s., fast acid blue R, fast green FCF, light green, orselline BB, erythrosin, phloxin, and rose bengal. Acid fuchsin, fast green, aniline blue, and orselline are especially recommended. Phenolic solutions of the dyes, acidified with acetic acid, with the addition of ferric chloride to those containing acid fuchsin, aniline blue, fast green, or light green, were used. Staining procedures for a variety of bacteriological purposes are detailed. The principal advantages of acid dyes are better differentiation and less tendency of slime and debris to take the dye.

AGRICULTURAL METEOROLOGY

The quantity of vaporous water in the atmosphere, C. G. ANBOT (*Smithson. Misc. Collect.*, 101 (1942), No. 12, pp. [1]+7).—The applications of a spectrophotometric method, as practiced by the author, to determine how thick a stratum of liquid water would be produced if all the water vapor in the atmosphere could be instantaneously precipitated are described and formulas presented. In this study there was found no general relationship or certain connection between the march of precipitable water from day to day and the fall of rain, and certainly no definite change of precipitable water considerably antedating rainfalls which could serve for forecasting their times and amounts. This is believed to support the view that the approach of a rainstorm is not accompanied by any considerable transport of water from the direction whence the storm comes. What occurs is a traveling disturbance of the atmosphere, which, as it reaches successive

localities, draws together from short distances aqueous vapor already suspended within the atmosphere in those regions. This view is supported by the observation that on the next day following a rainfall the precipitable water is apt to be less than that which usually prevails at that time of the year.

Hail in high and low latitudes, H. LEMONS. (Okla. A. and M. Col.). (*Amer. Met. Soc. Bul.*, 23 (1942), No. 2, pp. 61-68).—The author discusses hail of low latitudes, where it is infrequent, and hail of high latitudes, including Canada and Alaska.

The development and expansion of daily weather forecasting for the Susquehanna River basin, O. L. ROCK (*Pa. Acad. Sci. Proc.*, 15 (1941), pp. 125-128, fig. 1).

Water studies will aid farmers in planning for larger acreages of war-needed crops, H. G. WILM. (U. S. D. A. coop. Colo. Expt. Sta.). (*Colo. Farm Bul.* [Colorado Sta.], 4 (1942), No. 2, pp. 19-20, fig. 1).—Preliminary records taken on a series of plats established in a stand of mature lodgepole pine located on a mountain watershed indicated that the storage of snow during winter increases after timber cutting. Before melting began in 1941 an average of 7.75 in. of water was measured in the snow on the commercially clear-cut areas (10-in. minimum) as compared with 5.33 in. on uncut stands. Both areas became bare of snow at about the same time. Losses of summer rainfall through interception and evaporation from the crowns were found to be rather comparable to the losses of snow during winter.

Indice de variabilidad climatica [Index of climatic variability], W. KNOCHE and V. BORZACOV (*An. Soc. Cient. Argentina*, 133 (1942), No. 4, pp. 279-292).

Indications as to climatic changes from the timberline of Mount Washington, R. F. GRIGGS (*Science*, 95 (1942), No. 2473, pp. 515-519).—An address.

Climatological data for the United States by sections, [January-December 1941] (U. S. Dept. Com., *Weather Bur. Climat. Data*, 28 (1941), Nos. 1-12, [about 225 pp., 2 pls., 8 figs. each]).—These numbers contain the usual brief summaries and detailed tabular statements of climatological data for each State.

Maps of seasonal precipitation percentage of normal by States, fifty-three years, 1886-1938; tables of normals and 10 wettest and 10 driest seasons and years (U. S. Dept. Com., *Weather Bur.*, 1942, pp. [1]+76, figs. 53).

Fruit diseases and the weather in 1941, O. C. BOYD (*Mass. Fruit Growers' Assoc. Rpt.*, 48 (1942), pp. 109-112).—Rainfall and temperature records in Massachusetts for March to October 1941 are presented, and weather conditions in relation to diseases of small fruits, stone fruits, and apple (scab), and to spray injury are briefly discussed.

[Meteorological conditions in the 1940-41 season in Idaho] (*Idaho Sta. Bul.* 244 (1942), pp. 18, 58, 60).—Notes are presented by K. H. W. Klages, R. E. Knight, and W. A. Moss on the high winter temperatures, heavy precipitation, and high variability of climatic conditions at the station and substations.

Proceedings of the Hydrology Conference, held at State College, Pennsylvania, June 30 to July 2, 1941, edited by F. T. MAVIS (*Pa. State Col., School Engin. Tech. Bul.* 27 (1942), pp. VIII+270, figs. 67).—The following papers are included: Scope of the Hydrology Conference, by L. G. Straub (pp. 1-2) (Univ. Minn.); Application of Hydrology in Flood Control, by G. A. Hathaway (pp. 3-40); The Relation of Hydrology to the Third Locks of the Panama Canal, by H. W. Brod (pp. 43-54); An Outline of the Runoff Cycle, by W. G. Hoyt (pp. 57-67); Development of Climatological Records of the United States, M. Bernard (pp. 71-81); Some Aspects of Subsurface Water in Hydrologic Research on Agricultural Watersheds, by H. S. Riesbol

(pp. 85-108) (U. S. D. A.); Looking Ahead at the Weather, by W. F. McDonald (pp. 118-118); Some Aspects of Infiltration in Relation to Runoff, by G. W. Musgrave (pp. 119-134), and The Application of Our Knowledge of the Organic Layers of the Soil Profile to Flood Control, by H. F. Morey (pp. 143-148) (both U. S. D. A.); The Melting Characteristics of Snow and Its Contribution to Runoff, by W. T. Wilson (pp. 153-165); Application of Hydrology to Soil and Water Conservation, by C. E. Ramser (pp. 167-182), and The Measure of Evaporation and Transpiration From Natural Surfaces, by C. W. Thornthwaite (pp. 185-187) (both U. S. D. A.); Laboratory Techniques in the Study of Floods, by H. A. Thomas (pp. 190-212); The Mississippi River Flood Control Model, By K. E. Fields (pp. 213-230); Flood Forecasting in Pennsylvania, by G. Weber, Jr. (pp. 231-249); The Flood of September 1938 at the Big Eau Pleine Dam in Wisconsin, by A. T. Lenz (pp. 255-262) (Univ. Wis.); and Pure and Applied Hydrology—An Integration of Objectives, by L. K. Sherman (pp. 263-267).

Hydrologic data: Blacklands Experimental Watershed, Waco, Texas, 1937-1939 (U. S. Dept. Agr., *Hydrol. Bul.* 2 (1942), pp. IV+197, pls. 2, figs. 44).

Hydrologic data: Central Great Plains Experimental Watershed, Hastings, Nebraska, 1938-40 (U. S. Dept. Agr., *Hydrol. Bul.* 3 (1942), pp. II+148, pls. 2, figs. 13).

SOILS—FERTILIZERS

[Soil investigations by the Idaho Station] (*Idaho Sta. Bul.* 244 (1942), pp. 19, 33-34).—Soil management practices are recommended by G. O. Baker and E. VanSlyke, organic matter was shown by R. S. Snyder and Baker to be important in crop production, and the stage of decomposition of organic matter was shown to influence degree of sorption by clay material. Various factors were found by L. E. Eusminger to affect alkalinity of southern Idaho soils.

[Soil and fertilizer work in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), Nos. 5, p. 2; 6, p. 1).—These two numbers contain the following brief popular articles: No. 5.—Farm Manure: A Crop Worth Caring for, by E. B. Ferris; No. 6.—Phosphate: Costly, Needed, Valuable Plant Food Source, by R. Coleman.

[Soil Survey Reports, 1933 and 1936 Series] (U. S. Dept. Agr., *Bur. Plant Indus., [Soil Survey Rpts.]*, Ser. 1933, No. 37, pp. 99, pls. 3, figs. 3, maps 3; 1936, No. 12, pp. 71, figs. 3, map 1).—These surveys were made in cooperation with the North Dakota and Michigan Experiment Stations, respectively: 1933, No. 37, McKenzie County, N. Dak., M. J. Edwards et al.; and 1936, No. 12, Clinton County, Mich., G. A. Johnsgard et al.

The identification of the clay minerals in five Iowa soils by the thermal method, M. B. RUSSELL and J. L. HADDOCK. (Iowa Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 90-94, figs. 2).—Thermal curves for several pure clay minerals, clay mineral mixtures, and colloids extracted from five Iowa soils were determined by a method devised for use in ceramic technology. The minerals present in the extracted colloids were identified by comparing thermal curves of the colloids with similar curves for pure clay minerals and clay mineral mixtures. All the colloids studied contained high percentages of montmorillonite and a much smaller quantity of kaolinite. The illite content of the soil colloids could not be estimated from the thermal curves but was calculated from the potassium content of the colloids. The prominence of the 225° C. endothermic montmorillonite reaction gave some indication of the degree of base saturation of the

five soils studied. The average estimated percentages of montmorillonite, illite, and kaolinite for the five soils based on the thermal curves, chemical composition, and base exchange capacity data were 60, 30, and 10 percent, respectively.

The thermal method as a quantitative measure of clay mineral content, G. M. SCHAFER and M. B. RUSSELL. (Iowa Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 5, pp. 353-364, figs. 4).—Each of the clay minerals was found to have a characteristic thermal curve, useful for the identification of the mineral. The curve of each mineral can be reproduced readily. There are, however, small variations in the curves of different samples of the same mineral. The thermal curves of montmorillonite are affected by the exchangeable bases present, and it is important to know the base status of a mineral mixture when interpreting its thermal curve. The thermal curves for hydrated halloysite and halloysite were found to have two distinct endothermic reactions occurring at the same temperatures. For each of these minerals the ratio of the areas of the two peaks was found to remain constant for all determinations. The ratio of the areas could be used for determining the area of one peak if the area of the other peak was known. The endothermic peak at 320°-350° C. for these two minerals occurs at the same temperature as does an endothermic peak of gibbsite. The areas of the endothermic peaks of dilutions of the clay minerals with alumina were measured and found to be proportional to the areas of the peaks of the pure minerals. The agreement was particularly good for the sample of montmorillonite used. The areas of the peaks were less reliable for the small samples of kaolinite and hydrated halloysite. Good agreement with the actual amounts present was obtained for the kaolinite-hydrated-halloysite mixture and for montmorillonite in the montmorillonite-kaolinite mixture. Thermal curves of the montmorillonite-hydrated-halloysite mixture were not satisfactory for estimating the amounts present.

Effect of submergence on a Podzol soil profile in the Adirondack forest, T. H. EATON, JR. (Cornell Univ.). (*Soil Sci.* 53 (1942), No. 5, pp. 379-383, fig. 1).—A shallow artificial reservoir about 0.7 mile long and 0.4 mile wide in the Huntington Wildlife Forest Preserve, Newcomb, N. Y., was produced about 1912 by damming. About 1926-28 the wooden dam failed and much of the water went out. The last of the water was let out in 1939.

The occurrence of a typical Podzol profile in an area which had been cleared of all timber and then flooded for 15 yr. is demonstrated from the results of a detailed profile examination, showing a resistance to change in spite of this interference with the normal processes of drainage and leaching, and also showing some special effects of submergence. A diagram shows the Podzol profile below the former lake to be continuous, except for erosion at the beach line, with that of the unaffected forest. In addition to the soil structure observations, counts of arthropods and annelids in the humus layer both of the formerly submerged soil and of the adjacent Adirondack forest soils which had not been submerged were made.

Observations and studies on the peat deposits of Louisiana, W. R. DODSON (*Louisiana Sta. Bul.* 343 (1942), pp. 27, figs. 7).—Because war transportation difficulties have cut off the supply of foreign peat, formerly used extensively in this country for soil improvement, this bulletin brings together the preliminary information on peat resources in Louisiana, with the hope that it may lead to the development of the available resources and stimulate work to learn more about the value of the peat materials of the State. Discussions of the importance and uses of peat and of peat deposits in the United States and in Louisiana are included, as well as a detailed description of the *Sagittaria* peat of the Grand Marais and Lake Tasse areas.

Pressure and streamline distribution in waterlogged land overlying an impervious layer, D. KIRKHAM. (Utah Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 65-68, figs. 7).—The author obtained photographs of streamline flow patterns by placing wire gauze models of tile drains in uniform sand and in stratified soil layers held in tanks having plate-glass fronts at right angles to the drains, the water being colored by potassium dichromate. An impervious layer was placed at various depths below the soil surface. Photographs of flow in models representing various depths and spacings of the drains are reproduced, and their significance is briefly discussed.

Physical and chemical properties of soil profiles of the Scott, Fillmore, Butler, Crete, and Hastings series, H. W. SMITH and H. F. RHOADES (*Nebraska Sta. Res. Bul.* 126 (1942), pp. 43, figs. 10).—A revision of the Grundy and a part of the Scott soils, resulting in the differentiation of the Fillmore, Butler, Crete, and Hastings series, is summarized. Complete profiles were sampled in the new series—1 from the Scott, 2 from the Fillmore, 6 from the Butler, 2 from the Crete, and 1 from the Hastings series. Samples were also taken from the A and upper B horizons of 5 profiles, 1 from the Crete, and 4 from the Butler series. The physical properties determined for the samples from the complete profiles were hygroscopic coefficient, moisture equivalent, lower plastic limit, and liquid limit. Volume weight determinations were made in the horizons of 9 profiles. Liquid limit, hygroscopic coefficient, and moisture equivalent determinations were made for the samples from the 5 shallow profiles. For all samples from the complete profiles, oxidizable material, pH, carbonate content, exchange capacity, and total nitrogen, together with exchangeable calcium and magnesium for noncalcareous samples, were obtained. Exchangeable sodium and potassium were determined for 18 selected samples. Relative humus color was determined for 13 selected samples. The data concerning the physical and chemical characteristics of the soils of the different series were combined to give profiles with a maximum of 6 horizons.

The lack of a clay pan in the Hastings profile was used in the field to differentiate the soils of that series from those of the Crete. The definite character of this separation was apparent from the hygroscopic coefficient, moisture equivalent, liquid limit, plasticity index, and total exchange capacity data for the B horizons of the profiles representing these series. From the laboratory data obtained for soils of the Crete and Butler series, as the latter have recently been mapped in Lancaster County and elsewhere, no line could be drawn separating the two. The suggestion is made that the name Butler is now being applied where Crete should be the preferred series designation. Butler could then be reserved as a name for those soils with a definite sprinkling of gray in the lower topsoil and with a dark grayish-brown pan. This would conform with the original description of soils of the Butler series. Type locations of Butler soils which have this morphology were observed and sampled. Data for the hygroscopic coefficient, moisture equivalent, and liquid limit of these samples support the suggested limitation of the name Butler to soils of these characteristics. In the field, Fillmore soils were separated from those of the Butler series largely on the basis of the presence of iron concretions in the clay pan of the former. Judging from the profiles studied, the authors find that the two could be separated more satisfactorily on the basis of the intensity and thickness of the gray layer. The presence of a gray layer was shown to be correlated with a profile development different from that found when the gray layer has not formed. These differences are shown by the data from the following determinations: Hygroscopic coefficient, moisture equivalent, liquid limit, exchange capacity, pH, and percentage saturation by calcium plus magnesium. The profiles of the Crete,

Butler, and Fillmore series were similar, with the least noncapillary pore space in the clay pan. Among these profiles the Fillmore clay pan had the least such pore space. The Scott profile exhibited a low noncapillary pore space throughout the subsoil. Some new data concerning the gray layer in the A₂ of the Fillmore and Scott series are presented.

The effect of soil texture and slope of land on productivity in two North Dakota counties, W. M. JOHNSON and C. F. BORTFELD (*North Dakota Sta. Bul. 315 (1942), pp. 22, figs. 5*).—Investigations reported in this bulletin were directed to obtain more specific data on the effect of physical characteristics of the land on productivity. A method is explained for determining the effect of a variety of surface soil textures and slope classes on the yield of common crops. Application of the procedure is discussed in relation to selected areas in Pierce and Walsh Counties. Economic factors, such as status of farm operators, assessed valuation, tax delinquency, and mortgage on the different land conditions, are also determined. In both counties the heavy-textured soils were found to be superior to the light-textured soils for most crops, but the authors point out that the highest yields of most crops were not associated with the same texture class in both counties. Slope was found to influence yields of crops in both counties but in different ways and to a smaller degree than texture. Assessed valuations of lands in both counties were closely associated with general productivity level. Mortgage indebtedness data could not be clearly related to other economic data or to soil productivity.

The productive capacity of semiarid soils and the present emergency, W. T. McGEORGE (*Arizona Sta. Bul. 182 (1942), pp. [4]+463-496*).—Restoration of good soil structure and maintenance of maximum productivity require, in Arizona, (1) the use of soil correctives for maintaining freedom from alkali and for reclaiming soils already injured by alkali; (2) the use of animal manures and organic farm waste, returning to the soil as much as possible of the organic material which the soil itself has produced; and (3) the use of soil analysis for developing a program of fertilization. These three phases of the productivity problem are dealt with separately in this bulletin.

The first of the three articles takes up leaching and the use of gypsum, sulfur, and organic matter, and combination methods of reclamation. The usual reclamation methods are discussed, with special emphasis on the structure as more important than the complete removal of salinity or alkalinity and on the use of sulfur or sulfur and gypsum with organic mulching materials. The second article is concerned with the composting methods best adapted for use in semiarid areas. The third article discusses the relation between chemical determinations of the phosphate, nitrogen, and potassium of the soil and its fertility and fertilizer needs. For determining the quantities of these nutrients actually available to plants, the preferred method consists in saturating a suspension of the soil with carbon dioxide and estimating colorimetrically the phosphate, nitrate nitrogen, and potassium of the resulting solution. The importance of establishing correlations between analytical data and fertilizer response by fertilizer experiments on a large number of types is pointed out.

Effect of irrigation waters and cropping on the nutrients and exchangeable bases of desert soils, C. W. BOTKIN and E. C. SMITH (*New Mexico Sta. Bul. 292 (1942), pp. 28, figs. 8*).—The authors report profile studies on the effects of cropping and of the composition of irrigation water on the exchangeable bases and the available nutrients of desert soils under irrigation. The desert soils cropped under irrigation increased somewhat in nitrates and remained at a nitrate level higher than that of the virgin soil, of which the organic matter was normally low. The available soil potassium decreased under cropping, with one

exception, but the potassium level remains high and the irrigation waters supply considerable quantities of this nutrient. There is no indication that cropping will exhaust the potassium supply of any of these soils. Total base exchange capacity was not greatly altered by irrigation and cropping. In general, base exchange capacity varied with the clay content in the soil profile. In certain soils a downward movement of clay was indicated. A ratio of divalent bases (calcium+magnesium) to monovalent bases (sodium+potassium) in the irrigation water of one to one or more was found to result in little change in the exchangeable bases of the soil, whether the concentration of soluble matter in the water was high (3,855 p. p. m.) or low (242 p. p. m.). A ratio of from 0.12 to 1.00 resulted in a considerable increase in exchangeable sodium in a soil that had been under irrigation for 25 yr., although the water had a low concentration of soluble matter and the soil contained a high percentage of calcium carbonate. It is believed that under less favorable conditions the soil would probably have been seriously injured. The desert soils studied were found comparatively high in exchangeable calcium, magnesium, and potassium and to have an unexpectedly high level of available nutrients after from 25 to 40 yr. of cropping under irrigation. The waters of the major irrigation projects were found to have a balance of bases favorable to continued tilth and fertility. All of these conditions favor the permanency of agriculture under irrigation.

The application of delignifying procedures to soil organic matter, A. G. NORMAN and J. E. MOODY. (Iowa Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 171-176, fig. 1).—The effect of a number of delignifying procedures upon the organic matter of surface samples of an Ames and a Webster soil was ascertained by the determination of the reduction in organic carbon as determined by the Robinson, McLean, Williams method (E. S. R., 64, p. 312) and change in susceptibility to hypodlite oxidation, determined according to the procedure of Norman and Peery (E. S. R., 85, p. 438).

Although both soils were formed under similar climatic conditions and contained organic matter of approximately the same C:N ratio, distinct differences were apparent, relatable to the nature of the parent vegetation. The organic matter in the Webster soil, prairie-derived, was more resistant to all extracting agents, was less susceptible to oxidation by hypodlite, had a higher exchange capacity, and was biologically less available than that in the Ames. Though the application of delignifying procedures brought about extensive removal of organic carbon, the behavior of the residues indicated that the grouping oxidizable by hypodlite and believed to be a lignin component in many cases remained behind. If, therefore, a major fraction of the organic matter is predominantly lignin-derived, the processes of decomposition reduce its ability to undergo such reactions as normally bring about solution.

The action of some mesophilic bacteria on cellulose, A. G. NORMAN and W. V. BARTHOLOMEW. (Iowa Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 242-247).—Active fermentation of cellulose by aerobic mesophilic bacteria was not accompanied by any evidence of oxidative attack. Uronic groups, if present, seem to be decreased, not increased. Pentosan material associated with the cellulose was preferentially fermented. A polyuronide gum of bacterial origin was obtained from each of the seven organisms studied. The presence of uronic residues in soil may be due in part to synthetically produced polysaccharides of this nature.

* Nitrogen studies on the western Kansas branch experiment stations, H. E. MYERS. (Kans. Expt. Sta. coop. U. S. D. A.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), p. 237).—The trend of the nitrogen content of dry-land soils follows the same general pattern as is characteristic of humid soils. After approximately

40 yr. of cropping, these soils have apparently not reached an equilibrium though the rate of decrease has become progressively slower. Whether the nitrogen level at the equilibrium point will be adequate for maximum crop production cannot be answered on the basis of present information.

Continuous small grains resulted in the smallest loss of nitrogen. The alternate small grain and fallow system caused losses only slightly larger. Alternate row crop and fallow resulted in the lowest nitrogen level, followed closely by continuous row crop and that by rotations including row crops. In a sod area the nitrogen content remained constant over the period studied. Return of organic matter in any form increased the residual soil nitrogen content, even straw effecting a measurable improvement.

Inoculation of soil with *Azotobacter chroococcum*, J. E. GREAVES and L. W. JONES. (Utah Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 3, pp. 229-232).—A typical dry-farm soil free from *Azotobacter* was inoculated with *A. chroococcum*, variously treated with calcium carbonate and organic manure, and kept bare in a greenhouse for 17 yr. and under wheat 2 yr.

During the first 12 yr. of the experiment, inoculated soil when added to a synthetic mannite medium and incubated for 21 days fixed much larger quantities of nitrogen than did uninoculated soil. At the end of 19 yr. all soils had become contaminated with *A. chroococcum* and all fixed approximately the same quantities of nitrogen. The average annual gain of nitrogen per acre-foot varied from 27 to 38 lb. The uninoculated soil became contaminated with *Azotobacter* sometime during the first 12 yr. of the experiment. It cannot be said definitely, therefore, that inoculation of this soil with *Azotobacter* will increase its nitrogen content. There was definite evidence, however, that the addition of organic manure to the soil increased the quantity of nitrogen gained. It is believed that the gain was due primarily to the activities of nonsymbiotic nitrogen-fixing micro-organisms. It is shown that the absence of *Azotobacter* from this soil is not caused by an unfavorable environment.

Methods of observing soil flora and fauna associated with roots, M. B. LINFORD. (Univ. Hawaii). (*Soil Sci.*, 53 (1942), No. 2, pp. 93-103, pls. 3).—Direct observations, at magnifications up to 900 diameters, of organisms associated with roots growing in soil are possible where roots are grown in contact with a glass cover slip. Small seedlings may be grown a few days in observation chambers made by cementing cover slips to glass rings. These chambers are inverted on the microscope stage for examination. Observations of roots of larger plants and over longer periods are possible where cover slips are cemented over openings in the sides of miniature root-observation boxes of the type described earlier by the author (E. S. R., 83, p. 205). Observation is with cooled incident light. This method enables observation and photographic recording of living bacteria, actinomycetes, fungi, protozoa, and nematodes on and about the root. The glass sides of the observation boxes may be stained as contact slides. When processing roots in lactophenol with an appropriate stain, where interest centers in organisms on the root surface, it is recommended that unwashed roots be fixed in formalin acetic alcohol, and that they be processed in lactophenol without washing or with the least washing that will permit observation of the necessary details. In this way many micro-organisms and nematodes that are lost by a preliminary wash are retained among the root hairs or on the root surface. A brief period of staining after the roots are clear brings out surface details while retaining transparency. The use of these methods with roots of four plant species has shown that varied bacteria become numerous in intimate association with very young roots, down to the apical meristem, and that protozoa and microphagous nematodes congregate and multiply here. The view that microbial activity in

the rhizosphere is related chiefly to destruction of senescent cells is shown to be inadequate.

The response of soil micro-organisms to added plant food on major soil types in Indiana (*Indiana Sta. Rpt. 1941, p. 51*).—Studies by J. L. Roberts and F. R. Olson are briefly noted.

Erosion losses of major plant nutrients and organic matter from Collington sandy loam, H. C. KNOBLAUCH, L. KOLODNY, and G. D. BRILL. (N. J. Expt. Stas. and U. S. D. A.). (*Soil Sci., 53 (1942), No. 5, pp. 369-378*).—Soil organic matter and plant nutrient losses from Collington sandy loam used for vegetable production under the conditions of the New Jersey Coastal Plain were reduced by the use of a rye cover crop, as by the application of 20 tons of manure annually, and markedly by both treatments combined. Losses of organic matter and plant nutrients from the check plots, which lost 26,000 lb. of soil from June 12, 1938, to December 31, 1940, were 1,149 lb. of organic matter, 67 of nitrogen, 154 of phosphoric acid (calculated as the anhydride), 515 of potassium oxide, and 141 lb. of calcium oxide. An application of 20 tons of manure per acre each year combined with a rye cover crop reduced soil losses to 7,260 lb., with other losses as follows: 337 lb. organic matter, 19 nitrogen, 40 phosphoric acid, 118 potassium oxide, and 35 lb. of calcium oxide per acre. Average losses of organic matter and plant nutrients from the four treatments showed that 4.20 times as much organic matter, 3.90 times as much nitrogen, 1.52 times as much phosphoric acid, 1.38 times as much potassium oxide, and 2.33 times as much calcium oxide were lost in the eroded material as were present in the plowed layer of Collington sandy loam.

Erosion on Vermont permanent pastures, A. R. MIDGLEY, C. V. PLATH, and J. J. MAYERNIK. (Coop. U. S. D. A.). (*Vermont Sta. Bul. 483 (1942), pp. 15, pls. 4, figs. 3*).—Sheet erosion is not a major factor on Vermont permanent pastures. It is not appreciable even on very steep slopes, provided the vegetation has not been so damaged as to lead to active gullyng. On the lighter soil types even a spare moss and weed cover serves to check the water run-off. The largest water losses occur when accumulated snows thaw. Gullies form somewhat readily on the lighter soil types at points where the turf breaks, because of overgrazing or from other causes, where the vegetative cover is poor. Contour furrows seem to be of little avail with light soil types but may be of some service on the more retentive soils.

These conclusions were drawn from detailed observations throughout the State, from erosion investigation plats on Hartland silt loam of 16-percent slope and on Hartland sandy loam of 27-percent slope, and from run-off and soil loss measurements on Hartland silt loam pasture land of 47-percent slope, as well as on the Woodbridge, Adams, and other soils at lower and higher slope percentages. Very little erosion occurred on pasture lands even of 50-percent or greater slope, except these steep slopes were too heavily grazed. Stream-bank erosion seemed the most serious form of soil loss in Vermont, and much work has already been done to check such bank cutting (E. S. R., 81, p. 339).

Conservation and better land use for Oklahoma, H. A. DANIEL, H. M. ELWELL, and H. F. MURPHY. (Coop. U. S. D. A.). (*Oklahoma Sta. Bul. 257 (1942), pp. 53, figs. 23*).—The most effective method of controlling erosion was with thick-growing vegetation, especially grass. Native prairie grasses reestablish themselves on eroded land slowly, but this process can be greatly accelerated in central Oklahoma by the use of legumes, such as sweetclover and sericea lespedeza heavily fertilized. During the last 3 yr. the production of beef on formerly useless, abandoned, scrubby oak land compared favorably with that on the range land. In comparisons of a livestock system, a grain system, and a commercial fertilizer

system, the best results were obtained when all crops except lint cotton were fed to livestock and the manure produced returned to the land with additional lime and phosphorus. Land submarginal for cultivation may be more stable and capable of greater returns when put to its most desirable use. For arable lands, terracing to conserve both soil and water, together with crop rotation, cultivating on the contour, and conservation of all returnable organic matter constitute the recommended practices.

Save your soil (*U. S. Dept. Agr., Soil Conserv. Serv., Conserv. Folders 1* [1941], pp. [5], *figs.* 2; 2, pp. [5], *figs.* 2; 3, pp. [5], *figs.* 2; 4, pp. [5], *figs.* 2; 5, pp. [5], *figs.* 2; 6, pp. [5], *figs.* 2; 7 [1942], pp. [5], *figs.* 2; 8, pp. [5], *figs.* 2; 9, pp. [5], *figs.* 2; 10, pp. [5], *figs.* 2; 11, pp. [5], *figs.* 2; 12, pp. [5], *figs.* 2; 13, pp. [5], *fig.* 1; 14, pp. [5], *figs.* 2).—A series of folders describing practical methods for the conservation of soil and water for farmers and ranchers of the northern Great Plains on the following subjects: Contour strip cropping saves both soil and water; protected waterways in cultivated fields; wildlife and soil conservation go hand in hand; range improvement by proper stocking; strip cropping for control of wind erosion; save soil, moisture with contour tillage; establishing grass on unproductive cultivated land; stock-water dams in the northern Great Plains; stock-water dugouts an aid to range management; water spreading and flood irrigation; developing springs to furnish water for livestock; tree shelterbelts or windbreaks helpful on the northern Great Plains; protection and care of farm woods; and tree planting to stabilize gullies and stream banks.

Teamwork to save soil and increase production, P. A. WARING (*U. S. Dept. Agr., Misc. Pub. 486* (1942), pp. [66], *figs.* 37).—An illustrated publication showing the development, adoption, and resultant benefits of soil and water conservation practices by a group of farmers in the watershed of Honey Hollow Creek, located in Bucks County, Pa.

Resting the land for future gains, H. R. COX (*New Jersey Stat. Cir. 435* (1942), pp. 16, *figs.* 8).—This circular stresses the value of maintaining or increasing the organic matter or humus content of the soil by (1) growing green-manure crops, (2) applying various organic materials, and (3) conserving crop residues. Green-manure crops, especially winter cover crops, are of value in this territory, particularly in preventing erosion by wind and water. Among organic materials still available are salt hay, peat, pine needles, refuse from wasteland, and mulch materials produced on the farms. Among the crop residues of most importance in maintaining organic matter are sods of grass, clover, and alfalfa. Successful stands of these crops not only furnish the hay and pasture necessary for livestock but their residues have a most favorable effect on the crops following. It is estimated that resting one-fourth of the land under cultivation would require increasing the yield of the remaining three-fourths only by from 10 to 15 percent because of the cost saved in fertilizer, seed, and other expenses, and that more than this increase should be obtainable, raising the total net return while improving the condition of the land.

Effects of soil type and fertilizer treatments on the chemical composition of certain forage and small grain crops, S. C. VANDECAVEYE. (Wash. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 107-119).—The author reviews a large number of papers, mostly from among those published in the last 10 yr. Of the papers dealing with the composition of pasture grass and hay, most attributed low nitrogen and phosphorus content to low soil fertility. Significant differences in composition of legume hays and cereal grains were most often referred to differences in soil texture. The results of 60 investigations indicated that applications of nitrogen fertilizers for pasture grass and hay effect increased percentages of nitrogen in the herbage, occasionally associated with reduced

percentages of phosphorus or calcium, or both, but in some instances with increased percentages of these constituents. Nine of the 31 studies of wheat revealed definite increases in content of nitrogen in the grain, whereas in the other 20 the composition of the grain was not affected unless late or large applications of nitrogen fertilizers were made or were affected irregularly, depending upon soil and other environmental factors. In barley, oats, and corn similar trends were indicated. With one exception, in 29 studies applications of phosphate fertilizers alone or with lime for pasture grass or hay effected an increased phosphorus content in the herbage, and, in the majority, also increased contents of nitrogen or calcium, or both. Similar trends were indicated by the results of the 14 studies pertaining to legumes, but not by the results of the 15 studies pertaining to wheat and barley, as in about 50 percent the phosphorus content in these cereal grains was not affected. Potash fertilizers applied alone or with phosphates for the production of pasture herbage, grass hay, and cereals, as reported by 29 investigators, had an irregular effect upon the mineral constituents of each of these crops. They caused significantly increased percentages of potassium in the herbage, hay, or grain in relatively few instances. The effect of complete fertilizers on the composition of crops varied considerably.

The value of liquid manure as a fertilizer for pasture, R. E. HODGSON, J. C. KNOTT, V. L. MILLER, H. K. MURER, U. S. ASHWORTH, F. B. WOLBERG, and K. BAUR. (Coop. U. S. D. A.). (*Washington Sta. Bul.* 412 (1942), pp. 28, fig. 1).—Liquid manure as used in this investigation consisted of both the solid and liquid excrement voided by cows during the time they were stanchioned in the barn for about 3 hr. twice a day. In order to avoid possible burning injury to the pastures, the total excrement was diluted approximately 10 times with water that was used to wash the milking barns. The excrement was collected and stored in a cement reservoir without a preservative until it was spread on the pasture. The average composition on a fresh basis of the liquid manure for a 4-yr. period was dry matter 2.08 percent, total nitrogen 0.125, ammonia nitrogen 0.076, calcium 0.037, phosphorus 0.014, and potassium 0.130 percent. The experimental plots were located on muck soil of high fertility. Rotational grazing was used, and the liquid manure was applied to each plot of the treated pasture immediately after each grazing. The period between application and grazing varied from 18 to 21 days, and there was no evidence that the palatability of the grass was affected. Liquid manure treatment gave an average yearly increase in yield of total digestible nutrients per acre of 8.3 percent over 5,767 lb. produced on the untreated pasture. Potassium content of the herbage from treated pastures averaged 75.6 percent higher than from untreated areas. The protein content was slightly higher on the treated area. Digestibility coefficients of herbage from the fertilized areas were consistently higher than for forage from the untreated pastures.

The problem of phosphate fertilizers, E. E. DETURK (*Illinois Sta. Bul.* 484 (1942), pp. 541-584, pl. 1, figs. 16).—This publication presents a comprehensive report on phosphate fertilization under Illinois conditions. The phosphorus-supplying power of the soil is reviewed in relation to the different forms of phosphorus found in the soil. The response to phosphorus as measured by yields of corn, oats, wheat, and hay was determined for various areas in the State.

The requirements for phosphorus of the various crops are discussed. Utilization of phosphorus by legumes is illustrated with sweetclover and is contrasted with that of small grains as illustrated by spring wheat. Phosphorus nutrition, requirements at various stages of growth, effect on plant development and maturity, seasonal variations in phosphorus supply of the soil, and deficiency symptoms are presented in detail for corn and wheat. The effect of liming on phosphorus

response is reviewed. The author concludes that both rock phosphate and superphosphate can play an important part in meeting the phosphorus requirement of Illinois soils for the production of maximum yields of major farm crops.

Comparative efficiency of organic phosphorus and of superphosphate in the nutrition of plants, B. R. BERTRAMSON and R. E. STEPHENSON. (Oreg. Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 3, pp. 215-227, pl. 1).—The efficiency as compared with treble superphosphate of the various organic phosphorus fertilizers on acid soils in supplying, in pot tests, the immediate needs of the crop was in the following order: Treble superphosphate=calcium ethyl phosphate>nucleic acid>lecithin>phytin. The ease of decomposition of the organics was apparently in the same order, with the exception of phytin, which was probably precipitated in the soil. Experiments to determine which phosphorus fertilizer was the most efficient in supplying the plants with phosphorus over a long period showed the order of decreasing efficiency as follows: Treble superphosphate=calcium ethyl phosphate>nucleic acid>lecithin for the Aiken soil. The order for Sifton soil was calcium ethyl phosphate=lecithin>water only>nucleic acid=treble superphosphate. The total phosphorus content of the western Oregon soils according to groups was mature valley soils>recent stream-bottom soils>old residual hill soils. The percentage organic of the total phosphorus in these soils by groups was old residual hill soils>mature valley soils>recent stream-bottom soils. In general, the phosphorus fertility or supplying power of these soils was found to be in an order inverse to that of the organic phosphorus percentage of the total phosphorus.

Field test of phosphate fertilizers, C. F. NOLL and C. J. IRVIN (*Pennsylvania Sta. Bul.* 423 (1942), pp. [1]+14, fig. 1).—Supplementing Bulletin 315 (E. S. R., 74, p. 14), this publication covers a 20-yr. field test of superphosphate, rock phosphate, basic slag, and steamed bonemeal with a rotation of corn, wheat, oats, and mixed clover and timothy on Hagerstown silt loam soil. All phosphate carriers were applied with nitrogen and potash, and, in addition, all but bonemeal were used as supplements to manure. Without manure, rock phosphate supplying 144 lb. of phosphoric acid produced slightly better yields than superphosphate supplying 48 lb. of phosphoric acid. When used with manure on limed land, the yields were about the same from both. When 6 tons of manure was supplemented with superphosphate the returns were increased above the cost of the superphosphate by approximately \$1 per ton of manure.

Phosphorus fixation as affected by soil temperature, R. R. ROBINSON. (U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 4, pp. 301-306, fig. 1).—The effect of soil temperature on phosphorus fixation was determined for Dekalb silt loam by using Ladino clover as the indicator crop. Incubating the soil at optimum moisture content for 2 mo. with the temperature fluctuating between 15° and 45° C. resulted in poor plant growth when compared with incubation at a temperature of 3° or with no incubation treatment. Applications of large amounts of phosphorus on soils after incubation at high temperature produced good growth, thereby indicating that the poor growth on untreated soil was due to a decrease in available phosphorus.

The downward movement of lime and superphosphate in relation to permanent pasture fertilization, F. W. SCHALLER. (W. Va. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 162-166, figs. 8).—Determinations of pH and of available phosphate were made at the depths 0-1.5, 1.5-3, 3-5, and 5-7 in. Although most of the lime still remains near the surface, there was found a slow but continuous neutralization in the deeper layers. The movement of lime on plats over a 7- to 8-yr. period was less than that on the plats in operation for 14 yr. When superphosphate was used in addition to lime, the reduction of

acidity was less at all depths. Sodium nitrate caused an additional increase in pH at all depths. Phosphorus from superphosphate remained almost entirely in the surface 1.5 in. There was a slight penetration to 3 in., but almost none below that depth. Increased penetration of phosphorus resulted from an increase in the application of superphosphate and was further facilitated by a lighter soil texture.

Principal Colorado soils conserve lime for war because natural supply is high. D. S. ROMINE and R. GARDNER (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 2, pp. 21-22, fig. 1*).—Most Colorado soils contain sufficient to excessive supplies of lime, the principal agricultural soils being calcareous. Only relatively small areas of podzolic and rough mountainous soils show a lime requirement, and these lands are largely unsuitable for cultivation.

Liming Iowa soils. B. J. FIRKINS (*Iowa Sta. Bul. P45, n. ser. (1942), pp. 469-484, figs. 3*).—Iowa soils, once well supplied with lime, are gradually increasing in acidity because of losses from leaching, erosion, decomposition processes, removal by crops, and the sale of livestock products. Over 75 percent of the soils of the State are estimated to require lime for the efficient production of alfalfa, sweetclover, red clover, and other legumes. A practical discussion is presented on the benefits of lime from the plant and soil standpoint, and data are also given on the tolerance of various common plants to soil acidity. Methods of obtaining soil samples for determining the amount of lime to apply, sources of liming materials, factors governing the value of different liming materials, rates and time of application, and methods of distribution are given.

Adsorption of barium and hydroxyl ions by soils and minerals in relation to pH. A. MEHLICH. (N. C. Expt. Sta.). (*Soil Sci., 53 (1942), No. 2, pp. 115-124, figs. 3*).—Adsorption of barium by soils and several minerals reached a maximum at the point of neutralization of the exchangeable hydrogen. The reaction at which this occurred was about pH 6.0 for humic acid, 6.8 for peat, 7.9 for Eutaw, 8.2 for Norfolk, 8.1 for bentonite, 8.3 for chabasite, 8.7 for pyrophyllite, and pH 9.6 for kaolin. Above these pH values both barium and hydroxyl ions were adsorbed in increasing and essentially equivalent amounts. Maximum adsorption of barium by permutite, halloysite indianait, silica, and lignite was not measurable. Equivalent adsorption of barium and hydroxyl ions by these materials occurred above pH 5.2 for lignite, 7.6 for indianait, 7.9 for silica, and pH 8.7 for permutite. It is concluded that the method consisting of barium chloride buffered at pH 8.2 with triethanolamine (E. S. R., 86, p. 731) should yield maximum values for base-exchange capacity and exchangeable hydrogen for most agricultural soils.

The importance of sodium for plant nutrition.—III, The equilibrium of cations in the beet. J. J. LEHR (*Soil Sci., 53 (1942), No. 5, pp. 399-411, figs. 4*).—In experiments carried out in extension of work previously noted (E. S. R., 87, p. 29), fodder beets were grown on an artificial soil, the composition of the adsorption complex of which could be regulated arbitrarily. The artificial soil consisted of a carbon of high adsorptive capacity for cations, about 90 percent saturated with calcium, magnesium, potassium, or sodium ions, and mixed with sand to provide the desired total basic ion content and proportion of each ion. The equilibrium of ions in the beet, dominated largely by the ions potassium, sodium, and calcium, was correlated graphically with the production. The results indicate that foliage and root react differently to the proportion of ions in the soil. In the equilibrium of ions in the foliage sodium plays a very important part; in the equilibrium of ions in the root potassium is very important. Sodium can replace potassium to a large extent, however, in the beet root without detriment to good production and is, under all circumstances, an important fac-

tor in the equilibrium of ions. Good yields with no available sodium present could not be obtained. Calcium, on the contrary, when present in relatively large quantities, very soon has a detrimental effect on the production of both foliage and root. For practical beet culture sodium should, therefore, be preferred as the secondary ion in fertilizers. It has a potassium-conserving effect.

Effects of aluminum on copper toxicity, as revealed by solution-culture and spectrographic studies of citrus, G. F. LIEBIG, JR., A. P. VANSELOW, and H. D. CHAPMAN. (Calif. Citrus Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 5, pp. 341-351, figs. 5).—An apparently stimulating effect of aluminum on citrus growth was shown to be due to the antagonistic effect of aluminum on copper. In the absence of aluminum, 0.1 p. p. m. copper was decidedly toxic to Valencia orange and lemon cuttings. The addition of 0.1 p. p. m. aluminum to cultures injured by such a concentration of copper was sufficient to offset this toxicity. The addition of 0.1 p. p. m. aluminum to purified nutrient solutions containing only a trace of copper and other micronutrients slightly depressed plant growth. The addition of from 2.5 to 5 p. p. m. aluminum to purified base nutrient solutions greatly stimulated root development but depressed top growth. Lower concentrations of aluminum, i. e., 0.1 and 0.5 p. p. m., did not produce this effect. Spectrographic analyses of various parts of lemon cuttings grown in solution cultures containing different concentrations of aluminum and copper indicated that the detoxifying influence of aluminum on copper is exerted in the roots. Aluminum did not prevent the absorption of copper by the roots but did, in some manner, prevent injury by this element. In the absence of aluminum, excessive copper caused a brownish appearance in citrus roots and short, swollen laterals which give the roots a dwarfed, knotty, and unhealthy appearance. Subsequent top growth commonly exhibited iron chlorosis.

Field studies on methods for determining availability of selenium to plants, O. E. OLSON, D. F. JORNLIN, and A. L. MOXON. (S. Dak. Expt. Sta.). (*Soil Sci.*, 53 (1942), No. 5, pp. 365-368).—In naturally seleniferous soils no correlation between the selenium content of *Agropyron smithi* and the total, water-soluble, or base-soluble selenium content of the surface foot of the soil in which it grew could be found. Soils in which the leaching of selenium was apparently the greatest seemed to produce plants of the highest selenium contents, and it appeared that much selenium is absorbed from the subsurface soils. The analysis of the plants growing in a soil seemed to be the most practicable method of determining the "available" selenium in the soil.

Inspection of fertilizers, E. J. DESZYCK and R. W. GILBERT (*Rhode Island Sta. Ann. Fert. Cir.*, 1942, pp. 19).—In addition to the presentation for the 1941 season of the inspection analysis data, this circular points out that the use of inert fillers in fertilizer mixtures involves transportation of filler which "may be equivalent to a 100-mile movement of 31,000 freight cars. Its handling may approximate the full working time of 1,000 men." The consumer is held guilty of a large share of the blame for this waste in maintaining a demand for mixtures containing unnecessary diluents.

AGRICULTURAL BOTANY

Drug plants native to Great Britain, W. O. JAMES (*Nature [London]*, 148 (1941), No. 3747, pp. 217-218).—"Apart from herbalist simples, there are some half-dozen or so plants of Europe and the British Isles which yield drugs of first-class medical importance." These are discussed as to phases related to war shortages, including collection of wild plants, cultivation, and processing.

The identification and characterization of bacteriophages with the electron microscope, S. E. LURIA and T. F. ANDERSON (*Natl. Acad. Sci. Proc.*, 28

(1942), No. 4, pp. 127-130, pls. 2).—The morphology and particle diameter are presented and illustrated for two bacteriophages active against *Escherichia coli* and one against a staphylococcus. The extreme interest is pointed out of the finding of such constant and relatively elaborate structural differentiation in objects of supposedly macromolecular nature, and the significance of the results is briefly discussed.

Use of complete fertilizers in cultivation of microorganisms, V. L. LOOSANOFF and J. B. ENGLE (*Science*, 95 (1942), No. 2471, pp. 487-488).—Sometimes experimental work requires the use of very large amounts of a culture containing micro-organisms, as in the growing of phytoplankton for studies on the physiology of feeding of oysters. Of a large number of commercial fertilizer mixtures tried for this purpose, several gave excellent results. In outdoor tanks of several thousand gallons capacity, *Chlorella*, *Nitzschia*, *Proocentrum*, and many other micro-organisms (including chlorophyll-bearing and colorless flagellates) grew exceptionally well, and ciliates produced good cultures. It is believed that this method may prove especially useful at this time when the ordinary media are difficult to obtain.

Secondary spores in the mycelium of the cultivated mushroom, *Psalliota campestris* Fr., A. M. KLIGMAN. (Pa. State Col. et al.). (*Amer. Jour. Bot.*, 29 (1942), No. 4, pp. 304-308, figs. 9).—Chlamydosporelike cells are described for varieties and races of *P. campestris*.

The Polyporaceae of Pennsylvania.—III, The genus *Poria*, L. O. OVERHOLTS (*Pennsylvania Sta. Bul.* 418 (1942), pp. 64).—Continuing this taxonomic series (E. S. R., 74, p. 48), 60 species of *Poria* (8 new) are here considered. Included are an index to the species, a tabulated arrangement under the 3 sections of the genus, and a key to the species. This study is preparatory to a monographic treatment of the species of the genus in the United States and Canada.

Vitamin deficiencies of the filamentous fungi, W. J. ROBBINS and V. KAVANAGH (*Bot. Rev.*, 8 (1942), No. 7, pp. 411-471).—It is now well recognized that the growth of many fungi is determined by the presence or absence in the medium of vitamins or their components or derivatives. The subject is of fundamental significance not only to the culturing of specific fungi but also to our knowledge of vitamins and to a clear understanding of the basic factors concerned in the development of all organisms. Because of the ease and convenience with which they may be cultivated, fungi may afford information on vitamins more quickly than can be obtained with experimental animals. In this analytical review the authors summarize the literature (147 references) on the relations of vitamins to the growth of specific fungi, including those which have been reported to grow poorly or not at all in solutions limited to minerals, sugar, and a nitrogen source. The name of each fungus (approximately 400 entries, alphabetically arranged) is given with the general composition of the basal medium used and the effect on development of the fungus of the addition of natural extracts or pure vitamins.

The effect of vitamins on ten strains of *Saccharomyces cerevisiae*, L. H. LEONIAN and V. G. LILLY. (W. Va. Expt. Sta.). (*Amer. Jour. Bot.*, 29 (1942), No. 6, pp. 459-464).—Singly and in all combinations, 5 growth substances were tested on 10 strains of this yeast. After 72 hours' incubation at 25° C., 4 strains proved dependent on inositol and only 1 on thiamin, all 10 were greatly restricted in growth with pantothenic acid omitted, and no growth occurred when biotin alone was left out. None of the strains were affected by lack of pyridoxin, but when thiamin and pyridoxin or thiamin and inositol were omitted some were reduced in growth, though they were unaffected when these substances were left

out one at a time. Some strains were unable to produce optimum growth when only two growth factors were present, some required three, and others four. With the incubation period reduced to 48 hr., a number of strains became dependent on one or more growth factors which did not appear necessary with the 72-hr. period. Often the amount of inoculum controlled growth, but in other cases it apparently did not.

Hypoxanthine, a growth substance for Phycomyces, W. J. ROBBINS and F. KAVANAGH (*Natl. Acad. Sci. Proc.*, 28 (1942), No. 3, pp. 65-69, fig. 1).—The unidentified growth substance previously referred to as factor Z₄ (E. S. R., 87, p. 194) is here identified as hypoxanthine and the study discussed in detail.

Effect of the vapor of the methyl ester of α -naphthaleneacetic acid on the sprouting and the sugar content of potato tubers, F. E. DENNY, J. D. GUTHRIE, and N. C. THORNTON (*Contrib. Boyce Thompson Inst.*, 12 (1942), No. 4, pp. 253-268, fig. 1).—When this ester was incorporated into filter papers distributed among potato tubers in glazed earthenware containers, sprouting was inhibited. With as much as 400 mg. per 1 kg. of tubers, sprouting was prevented for at least 1 yr. from harvest, but with 100 mg. some sprout development occurred after 6-8 mo. Sprouting was definitely retarded by 30 mg., and the lower limit under test conditions was about 10 mg. The impregnated filter papers, after storage with tubers for several months in closed but not entirely sealed containers, were still effective when used on a second lot. Applied for 10 days to a month, a definite retardation of sprout development was obtained, but the inhibition was incomplete and the result after 3-8 mo. was much less marked than that under continuous treatment. There was neither shrinkage nor sprouting of tubers stored under this ester treatment at 10° C. Sprouting was inhibited satisfactorily at 15° for at least 8 mo. and at 18° for 3-6 mo., but in each case there was some shrinkage. The treatment appeared to have no definite effects on the sugar content of the juice of the tubers, but it permitted them to be stored at temperatures sufficiently high to maintain low values for reducing sugar content and so to furnish potato chips of satisfactory color. However, because of lack of information as to the toxicity of the chemical, no recommendations are as yet given for use of the method with tubers destined to be used as food.

Inactivation of the browning system in frozen-stored fruit tissue, F. E. DENNY (*Contrib. Boyce Thompson Inst.*, 12 (1942), No. 4, pp. 309-320, figs. 3).—After peeling, coring, or pitting, tissues of peach, pear, and apple fruits dipped in dilute solutions of thiourea and then frozen in a cold room at -6° to -10° C. could be stored for many months or even more than a year without browning. Furthermore, tissue so treated did not turn brown when thawed and exposed to the air, or even after it had been thoroughly leached with water for 20-24 hr. to remove the thiourea. Only a short storage period was needed to inactivate the browning system in the treated tissue. A method was also developed for obtaining and holding apple tissue in the frozen state without browning or thiourea treatment, but such tissue browned on thawing and exposure to the air. Thus it is clear that the conditions during the freezing period were not such as to cause inactivation of the browning system in the absence of thiourea, and that thiourea by its presence caused a loss of the capacity of the tissue to turn brown.

Additional studies regarding the cation absorption mechanism of plants in soil, R. OVERSTREET, T. C. BROYER, T. L. ISAACS, and C. C. DELWICHE. (Univ. Calif.). (*Amer. Jour. Bot.*, 29 (1942), No. 3, pp. 227-231, figs. 2).—With flowing KCl culture solutions containing radioactive K, a determination of the influence of concentration on the rate of K absorption by barley roots was made for very short intervals, and an approximate value for the maximum absorption rate per unit area of root surface was calculated for the more active regions of the

tissue. A determination was also made of the magnitude of the CO_2 liberation by absorbing roots in K-bentonite suspensions as a function of time. The relationship between organic acid synthesis by roots and ion absorption from K-bentonite suspensions and K salt solutions was investigated, and it is concluded that CO_2 , if involved at all, must play an intermediate role in cation absorption from clay suspensions. Proposed mechanisms for cation absorption by roots in soil and clay suspensions are discussed. See also a previous note by Hoagland and Broyer (E. S. R., 76, p. 457).

Effects of Ca and other divalent ions on the accumulation of monovalent ions by barley root cells, F. G. VIETS, JR. (Univ. Calif.). (*Science*, 95 (1942), No. 2471, pp. 486-487).—The results of tests reported suggest the possibility that Ca and kindred cations can increase the permeability of the plasma membrane to K and Br during concurrent salt accumulation.

The relation of zinc to seed production, H. S. REED. (Calif. Expt. Sta.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 11, pp. 635-644, figs. 2).—Though the amounts necessary were small, Zn proved essential for both vegetative and reproductive processes in peas, beans, and milo. Peas and beans furnished with suboptimum quantities of Zn may make appreciable vegetative development without forming seeds, and if pods are formed they are usually seedless. A definite threshold concentration of Zn necessary for seed production was shown by plants grown in nutrient solutions. As to viability, small peas from plants receiving concentrations close to the threshold values were as good as larger seeds from superior plants. The amounts of Zn, although suboptimum, may nevertheless be responsible for the formation of sufficient stored auxin to insure development of the embryonic plants. There are 15 references.

Reserve foods in the roots of whiteweed (*Cardaria draba* var. *repens*), C. G. BARR. (Colo. Expt. Sta. coop. U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 12, pp. 725-740, figs. 8).—Data showing the seasonal trend of carbohydrates in both noncultivated and cultivated plats are presented. Samples collected at 2-week intervals from April 25 to October 29 from noncultivated plats indicated a maximum accumulation of carbohydrates about August 1, and the lowest content was found early when sampling was started. The total sugar content was higher in roots from the second foot of soil than in those from the first-foot level until about mid-September. Root reserves were present chiefly as starch. The starch content of undisturbed plants reached a maximum of over 21 percent fresh weight, but the total sugar content never exceeded 7.44 percent and reducing sugars remained uniformly low, reaching a maximum of 1.41 percent. Clean cultivation held the starch content to about 4.5 percent and total sugars to less than 3.5 percent. Both soluble and colloidal N decreased during vegetative growth and showed a slight but apparent increase after flowering. Samples collected at 4-day intervals during 24 days after a single cultivation showed no material change in carbohydrate reserves until about 14-16 days after cultivation, after which there was an appreciable accumulation. Sodium chlorate treatment for controlling whiteweed was not increased in effectiveness by an early season cultivation. Biweekly cultivations proved as effective as weekly cultivations in reducing the root reserves and in controlling the weed.

Presence of anti-hemorrhagic material in roots of European bindweed (*Convolvulus arvensis* L.), A. L. BAKKE and N. D. RENDER. (Iowa Expt. Sta. coop. U. S. D. A. et al.). (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 353-354).—A substance (or substances) was found which causes clotting in human blood.

Physiology of rotenone crops (*Puerto Rico Sta. Rpt.* 1940, pp. 43-44, 45, 46, figs. 2).—Data are presented on factors influencing elaboration of rotenoids, the effects of weather cycles on the tissue patterns of *Derris* grown in Puerto

Rico, root diameter as an unreliable indicator of rotenoid content, and *Derris* from the Far East showing tissue patterns similar to those of locally grown roots.

The process of amino acid formation from sugars in *Aspergillus niger*, R. A. STEINBERG. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 11, pp. 615-633).—"Carbon utilization factors (grams of yield per gram of carbon supply) for about 120 compounds, obtained with *A. niger* Van Tiegh. grown for 4 days at 35° C., were as follows: D-glucose, 1.43; D-mannose, 1.46; D-fructose, 1.88; L-sorbose, 1.26; and D-xylose, 1.09. Other compounds were poor sources of carbon supply. Enolization was not a factor in sugar utilization. All pentoses and hexoses having an L-3-carbon atom and a D-4-carbon atom were assimilable, except the epimers of D-xylose and probably L-sorbose. Preliminary oxidation to α -keto acid derivatives and decarboxylation appeared necessary for assimilation of hexoses. The hypothesis was proposed that the aldehyde derivative of L- α , β -dihydroxy *n*-valeric acid served as precursor for amino acid formation. D-4-carbon of the monoses became L- α -amino carbon in the amino acids, and L-3-carbon remained unchanged to become *d*- β -hydroxy in *d*(-)-threonine, and possibly in hydroxyglutamic acid and hydroxyproline also. The primary amino acids formed were probably proline, glutamic acid, and ornithine—all α , δ -derivatives of *n*-valeric acid—since mixtures of these attained a carbon utilization factor of 0.83 as compared to 1.17 with sucrose. Evidence was obtained that the carbon utilization factor for amino acid mixtures was increased by substitution of the corresponding hydroxy acids. Growth requirements for trace elements with assimilable sugars showed little difference, except that cultures on D-xylose from which iron had apparently been removed by treatment with calcium carbonate gave exceptionally high yields. Trace-element requirements with monoses were quite similar to those with sucrose." There are 17 references.

Reversions in morphology of nitrite-induced "mutants" of *Aspergillus niger* grown on amino acids, R. A. STEINBERG and C. THOM. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 11, pp. 645-652).—Morphological reversion to the original strain occurred in a nitrite-induced injury-mutant of *Aspergillus niger* when grown on lysine, cystine, β -phenyl- β -alanine, threonine, and valine; or in admixture with lysine, on arginine, aspartic acid, histidine, tyrosine, or valine. A mixture of nicotinic acid, lysine, and valine gave best results. A nitrite-induced injury-variant of *A. amstelodami* gave complete morphological reversion to the original strain only with a mixture of lysine and threonine. Assimilability of amino acids did not appear to be a major factor in these responses. Comparison of the capacities for amino acid utilization between the standard strain and each of two variants of *A. niger* disclosed alterations proportional to the extent of morphological change. These changed assimilation capacities did not destroy the general nature of the responses characteristic of the original strain, though individual amino acids were affected. The variant having the greater morphological alterations exhibited much less capacity for assimilating the fully plastic acids (aspartic acid, glutamic acid, and proline) and increased capacity for utilizing the aplastic acids (cystine, histidine, lysine, norleucine, and tyrosine). Utilization of hydroxyproline had become particularly poor in the almost sterile or more atypical variant. Enzyme suppression with nitrite disturbed the cell maturation as in abnormal cells produced in animals by carcinogenic compounds.

The growth and metabolism of oat seedlings after seed exposure to oxygen, H. G. ALBAUM, J. DONNELLY, and S. KORKEKES (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 388-395, figs. 8).—When oats grains were oxygenated during the soaking period, subsequent growth was almost completely inhibited as compared to aerated

controls. Assays 80 hr. after oxygenation indicated little or no change in cytochrome activity, but lowered catalase and endogenous dehydrogenase activities. During normal development, N moves from endosperm to embryo and the increase in embryo N follows the course of growth. In plants grown from oxygenated grains, N increase in the embryo occurs more slowly for a time and then stops, this behavior being correlated with the same type of growth pattern. Oxygenation at first slows down catalase activity and later causes its destruction. Development of catalase and dehydrogenase activities in intact embryos appears correlated with the movement of N from the endosperm to the embryo in both normal and oxygenated grains. Failure of N to move from endosperm to embryo in oxygenated plants is apparently not due to the mechanical removal of CO₂ by pure O₂, since N gas produces no comparable growth inhibition. On data presented, it is suggested that O₂ may interfere with proteolytic breakdown in the endosperm and, consequently, prevent N transport, development of enzyme activity, and finally growth.

Effects of mercury vapor upon seed germination, N. E. GRAY and H. J. FULLER. (Univ. Ill.). (*Amer. Jour. Bot.*, 29 (1942), No. 6, pp. 456-459, figs. 3).—Pea, corn, bean, radish, sunflower, and cucumber seed stored for 6 mo. in nearly airtight containers with Hg vapor suffered no ill effects, showing a slightly delayed germination but no decrease in germination percentage or early seedling growth. Pea, corn, and bean seedlings grown in the presence of Hg vapor in the surrounding air and in the substratum grew more poorly than those with Hg in the air only, and under both these conditions more slowly than in the total absence of Hg. In addition to their stunted growth, they also exhibited developmental failure, yellowing, and falling of the leaves.

Dormancy in seeds of *Convallaria majalis* L. and *Smilacina racemosa* (L.) Desf., L. V. BARTON and E. M. SCHROEDER (*Contrib. Boyce Thompson Inst.*, 12 (1942), No. 4, pp. 277-300, figs. 8).—Seed of these two plants were found to show a new type of epicotyl dormancy. Low temperature pretreatment was required for forcing shoot growth after the root had started to grow, but was effective only if given after the shoot had broken through the cotyledonary sheath. Embryo development to the proper stage for low temperature exposure was more rapid at greenhouse than at lower temperatures. The low temperature pretreatment increased root production from seed of *Convallaria* and was essential for root formation in *Smilacina* in soil plantings in the greenhouse. The best treatments for producing green leaves above soil in these plants are detailed. In commercial practice, seed should be cleaned and planted soon after harvest in the fall, and seedlings will appear above ground the second spring after planting. Some green leaves of *Convallaria* may be produced after one winter provided the planting is early enough to afford several weeks of warm weather, during which a small percentage of roots may grow. Under controlled temperatures, good seedling stands may be had within 9 mo. after harvest for *Convallaria* and 14 mo. for *Smilacina*.

Germination studies of seeds of *Symphoricarpos orbiculatus*, F. FLEMION and E. PARKER (*Contrib. Boyce Thompson Inst.*, 12 (1942), No. 4, pp. 301-307, fig. 1).—To induce germination of the seed it was found necessary to disintegrate the seed coat as well as to afterripen the embryo—accomplished by 3-4 mo. in moist peat moss at 25° C. followed by about 3 mo. at 10°. For producing seedlings on a large scale it is recommended that the seed be planted in flats of soil in the spring and held outdoors in a coldframe under a board cover during the subsequent winter, germination taking place the following spring. By combining the H₂SO₄ treatment described with a short period at high temperatures, seed-

lings can be obtained the first spring providing the seed are afterripened in a cellar maintained at about 10°.

A method for the culture of seedlings and small plants in sunlight under controlled temperature conditions, J. A. PINCKARD and L. S. BOZOVASKY. (Va. and Miss. Expt. Stas.). (*Phytopathology*, 32 (1942), No. 6, pp. 467-476, figs. 6).—The authors describe refrigerated plant-culture chambers for use in full sunlight at 65°-105° F. and in darkness down to 25°, ordinary commercial refrigeration equipment, apparatus, and materials being employed. The accuracy of control obtainable with the commercial equipment used was within 2°-3° of that desired. The principle of design adopted is described as the movement of low-velocity air at a stated temperature across surfaces exposed to light radiation.

The physiology and nutrition of plants under artificial light supplementing daylight (*Indiana Sta. Rpt.* 1941, pp. 83-85, fig. 1).—A brief summary is presented of four types of investigation, by R. B. Withrow, J. P. Biebel, and T. M. Eastwood, on the physiology and nutrition of plants under artificial light supplementing daylight and on the major results obtained.

Carbon dioxide evolution during the induction period of photosynthesis, J. FRANCK (*Amer. Jour. Bot.*, 29 (1942), No. 4, pp. 314-317).—Emerson and Lewis (*E. S. R.*, 87, p. 42) observed that with algae under special conditions a CO₂ evolution occurs at the beginning of an illumination period and were inclined to suppose that this process has no direct connection with photosynthesis. This paper purposes to show that what they observed is a special case of the normal induction period, and its interpretation is closely related to that given by Franck, C. S. French, and T. T. Puck² for other induction phenomena. From this standpoint CO₂ evolution is explained by back reactions, and thus lends support to the principle advanced by Franck and K. F. Herzfeld³ that such reactions influence the kinetics of photosynthesis whenever catalytic limitations occur.

Photosynthesis and absorption in blue radiation, G. R. BURNS. (Vt. Expt. Sta. et al.). (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 381-387, figs. 4).—The relative photosynthetic efficiencies, based on incident quanta, of white pine, Norway spruce, and Marquis wheat were determined in monochromatic radiation at several wavelengths, and some rough measurements of the absorption and the primary absorption were made at the same wavelengths. The relative efficiency of both pine and spruce at 5,461 a. u. and 5,780 a. u. was the same as in previous work (*E. S. R.*, 79, p. 458), and the efficiency at 4,358 a. u. was about the same as 5,461 a. u. The efficiency of wheat was highest in the blue, lower in the yellow, and the same or still lower in the green. The actual values depended on the pigment concentration or leaf number in a given volume. At 3,650 a. u. wheat showed large amounts of photosynthesis and pine none. The efficiency of wheat in the blue, green, and yellow radiation was roughly the same as its absorption and the same as its primary absorption. The efficiency of pine in the green and yellow radiation was much closer to the primary absorption than to the actual absorption, and in the blue radiation the efficiency was much lower than absorption. Pine apparently has absorption of radiation by inactive pigments in the blue and probably in the green and yellow.

A symposium on the structure of protoplasm: A monograph of the American Society of Plant Physiologists, edited by W. SIEFKE (*Ames: Iowa State Col. Press*, 1942, pp. VII+283, figs. [81]).—After the foreword, by W. E. Loomis, and the introduction, by the editor, the following papers are included: *Microscopic Structure of the Cell Wall*, by C. W. Hock (pp. 11-21); *Proteins and Protoplasmic Structure*, by L. S. Moyer (pp. 23-40) (Univ. Minn.); *Molec-*

² *Jour. Phys. Chem.*, 45 (1941), No. 8, pp. 1268-1300, figs. 25.

³ *Jour. Phys. Chem.*, 45 (1941), No. 6, pp. 978-1025, fig. 1.

ular Structure in Protoplasm, by C. L. Sponsler and J. D. Bath (pp. 41-79) (Univ. Calif.); Some Mechanical Properties of Solis and Gels and Their Relation to Protoplasmic Structure, by H. Freundlich (pp. 82-98) (Univ. Minn.); Structural Differentiation of Cytoplasm, by G. W. Scarth (pp. 99-107); Structural Differentiation of the Nucleus, by C. L. Huskins (pp. 109-126); Protoplasmic Streaming in Relation to Gel Structure in the Cytoplasm, by D. A. Marsland (pp. 127-161); The Relation of the Viscosity Changes of Protoplasm to Ameboid Locomotion and Cell Division, by W. H. Lewis (pp. 163-197); Physical Aspects of Protoplasmic Streaming, by N. Kamiya (pp. 199-244); Some Physical Properties of Protoplasm and Their Bearing on Structure, by W. Seifriz (pp. 245-284); and Protein and Protoplasmic Structure, by K. H. Meyer (pp. 287-270). Bibliographies follow each paper. The symposium ends with a letter from W. T. Astbury (with a comment by the editor) and a subject and author index.

Heterocaryosis and variability, H. N. HANSEN. (Univ. Calif.). (*Phytopathology*, 32 (1942), No. 7, pp. 639-640).—With the intent to clarify certain concepts of fungus variability, it is pointed out that heterocaryosis describes the condition of a cell or thallus containing genetically different nuclei. This phenomenon is initiated either by mutation in a plurinucleate cell or thallus or by anastomoses between cells having genetically unlike nuclei. Heterocaryosis is said to be the result, not the cause, of variation (mutation).

The cytonuclear ratio, V. V. TROMBETTA (*Bot. Rev.*, 8 (1942), No. 5, pp. 317-336).—This review (54 references) deals chiefly with the question of regularity of cell-nuclear size relationship in the growth and maturity of plants. Physiological inferences are "mentioned but not treated exhaustively."

Shrinkage and cell wall structure of cotton fibers, E. E. BERKLEY. (U. S. D. A.). (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 416-423, figs. 6).—Longitudinal shrinkage of cotton fibers dried from the "green" to the air-dry and oven-dry conditions was measured on seven varieties representing *Gossypium hirsutum* and *G. barbadense*, collected at frequent intervals beginning 10 days after the flowers opened. At 10 days the air-dry shrinkage was about 35-40 percent of the green moist length of fiber, between this and initiation of secondary thickening the shrinkage gradually decreased, then more rapidly for 2-5 days further, and after this it changed very little. There was an increase of about 4 percent in shrinkage when the waxes were removed. Details of various treatments given to the bundles of fibers are noted, but in no instance, after once dried to the air-dry or oven-dry state, did they swell to their original green length. The results presented are believed to confirm the microscopic and X-ray studies which indicate that the crystalline cellulose of the primary wall lies transversely to the long axis of the fiber or in a low spiral around it, and to indicate that only a small proportion of the primary wall is crystalline cellulose. There are 34 references.

An analysis of the comparative rates of cell division in various parts of the developing cucurbit ovary, E. W. SINNOTT (*Amer. Jour. Bot.*, 29 (1942), No. 4, pp. 317-323, fig. 1).—In 11 cucurbit lines of 3 genera, the increase in cell number between an ovary diameter of 2 mm. and one of 10 mm. was determined for the placental region and inner and outer wall and for the epidermis. Cell division was still taking place in all these regions. Between these two ovary sizes epidermal cell volume remained essentially constant, but in the other regions cell volume increased and at a higher rate in the inner than in the outer ones. Regional volume also increased faster in the inner than in the outer part, and there was a close correlation between rate of increase in cell volume and in regional volume. Cell number thus increases at essentially the

same rate in all four regions, so that rate of cell division is independent of cell size or position. The increase in cell number in all regions tended to be the same as the increase in ovary surface, and the physiological implications are discussed. The greater increase in volume of inner cells as compared to epidermis is a necessary result of the fact that the ovary volume increases faster than its surface but that the rate of cell division is constant. Possible reasons for the gradient in cell size from surface to center are suggested. The relation of the results of this study to various problems of growth and differentiation are discussed.

A method of growing plants in water vapor to facilitate examination of roots, W. CARTER. (Univ. Hawaii). (*Phytopathology*, 32 (1942), No. 7, pp. 623-625, figs. 3).—The plants are set in the perforated top of a simply constructed box in which is fixed an atomizing device, or in an air-conditioning apparatus. These devices permit a very fine jet of water or nutrient solution to impinge on a metal plate, which results in a steady drift of finely divided vapor. Domestic water pressure proved adequate.

The occurrence and types of vessels in the various organs of the plant in the Monocotyledoneae, V. I. CHEADLE. (R. I. State Col.). (*Amer. Jour. Bot.*, 29 (1942), No. 6, pp. 441-450, figs. 10).—"The present paper is a report on the occurrence and types of true vessels in the various organs from a wide representation of the Monocots." There are 30 references.

The development of vascular connections in the leaf-sheath of sugarcane, C. F. MORELAND and L. H. FLINT. (La. State Univ.). (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 361-362, figs. 6).—Radial and tangential cross-veinlets connecting vertical vascular bundles were observed within the leaf sheaths of sugarcane, being distributed at approximately regular intervals in the vertical plane and occasionally branched. These cross-veinlets originated within a single or branched horizontal line of parenchyma cells and for the most part remained restricted within the old boundaries of these cells. Temporary meristem was continuous with similar meristem within the vertical bundles, and differentiation extended to the elaboration of xylem and phloem. The development of a secondary meristem and the extension of such cambium from one vertical bundle to another indicated activities within monocotyledons similar to some of those more commonly associated with dicotyledons.

A comparative analysis of the vegetative characteristics of some variants of *Saccharum spontaneum*, E. ARTSCHWAGER (*U. S. Dept. Agr., Tech. Bul.* 811 (1942), pp. 55, figs. 26).—During recent years the increasing use of wild forms of *Saccharum* in sugarcane breeding has elicited an extensive interest in *S. spontaneum*, resulting in the assemblage at certain breeding stations of numerous clones from various parts of the indigenous range. The number has now become so large that a comparative analysis of the characteristics of the more divergent clones has become an acute need, and the present study was undertaken to obtain a better conception of the morphological relationships of certain elements of this complex group. In devising a system of identification for the various clones imported from Asia and the East Indies and grown at the United States Sugar Plant Field Station at Canal Point, Fla., different gross and minute morphological characters as well as certain microscopic features of the epidermis were employed. The presence of certain hair groups on leaf sheath, sheath base, and blade joint proved very useful in the major subdivisions, whereas qualitative differences had to be relied on for separating individual clones. The key given is intended to cover only the 23 clones here described. There are 11 references.

A quantitative morphological analysis of large and small leaves of alfalfa, with special reference to internal surface, F. M. TURBELL. (Calif. Citrus

Expt. Sta.). (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 400-415, figs. 23).—This study on the morphology of alfalfa leaves, details of which are given, was an outgrowth of interest in the responses of the leaves to SO_2 gas. From the evidence obtained it is concluded that large internal-external surface ratios, large volume of intercellular space, large stomatal pores, and large vein islet areas are positively correlated with large leaf size and the reported greater SO_2 injury in the larger leaves.

Development and relative growth in ovaries of *Iris fulva* and *I. hexagona* var. *giganticaerulea*, H. P. RILEY (*Amer. Jour. Bot.*, 29 (1942), No. 4, pp. 323-331, figs. 21).—Various radil of cross sections of developing capsules of these two irises were compared, and from the results as presented and discussed it is concluded that differences in the relative growth rates of the radil are due chiefly to differences in the relative growth rates of the ovary walls at those radil.

GENETICS

Genetics of pseudo-self-compatibility and its relation to cross-incompatibility in *Trifolium repens*, S. S. ARWOOD. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 12, pp. 699-709).—The original female parent of the white clover plants used set many selfed seeds when entire heads were manipulated but failed to set seed when 10 flowers per head were self-pollinated by hand in the greenhouse. The male parent was self-incompatible. The pseudo-self-compatibility of the female, transmitted to F_1 , F_2 , and backcross-generation plants, appeared to be conditioned by several genes additive in effect and heterozygous in the parents. Four intrasterile, interfertile groups of plants were found among the F_1 plants. Compatible F_1 intercrosses averaged 40.8 seeds per 10 flowers, the incompatibles 0.18. These cross-incompatibilities are explained by the diploid personate theory of oppositional allelomorphs if it is assumed that the parents differed in all 4 factors carried. In a further test by backcrossing 38 selected F_1 plants to the 2 parental and 4 F_1 groups, only expected groups were obtained. A certain genotype was assigned to each group, and the oppositional-factor hypothesis was confirmed for these pseudo-self-compatible plants. Of 41 plants from incompatible crosses or selfs, 12 were homozygous, 18 heterozygous, and 11 contaminants. Among the 12 were the 4 possible homozygous genotypes. One S gene from the pseudo-self-compatible parent was identical with the S , previously isolated from a self-incompatible plant. When the original female parent was backcrossed with F_1 , F_2 , and homozygous plants certain combinations failed where they were expected to be compatible, and the reverse held with others. These results were explicable by assuming that this original parent changed from S, S , to s, s , after the original cross as a result of either mutation or contamination in the field. Since plants of both relatively high and low pseudo-self-compatibility were in each of the 6 groups, little relationship evidently exists between the S factors and those conditioning ability to set some selfed seed after manipulation.

Inheritance of cross- and self-sterility and self-fertility in *Beta vulgaris*, F. V. OWEN. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 12, pp. 679-698, figs. 6).—Degree of self-sterility in beets was found to be determined by both environmental and heritable influences. Under greenhouse conditions, end-season self-fertility was pronounced with certain self-sterile plants. Intermediate types with a partly self-fertile condition, which was clearly heritable, were observed. Cross-sterility, common in the curly top-resistant line 12c, was often nonreciprocal in behavior, and an explanation based on a duplicate series of oppositional factors explained most of the results. A highly self-fertile condition was produced by a single Mendelian factor designated S^f . Self-sterile

plants were designated $S^a S^b$. The heterozygous S'/S^a plants bred true for self-fertility, presumably with the production of only S'/S' and S'/S^a offspring. In one instance reported, self-fertility arose suddenly in a self-sterile line, presumably by mutation.

Genetic stability of tomato diploids and tetraploids derived from haploid. E. W. LINDSTROM. (Iowa Expt. Sta.). (*Iowa Acad. Sci. Proc.*, 47 (1940), p. 75).—An absolutely homozygous tomato was obtained by doubling the chromosomes of a haploid form asexually. Ten generations of severe selection in an attempt to alter this pure line resulted in very minor changes. The original haploid now carried for 12 yr. asexually proved remarkably constant. Seven generations of selection for fertility in the homozygous tetraploid, derived asexually from the above diploid, have also had no effect in a population of over 400 plants. This pure autotetraploid is highly sterile, being less than 1 percent as fertile as its parental diploid.

The F_1 combining ability of certain tomato varieties. R. E. LARSON. (Minn. Expt. Sta.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 313–314).—First-generation hybrids between relatively new varieties and unnamed strains of tomatoes were grown in a randomized block test to determine their capacity to develop desirable characters such as early maturity, yield, size of fruit, etc. Earliness and size and shape of fruit were inherited intermediately. It was evident that the factors for increased yield are dominant in most F_1 hybrids, but the complementary effect of genes for yield in several crosses produced an F_1 that is higher in yield than either parent. None of the parents of the highest yielding crosses was high in productivity, suggesting that the performance of the parents cannot be used as a prediction for yield and that the testing of various combinations is the better approach.

Infertility in hybrid walnuts. J. W. MCKAY. (U. S. D. A.). (*North. Nut Growers Assoc. Proc.*, 32 (1941), pp. 84–86).—Studies of seedlings of two Maryland walnuts, Galley and O'Conner, presumptive hybrids between *Juglans regia* and *J. nigra* and characterized by extremely light bearing, showed wide variation in foliage characters and growth rates. Some of the seedlings resembled *J. regia*, and others were more like *J. nigra*. A few were intermediate. Cytological studies revealed a very irregular pairing of the chromosomes in the pollen and egg cells of the hybrid trees, indicating hybridity between rather widely separated species. Apparently the Galley and O'Conner walnuts are infertile chiefly because of the formation of aberrant pollen and egg cells in the staminate and pistillate blooms.

The inheritance of induced mutations in Neurospora tetrasperma. W. S. MALLOCH (*Mycologia*, 34 (1942), No. 3, pp. 325–347).—Eight character combinations derived from one X-rayed ascospore of this fungus were analyzed, and a genetic study of these characters indicated that the different types are governed by three pairs of factors, *Aa*, *Ww*, and *Pp*. *Aa* governs sex expression, *A* being associated with pale and *a* with salmon-orange conidiospore color. *W* and *w* are factors affecting the form of hyphal growth, *W* being a dominant for normal, and *w* a recessive for dwarf type of growth. *W* is strongly linked to *a*, and *w* to *A*. *Pp* governs perithecial development, *P* being associated with normal perithecial and ascospore production, and *p* with their reduced development. Different genetic combinations were produced by various interactions among these factors. The X-ray-induced alterations here studied behaved like gene mutations. Phenomena influencing the segregation of genetic factors in this fungus are presented. It is believed that *N. tetrasperma* should prove a favorable organism for investigating the nature of chemical substances produced by different genes, since both unisexual and bisexual types are available. As evi-

denced by the increased vigor of certain cultures, X-radiation provides a method for the creation of valuable new strains of fungi. There are 28 references.

Inheritance of pathogenicity in *Melampsora lini*, H. H. FLOR. (U. S. D. A. and N. Dak. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 8, pp. 653-669, figs. 2).—Pathogenicity inheritance in this rust was studied by selfing and hybridizing 6 physiologic races—3 heterozygous and 3 homozygous for pathogenicity. The segregation of selfed cultures of heterozygous races indicated each parent race to be heterozygous for a single pair of factors conditioning pathogenicity to 1 variety. The avirulence of race 6 on Akmolinsk and of race 20 on Buda were inherited as dominants. The moderate virulence of race 9 on Williston Golden was dominant to avirulence. Races differing in virulence on each of the 11 differential flax varieties were hybridized. In the F_1 , avirulence was invariably dominant, although on Buda it was incomplete. Consequently, the F_1 hybrid resembled the weaker of the 2 parents in pathogenicity or combined the less virulent characteristics of each. In a cross between races 6 and 24, 96 F_2 cultures segregated for infection types on Buda, Akmolinsk, and Bombay. The segregation for pathogenicity of these cultures was explained by assuming that infection type on Buda, which has 2 pairs of factors for resistance to race 6, was conditioned by 2 pairs of quantitative factors, and that infection type on Akmolinsk and on Bombay, each possessing a single pair of factors for rust reaction, was conditioned by single independent pairs of factors with avirulence dominant. The pair of factors conditioning virulence on Akmolinsk was closely linked with one of the pairs of factors for avirulence on Buda. Pathogenic characters in *M. lini* appear to be mendelian, and the pathogenic range of each physiologic race seems to be conditioned by pairs of factors that are specific for each pair of resistant or immune factors of the host variety. There are 17 references.

[Papers on animal genetics and physiology of reproduction] (*Anat. Rec.*, 82 (1942), No. 3, pp. 394-395, 397-398, 401, 402-403, 412-413, 414, 415, 422-423, 424, 429, 430, 432, 437, 441, 444-445, 447, 453-454, 458-459, 460-461, 462, 463, 465, 466-468, 471-472, 473-474, 475, 479, 482-484, 493).—Abstracts of the following papers on various phases of animal genetics and physiology of reproduction presented at the annual meeting of the American Association of Anatomists are included: Qualitative Differences Between the Morphogenetic Actions of Testoid Compounds, by S. Albert and H. Selye (p. 394); Relationships of Egg, Ovary, and Oviduct in the Albino Rat, by R. H. Alden (pp. 394-395); Further Studies of the Ovaries and Genital Tract at and Shortly after Ovulation, by E. Allen (p. 395); Maintenance of Deciduomata in the Mouse by Administration of Progesterone, by W. B. Atkinson (pp. 397-398); The Attainment of Sexual Maturity in the Female Rat, by R. J. Blandau, W. L. Money, J. R. Ring, and C. Fales (p. 401); Variations in the Rabbit Ovulation Response to Plant Juice Extracts, by J. T. Bradbury, J. W. Mitchell, and R. Borasky (p. 402), and Sex Maturity Factor in Plant Juices, by E. T. Gomez (p. 415) (both U. S. D. A.); The Oxygen Consumption of Skin During the Hair Cycle in the Normal Rat and After Adrenalectomy in Underfed Rats, by E. O. Butcher (p. 403); An Analysis of the Source of Melanophores in the Regenerating Feathers of Barred Plymouth Rocks, by J. G. Foulks (pp. 412-413); Mammary Growth in Hypophysectomized Male Mice, by W. Williams (p. 479); The Prevention of Castration Changes in the Pituitaries of Gonadectomized Rats as a Common Action of All Steroid Hormones, by E. Clarke, S. Albert, and H. Selye (pp. 482-483); Demonstration of the Sex-Inverting Power of the Sex Hormones, by V. Danchakoff (pp. 483-484); and The Effect of Sex Hormones on Sexual Behavior in Domestic Fowl, by L. V. Domm and D. E. Davis (p. 493).

[Animal reproduction and breeding investigations by the Indiana Station] (*Indiana Sta. Rpt. 1941*, pp. 45, 58, 90-92).—Results are briefly reported by F. N. Andrews, N. E. Weitkamp, J. F. Bullard, R. E. Erb, M. R. Zelle, C. M. Vestal, W. M. McVey, J. H. Hilton, J. W. Wilbur, J. H. Martin, C. S. Shaffner, C. W. Carrick, W. A. Hiestand, N. C. Wheeler, and E. E. Schnetzler of projects on the reproductive organs and semen production of bulls; the effect of thyroxine on milk secretion in beef cattle; breeding Landrace-Duroc and Chester White

swine and crosses between them; factors influencing fertility in bulls; preservation of fowl sperm by cooling and freezing; the influence of temperature and season on production of spermatozoa by fowls; production by breeding of market-type Plymouth Rocks; and breeding Leghorns for viability.

Heritability of conformation in Poland China swine as evaluated by scoring, H. H. STONAKER and J. L. LUSH. (Iowa Expt. Sta. coop. U. S. D. A.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 99-105).—The scores of 1,460 pigs based on six items—health and vigor, quality, length of body, details of conformation, animal as a whole, and market grade—recorded in spring and fall litters over a 3-yr. period at the U. S. Regional Swine Breeding Laboratory showed that the last three seasons averaged 1.5 points higher than the first three. A perfect score for each item was 9. Treatment of the variance showed that 7 percent was between seasons, 11 percent between progeny averages of the contemporary sires, 11 percent between litter averages, and 71 percent between litter mates. With a calculated heritability of 20 percent and with the parents scoring 3.55 points higher than the average of the population in the season in which they were raised, it was estimated that the average score would increase 0.71 point per generation. The number of pigs raised per litter by a sow to 225 lb. tended to increase by 0.05 for each point increase in the score of the sow as a gilt.

Genetic resistance to brucellosis in swine, H. S. CAMERON, E. H. HUGHES, and P. W. GREGORY. (Univ. Calif.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 106-110).—From a study of the genetics of resistance of swine to a uniform oral dose of *Brucella suis* of constant virulence (E. S. R., 84, p. 819), a working hypothesis was proposed that resistance is recessive and monofactorial with a penetrance of about 77 percent. Undetermined reactions because of agglutination to low dilutions but not in higher dilutions at 8 weeks of age made some of the conclusions tentative. Among 23 litters from resistant \times resistant parents, there were 98 resistant, 1 susceptible, and 29 partially reacting progeny.

A pale variation in a ground squirrel: Notes on a pale individual of the thirteen-striped ground squirrel *Citellus tridecemlineatus tridecemlineatus*, (Mitchill), E. FICHTER and L. D. DAVIS. (Univ. Nebr.). (*Jour. Hered.*, 33 (1942), No. 4, pp. 153-155, fig. 1).—In a litter of six 13-striped ground squirrels found in nature there occurred one lighter-than-normal individual. Although there were no breeding tests, the condition was considered due to a recessive gene.

A new type of autosomal nakedness in the domestic fowl, P. D. STURKIE. (Ala. Expt. Sta.). (*Jour. Hered.*, 33 (1942), No. 5, pp. 202-208, figs. 2).—A dominant type of nakedness in the domestic fowl which was somewhat variable in character but resulted from a complete absence of pteryllae in the areas concerned is described. The alar wing tract was always normal, and the leg or crural tract was only partially devoid of feathers. Matings of the progeny of heterozygous naked δ s with normal ? s produced 958 naked to 961 normals. Matings of naked ? s with normal δ s also proved naked to be autosomal and dominant. F₂ matings further showed the usual 3:1 ratios. In accordance with Fisher's theory of modifiers of dominance in the fowl (E. S. R., 64, p. 330), the progeny of 5 naked sires were found to show significant differences in the character of nakedness in their progeny. Some of the modifiers seem to be sex-linked, but selection seemed without effect. Among eggs producing normal and naked chicks 90 percent and 87.6 percent, respectively, hatched. Mortality was much higher than normal in naked chicks, being 54.1 percent at 10 days of age for naked as contrasted with 2.1 percent for normals. Lethality was not related to the degree of feathering. The weights and feed consumption of naked birds were consistently lower than those of normals at comparable ages from 3 to 24 weeks. Egg production of naked and sexual maturity of ? s was normal.

The regression of the avian post-ovulatory follicle, D. E. DAVIS (*Anat. Rec.*, 82 (1942), No. 3, pp. 297-307, pls. 2).—The regression of the post-ovulatory follicle in bird ovaries, primarily from 17 Argentine Cowbirds, is described. During the regression process the granulosa became vacuolated and phagocytosed. The post-ovulatory follicle of birds is not identical with the corpus luteum of mammals because there is no proliferation or hypertrophy of the granulosa tissue since this structure regresses and undergoes phagocytosis after ovulation.

Auto-sexing in the domestic pigeon, W. F. HOLLANDER (*Jour. Hered.*, 33 (1942), No. 4, pp. 135-140, fig. 1).—Autosexing in the pigeon is possible with the sex-linked factors almond and faded. The hemizygous almond ♀ is white flecked, and the condition increases with age. The homozygous ♂ generally showed the flecks more extensively. Faded had a more general utility because in young squabs the ♂ showed a shorter down and nonpigmented beak. In adults the homozygous ♂ was white with a slight but general pigmentation. The hemizygous ♀s were of normal coloration but faded. The use of faded for sex identification is recommended.

Relationship between body size and metabolism, F. W. WEYMOUTH, J. FIELD, II, and M. KLEIBER. (Univ. Calif. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 367-370).—Recalculation of the relation of metabolism and body size (E. S. R., 86, p. 663) led to the conclusion that the mechanism of respiratory regulation must account for variations from tissue to tissue, species differences, similar relation of body and oxygen consumption, and relation of respiration to body size in separated and intact tissues. The metabolism of the several tissues parallels that of the animals as a whole.

Twinning in horses, L. H. BLAKESLEE and R. S. HUDSON. (Mich. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 155-158, fig. 1).—From 174 parturitions of Belgian and 229 of Percheron mares in the college herd only 2 mares produced surviving twins. The sex ratio was approximately equal.

Chemical studies of bull spermatozoa: The methionine content of whole spermatozoa and of the parts obtained by physical means, C. A. ZITTLE and R. A. O'DELL (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 239-243).—Most of the sulfur found in bull sperm was accounted for by the methionine and cystine present in the sperm heads, middle pieces, and tails, as ascertained by physical separation of the parts.

Effect of diluters and storage upon fecundity of bovine semen, G. K. L. UNDERBERG, H. P. DAVIS, and R. E. SPANGLER. (Nebr. Expt. Sta.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 149-154).—In a study of 931 cows artificially inseminated with bovine semen, undiluted and diluted with fresh and stored egg yolk buffer and autoclaved milk, the treatment accorded these samples did not cause a significant lowering of the conception percentages as contrasted with controls. Despite the maintenance of sperm motility, stored groups showed a significant departure in conceptions from the fresh materials. Evidently the treatments had little beneficial effect on fecundity, but other factors were in operation during storage which caused a loss of the fertilizing capacity regardless of the retention of motility.

The effect of sex on the development of the pig.—II, Urinary excretion of androgens by boars of different lines of breeding, W. W. GREEN, L. M. WINTERS, J. R. RASH, JR., and D. L. DALEY. (Minn. Expt. Sta. coop. U. S. D. A.). (*Jour. Anim. Sci.*, 1 (1942), No. 2, pp. 111-115).—Continuing this series (E. S. R., 87, p. 210), determination of the urinary androgen excretion by boars showed individual variations, but boars of one inbred line excreted much more androgen than boars in another line. In the conduct of the study 105 48-hr. urine samples were assayed by the capon comb test and by the colorimetric method. A correlation coefficient of 0.8 was found between these results.

A comparison of the reactions of male and female rat prostate transplants. D. PRICE (*Anat. Rec.*, 82 (1942), No. 1, pp. 93-113, pls. 2).—Prostatic tissue from ♂ and ♀ rats showed similar development in ♂ and ♀ hosts, and therefore it was assumed that both react to androgens of testicular and presumably adrenalin origin. Subcutaneous transplants were made in 164 hosts from a strain in which approximately 27 percent of the ♀s have ♀ prostates. Tissues from either sex of animal responded equally well to testicular androgens.

Effects of testosterone propionate in spayed female rats. G. L. LAQUEUR (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 425-426).—Injection of testosterone propionate on alternate days into ♀ rats spayed in oestrous and dioestrous prevented castration atrophy of the uterus. Castration apparently inhibited the increase in body weight found in controls. The study was conducted with six groups of six rats each castrated at different stages of the oestrous cycle.

Mitotic activity in the anterior hypophysis of female rats. T. E. HUNT (*Anat. Rec.*, 82 (1942), No. 3, pp. 263-276).—Mitotic activity in the hypophysis of the ♀ rat was shown to decline from about 90 per square millimeter at 1 day of age to 1-6 mitoses in a comparable section at more advanced ages. After sexual maturity the number of mitoses depended on the stage of the oestrous cycle, but maximum activity was not found in animals over 111 days of age. In pro-oestrous and dioestrous there were relatively few mitotic figures, but during the latter half of oestrous as many as 72 mitoses per square millimeter were found. These conclusions were derived from histological study of hypophyses from 67 ♀ rats.

The origin of ova in the adult opossum. N. B. EVERETT (*Anat. Rec.*, 82 (1942), No. 1, pp. 77-91, pls. 3).—Histological study of the ovaries of 32 sexually mature opossums showed that new ova were formed during adult life in the germinal epithelium. Few new ova were produced during pregnancy and oestrous, most being formed in the nonpregnant animal during the close of the anoestrous period. The cytology and development of ova are described and illustrated.

Maturation, fertilization, and early cleavage in the hen's egg. M. W. OLSEN. (U. S. D. A. and Md. Expt. Sta.). (*Jour. Morphol.*, 70 (1942), No. 3, pp. 513-533, pls. 2).—Study was made by serial sections of developmental changes which occurred in more than 300 blastodiscs in various stages during development in the ovaries or oviducts of White Leghorn and Rhode Island Red hens. Various cytological changes in the developing and fertilizing ova were described. Within 4 hr. after an egg enters the uterus cleavage of the blastodisc has progressed from the sixteenth to approximately the two hundred and fifty-sixth cell stage.

Relation of time of insemination to percent fertility. O. K. MOORE and T. C. BYERLY. [Md. Expt. Sta.]. (*Poultry Sci.*, 21 (1942), No. 3, pp. 253-255, fig. 1).—Variations in the time of insemination were found to determine the percentage fertility of 1,046 eggs incubated in these studies. When birds had a hard-shell egg in the uterus there was a tendency toward low fertility, the average mean percentage being 39. When an egg had just been laid and the birds were artificially inseminated 59 percent proved fertile, and it was considered that the maximum fertility followed 3-4 days after insemination.

The problem of distinguishing the sex of day-old chicks. W. C. THOMPSON and L. M. BLACK (*New Jersey Stat. Cir.* 433 (1942), pp. 11, figs. 7).—Descriptions are given of the methods of sexing day-old chicks, Wax models of differences found, with morphology of the everted vents with accuracy attained in the different types, are presented.

FIELD CROPS

[Field crops research in Idaho, 1941]. (Partly coop. U. S. D. A.). (*Idaho Sta. Bul.* 244 (1942), pp. 18-19, 20, 21-23, 43-47, 49-51, 58-62, fig. 1).—Agronomic experimentation at the station and substations (E. S. R., 85, p. 750), reported on briefly by D. K. Schultz, K. H. W. Klages, D. Peterson, G. O. Baker, E. VanSlyke, C. F. Dietz, L. Verner, C. Arnold, J. L. Toevs, J. E. Kraus, E. W. Whitman, G. Rothwell, J. M. Raeder, R. E. Knight, and W. A. Moss, included breeding work with wheat, oats, barley, alfalfa, potatoes, and corn; variety tests with winter and spring wheat, barley, oats, corn (and hybrids), alfalfa, potatoes (and seed stocks), grain sorghum, sorgo, forage grasses, and pasture mixtures; experiments on the production of seeds of grasses and clovers; cultural experiments with potatoes and different grasses; seedings of grasses and legumes on burned-over land; fertilizer trials with potatoes and grasses; influence of soil management and crop rotation practices on yields of wheat; measuring potato tuber growth with a new device; hastening maturity of potato tubers by killing vines with chemical sprays; and grade, storage, and cooking quality studies with potatoes.

[Farm crops experiments in Indiana]. (Partly coop. U. S. D. A.). (*Indiana Sta. Rpt.* 1941, pp. 17-18, 31-42, 49, 50, 51, 53-54, 87, 102, 103, fig. 1).—Research with field crops and related studies (E. S. R., 86, p. 32) at the station and outlying farms, reported on briefly by D. M. Doty, G. D. Scarseth, C. L. Comar, H. E. Jones, H. A. Nash, S. R. Miles, M. S. Bergdoll, C. E. Skiver, R. R. Mulvey, G. P. Walker, W. W. Worzella, M. Drake, R. E. Lucas, U. S. Jones, H. L. Cook, A. J. Ohlrogge, B. A. Krantz, G. H. Cutler, A. H. Probst, G. O. Mott, A. M. Brunson, R. M. Caldwell, L. E. Compton, R. E. Lincoln, R. W. Samson, J. L. Roberts, F. R. Olson, G. M. Smith, A. J. Ullstrup, F. C. Gaylord, K. I. Fawcett, and A. T. Wiancko, comprised variety tests with corn and hybrids, popcorn, wheat, oats, sorgo, and potatoes for quality; breeding work with corn and hybrids, popcorn, wheat, oats, soybeans, potatoes, and red clover; inheritance of characters in wheat; investigations on the correlation between yielding ability in hybrid field corn and susceptibility to *Diplodia* stalk rot; inheritance of seedling resistance to leaf rust in Wabash wheat; fertilizer experiments with corn, wheat, soybeans, and alfalfa, and various crops in rotation; chemical composition and nutritive value of corn as related to soil type and fertilizer treatment; effects of soil, climate, and maturity on the composition of hybrid and open-pollinated varieties of dent corn; corn fertilization problems involving the use of ammonium sulfate; cyanamide as a source of N for corn and residual effects on oats; fertilizer placement with corn and soybeans; effects of top dressing of N carriers and manure and efficiency of P carriers on wheat; the fertility value of cornstalks; effect of different systems of manuring wheat and corn; residual effects on hay fields of fertilizer applied to wheat and crop residues; effect of tile drainage on hay yield and quality on Clermont silt loam; availability of P to soybeans; grain farming v. livestock farming; clover v. timothy as a rotation hay crop; interrelationships of legumes and grasses grown in associations; factors affecting winter hardiness, yielding ability, and milling and baking qualities of wheat; adaptation of Atlas sorgo as a silage crop in southern Indiana; value of sweetclover as an intercrop in a rotation of corn and oats; harvesting sweetclover for hay v. intercropping; planting tests with corn and soybeans; and pasture experiments, including agronomic study of various species and varieties of pasture plants and mixtures, fertilization of permanent pasture under southern Indiana conditions, a study of the adaptation of rotation pastures of different kinds and of permanent pasture to beef cattle production, and the effects of fertilization upon the composition and production of permanent bluegrass pasture.

[Farm crops research in Mississippi] (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), Nos. 5, pp. 1-2, 3-6, 7, 8, figs. 9; 6, pp. 1, 2, 7, 8).—Articles reporting agronomic research are given as follows:

No. 5.—Fertilizer and Cropping History: Influence on the Present Fertility Needs, by W. B. Andrews (pp. 1, 8); Harvesting Winter Legume Seeds To Meet Farm Needs (p. 1), Cultural Practices for Cotton Grown on Buckshot Soils (p. 2), and Fertilizer Tests for Cotton Growing on Delta Loam Soils (p. 7), all by R. Kuykendall; and Growing Peanuts To Meet War Needs, by R. Coleman and H. O. West (pp. 1, 3-6).

No. 6.—Cultivation Schedule for Cotton Crop, by R. Woodburn (pp. 1, 2); Timely Mowing for Control of Weeds, Improved Pastures, by H. W. Bennett (pp. 1, 8); and Thoro Cultivation for the Eradication of Johnson Grass, by O. A. Leonard (p. 7).

Grassland maintenance in Vermont.—I, A preliminary study, D. E. DUNKLEE and A. R. MIDGLEY (*Vermont Sta. Bul.* 484 (1942), pp. 14, pls. 4).—Grassland on five soil types received fertilizer treatments on the sod in late fall and early spring, but no seed was sown. Yields when cut as hay and pasture were recorded, 1937-40. Complete fertilizer (10-10-10) resulted in outstanding improvement in dry-matter yields, vegetative composition, and herbage quality. N used alone, as cyanamide, calnitro, or urea, was not effective in prolonging or stimulating the life of grass-hay stands. Early spring applications of complete fertilizer usually were superior to those made in the late fall. Cut as hay, herbage yields were practically twice as much as when harvested as pasture. Complete fertilizer increased growth in early spring as well as in the summer dry period, but did not change the peak. Other trials with 14 seeds mixtures on uniformly fertilized and grazed plats demonstrated that the vegetative composition was determined by the plant-food level and by grazing management rather than by the nature of the several mixtures.

High quality hay production, G. H. AHLGREN and C. B. BENDER (*New Jersey Stat. Ctr.* 440 (1942), pp. [4]).—Cultural and fertility practices before cutting and curing and handling and storage practices after cutting are outlined, with high-quality hay as the objective. The stages of maturity for cutting different hay crops are tabulated.

The relation of the dispersion ratio to the type and amount of pasture vegetation, G. M. BROWNING and H. G. FOGLE. (W. Va. Expt. Sta. coop. U. S. D. A.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 42-44, figs. 6).—The authors show the existence of highly significant negative correlations between the dispersion ratio and the percentage of desirable species ($r = -0.222$), dispersion ratio and the organic matter content ($r = -0.641$), dispersion ratio and the pH ($r = -0.240$), organic matter and bare space ($r = -0.424$), and desirable species and bare space ($r = -0.580$). A highly significant positive correlation ($r = 0.401$) was found between the dispersion ratio and the percentage bare space. In general, increase in the percentage of desirable species, the organic matter content, or the pH was accompanied by a decrease in the dispersion ratio, whereas increase in the percentage of bare space resulted in increase of the dispersion ratio. The use of lime and superphosphate in addition to proper management practices materially increases the carrying capacity and reduces losses of soil and water by improving the type and density of the vegetative cover.

The effect of lime and fertilizer on the composition and yield of pasture herbage in Alabama, J. W. MCCLENDON and E. L. MAYRON. (Ala. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 6 (1941), pp. 285-287).—The yield and mineral content of pasture plants were increased greatly by lime and fertilizer on the soil types studied, 1938-40, at three substations. Fertilizer applied once in 3 yr. was

superior to the same amount divided into three annual applications in all experiments. K became a limiting factor on the alkaline soils of the Black Belt where heavy rates of P were applied. Regardless of fertilization, the quality of plants from the Gulf Coast Substation did not exceed that of plants from unfertilized checks at the Black Belt Substation. A similar relation held in regard to plants from the Black Belt Substation and those from unfertilized checks at the Tennessee Valley Substation.

Some effects of black locusts and black walnuts on southeastern Ohio pastures, R. M. SMITH. (U. S. D. A.). (*Soil Sci.*, 53 (1942), No. 5, pp. 385-388, figs. 6).—The effect of trees upon pasture grasses represents the net result of the reduced light, the tree leaf fall, the tree root competition with the grass and with weeds, and the many indirect reactions of these factors through soil condition, soil moisture, soil temperature, and soil organisms. Whether this net effect is beneficial or detrimental depends upon the type of pasture, the type of soil, the climate, and the season, as well as upon the type of tree. For southeastern Ohio a tree should possess approximately the following characteristics: Its period of leaf activity should extend only from about June 15 to September 15; its canopy should admit approximately 50 percent of the bright open sunlight to the grass during its period of leaf activity; its leaves should be small, fragile, and very high in minerals and nitrogen; its root system should extend to a great depth and be highly developed but should feed mainly below the surface 4 in. of soil; it should be a nitrogen-fixer; it should be capable of establishment on poor upland sites; and it should possess high commercial value. The black walnut approaches the ideal in more ways than any other common species. Its greatest weakness is its inability to fix atmospheric nitrogen. The black locust approaches the ideal in more ways than most other common trees, foremost among its desirable characteristics being its ability to fix atmospheric nitrogen.

Some factors affecting the content, fluctuation, and distribution of white clover in permanent sod areas in Ohio, D. R. DODD. (Ohio Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 6 (1941), pp. 288-297, figs. 13).—Experiments contributed information on factors affecting the fluctuation and distribution of white clover in the permanent sod lands. White clover was very valuable in permanent sods since it improved the quality, the growth, and color of the sod and helped to control weeds. Where lime was not abundant in the surface soil, liming was essential to satisfactory development of white clover, and the need for P a close second. Considerable differences were noted among white clover strains in general characteristics, growth habits, and ability to endure unfavorable weather. Control of grass growth in pastures and lawns is necessary to the maintenance of a satisfactory white clover content. This clover content of permanent sod areas fluctuates in response to weather.

Other studies and experiments in the program of the San Joaquin Experimental Range, M. W. TALBOT, H. H. BISWELL, P. B. ROWE, and A. W. SAMPSON (*California Sta. Bul.* 663 (1942), pp. 136-142).—Brief descriptions are given of the purpose, nature, and scope of studies concerned with artificial reseeding, rainfall runoff and erosion, and the chemical composition of the important range plants.

The forage crop and its management, M. W. TALBOT and H. H. BISWELL (*California Sta. Bul.* 663 (1942), pp. 13-49, figs. 5).—The forage on the San Joaquin Experimental Range is described, with discussion of its characteristic growth and behavior and a report on experiments on grazing to give maximum yields with concurrent maintenance and possible improvement. Progress results show that new green growth was available from 2 to 3 weeks earlier on areas

where some old feed was left for protection than on areas closely used the previous season. Forage composition and density were not affected appreciably in 3 yr. by different rates of use for the grazing period of about 7 mo. each year. Surface soil litter decreased on the most closely used areas. This annual forage cover under certain conditions might change very readily if completely protected from grazing.

Alfalfa breeding, H. M. TYSDAL, T. A. KIESSELBACH, and H. L. WESTOVER. (Coop. U. S. D. A.). (*Nebraska Sta. Res. Bul.* 124 (1942), pp. 46, figs. 14).—Information on the improvement of alfalfa (E. S. R., 85, p. 614) is assembled and suggestions are made on future possibilities. The objectives of breeding, relation of characters, and the genetics and cytology of alfalfa are reviewed briefly. New data reported, obtained through the cooperative breeding program, provide information on the amount and manner of natural crossing, the effects of inbreeding and hybridization, and the possible commercial utilization of hybrid vigor in alfalfa. Improvement practices examined comprise (1) mass selection with its modifications of strain-building and maternal-line selection, (2) recombination of selected inbred lines as synthetic varieties, and (3) hybridization for use as F_1 hybrids, with the respective resultant improved products known as (1) improved selections or strains, (2) synthetic varieties, and (3) F_1 hybrids. Concluding that the principles of breeding alfalfa, with some modifications, are essentially the same as those established for corn, the authors outline a program to develop either a superior synthetic or a hybrid including the following steps: Careful choice of the original varieties; epidemic, breeding, and polycross nurseries; and production of hybrid alfalfa. Literature cited embraces 43 titles.

Bronco grass (*Bromus tectorum*) on Nevada ranges, C. E. FLEMING, M. A. SHIPLEY, and M. R. MILLER (*Nevada Sta. Bul.* 159 (1942), pp. 21, figs. 13).—Bronco grass, an annual introduced from Europe, first appeared in Nevada about 50 yr. ago as a weed of roadsides and alfalfa. At present it grows throughout the sheep and cattle ranges in varying degrees of density and has become a permanent source of feed in northern and central Nevada range areas, where it is especially desirable for spring lambing. The grass is a prolific seeder, is not very exacting in soil requirements, can compete successfully with perennial range grasses, and is uniform in forage production. Maximum volume of forage is produced by June 15 each year, and the amount per square foot of 10–10 density is influenced greatly by the amount and distribution of spring moisture. Bronco grass is palatable and nutritious to all classes of livestock in the green and succulent stage. If moisture is ample new growth is made after grazing. If soil moisture is available in late summer or early fall, new growth comes from seed produced the preceding spring, and the fall growth is as nutritious and palatable as early-spring growth. The grass was found to compare favorably in nutrient values with the perennial range grasses bluebunch wheatgrass, bluebunch fescue, and Sandberg bluegrass at comparable stages of growth and maturity, although not quite so palatable, and it can withstand untimely and heavy grazing better. The seeds of this grass cause eye and mouth injury to cattle and more so to sheep in summer or fall months. Bronco grass creates a serious fire menace when fully mature and dry, although under Nevada conditions it is not killed out by burnings. It is susceptible to heavy smut infestations which decrease its palatability at maturity.

Hybrids help growers meet production goals on corn in "food-for-freedom" drive, W. H. LEONARD and H. FAUBER (*Colo. Farm Bul.* [Colorado Sta.], 4 (1942), No. 2, pp. 25–27).—Continued trials of corn hybrids (E. S. R., 85, p. 476) showed Iowa 3080, Iowahealth AP, DeKalb 240, Funk G-7, Iowahealth A,

Wisconsin 696, and Pioneer 332, in order, as the high yielders of those tested for 2 yr. or longer, 1937-41, in comparison with Minnesota 13 at Fort Collins. At Rocky Ford, 1937-41, compared with Reid Yellow Dent the ranking was Pioneer 307, Funk G-212 and G-135, Pfister 160, Iowa 160, Iowa 160, and DeKalb 816. The adaptations of these and other hybrids are discussed briefly.

Cation balance in corn grown on high-lime soils in relation to potassium deficiency. G. STANFORD, J. B. KELLY, and W. H. PIERRE. (Iowa Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 6 (1941), pp. 335-341, figs. 5).—In field experiments on high-lime soils the K, Ca, and Mg contents of normal and K-deficient corn plants were compared at different growth stages. Unproductive soils contained less exchangeable K and more Ca and Mg carbonates (expressed as the CaCO_3 equivalent) than the normal soils. A close relation existed between corn yield and the amounts of exchangeable K in the soil. For plant samples at an early stage of growth in 1940 the amount of K absorbed per 100 gm. of dry plant material was correlated closely with the exchangeable K content of the soil. K fertilization reduced the content of Ca and Mg per unit weight of the plant. Greenhouse and field experiments gave evidence that K applied to the unproductive soils repressed the uptake of Ca and Mg by the plants. The Ca + Mg/K ratio in young corn plants sampled in 1940 was a function of the amount of exchangeable K in the soil. Consideration of all plant analyses revealed that Ca + Mg/K ratios of 3.5 or less occurred in apparently normal plants. Ratios of 5 or above were found in plants showing marked symptoms of K deficiency. Poor growth of corn on Iowa high-lime soils appeared due largely to failure of the plants to absorb adequate amounts of K from the soil. A consequence of the low rate of K absorption is an unfavorable balance between cations within the plant.

Kansas corn tests, 1941. A. L. CLAPP, R. W. JUGENHEIMER, H. D. HOLLEMBRAK, and J. H. LONNQUIST. (Coop. U. S. D. A.). (*Kansas Sta. Bul.* 299 (1942), pp. 47, figs. 2).—Further tests of corn hybrids and varieties under the Kansas corn-testing program (E. S. R., 85, p. 45) were made in 1941. Hybrids (listed alphabetically) yielding above the average of all 35 entries in fields in all 3 eastern districts in 1941 were Iowa 160 TX 1, Kansas 1585, 1624, 1638, and 2232, K. I. H. 38, Reid-Midland, and U. S. 13. During 1940 and 1941 the hybrids standing up as well as the average of the better open-pollinated corn, producing at least 15 percent more corn, and having a combined advantage in lodging resistance and grain yield of not less than 25 percent in all 3 eastern districts, were Funk G-94, Illinois 200, Kansas 1104 and 2232, Pioneer 307 and 332, Pfister 380, and U. S. 13 and 35. Some hybrids that made a high yield in cooperative strip tests in all 3 eastern districts in 1941 were Funk G-94, Illinois 200, K. I. H. 38, Kansas 1104, U. S. 13, and Kansas 1466, and for central Kansas were Kansas 1466, U. S. 13, Kansas 1412 and 11, U. S. 35, and Illinois 200.

Factors in the breeding of cotton for increased oil and nitrogen content. N. I. HANCOCK (*Tennessee Sta. Cir.* 79 (1942), pp. [7]).—Data from varietal studies with cotton in three localities in Tennessee are analyzed and discussed in relation to factors involved in improvement, by breeding, of the oil and N contents of cottonseed. Both the oil and N content of cottonseed have been shown to be definite plant characters stable within the variety but differing significantly among varieties. The inverse relationship of the oil to N character is attributed largely to their noncompatibility with the environment—a wet, cloudy season being favorable to oil but unfavorable to N. Seasons appear to exert more influence upon this inverse relationship than do locations. The possibility of obtaining a variety high both in oil and N content is mentioned.

Mung beans for Oklahoma, H. W. STATEN (*Oklahoma Sta. Cir. 104 (1942)*, pp. 7, fig. 1).—Varieties, adaptation, and cultural and harvest practices are outlined for growing mung beans (*Phaseolus aureus*) for forage, commercial sprouting and canning, and soil improvement. The golden variety, grown primarily for soil building, hay, silage, and pasture, will yield from 1 to 2 tons of air-dry hay per acre and average from 4 to 5 bu. of seed. Green varieties yield from 12 to 15 bu. of seed but only half as much hay as the golden. The bean sprouts are used particularly by the Chinese restaurants for making chop suey, chow mein, and other food.

Winter injury as related to fall and winter growth and crown-rust infection in oat varieties and their hybrids, H. R. ROSEN, L. M. WEETMAN, and C. K. McCLELLAND (*Arkansas Sta. Bul. 418 (1942)*, pp. 17, figs. 4).—Selections of oats hybrids and parental material, including hardiest varieties available, were subject to severe cold during the 1939-40 winter. The survival for all parents was very low, ranging from 28 percent for Tennex to 0 for a number of other varieties. Thirty-eight selections, much hardier than any of the parents, ranged in survival from 40 to 90 percent. Most selections did not surpass the parents, and some did not equal them. More than 5,000 selections of individual plants from hybrids surviving the winter of 1939-40 and having other desired characters, particularly crown rust resistance, were planted early in September 1940, and, with favorable conditions lasting for 2 mo., made good growth. A severe epidemic of crown rust developed, and all susceptible selections and susceptible parent varieties became infected, varying from a trace to over 50 percent. During rapid growth and before the plants could harden the temperature fell to 24° F. on November 11 and remained below freezing during most of the next 6 days, reaching a low of 9°. Many nonhardy selections and parents were completely killed, while harder parents showed from 85 to 70 percent leaf injury, some of which could be attributed to reduction in hardiness due to severe crown rust infection. The many hardy selections showing appreciably less injury than the hardiest parents included some that made considerably more growth for winter pasture than the hardy parents, and were homozygous for resistance to crown rust, some to both crown and stem rust, and to smuts. Oats possessing considerable hardiness evidently can be bred, and such hardiness can be coupled with excellent growth for winter pasture, with rust and smut resistance, and with good grain yields.

Progress report of potato research, J. E. KRAUS ET AL. (*Idaho Sta. Cir. 85 (1942)*, pp. 7).—Brief progress reports are made on studies at the Aberdeen Substation and the station showing that large seed piece and close planting produce best yields, cut seed exposed to hot, dry conditions decays quickly, lack of moisture may cause jelly-end rot, causes for cull grades of commercial potatoes vary, and high temperatures are not favorable for potato storage. Comments are also made on plant symptoms of bacterial ring rot, occurrence of *Fusarium* wilt, improvement and testing of seed stocks, tests of methods of hastening maturity or skin setting on late potatoes, and fertilizer experiments.

Influence of flowering and fruiting upon vegetative growth and tuber yield in the potato, W. L. BARTHOLDI (*Minnesota Sta. Tech. Bul. 150 (1942)*, pp. [1]+20, figs. 3).—That flowering and fruiting both caused significant reductions in vegetative growth and tuber yields was shown in studies with four potato varieties at two locations. Fruiting plants, and to a lesser extent flowering plants, tended to produce a smaller weight of vines than did nonflowering, nonfruiting plants. This was noted in the early developmental growth stages following a period of most active flowering and fruit set. Association between extent of flower and fruit production and vine growth was indicated, although marked de-

creases were observed with the lighter flowering, less fruitful individuals. Growth of underground parts (stolons plus roots) closely paralleled that of vines, and similarly, flowering and fruiting tended to reduce the ultimate size of these portions.

Measurements on total yield of tubers and number of tubers reaching marketable size (over 85 gm.) disclosed that yields were reduced significantly on both fruiting and flowering plants of all varieties as compared to nonflowering, non-fruiting plants. Fruit formation and tuber production were concurrent processes. Decrease in yield appeared to be related to the number of flowers and fruits formed. Yield reductions per gram of fruit set and per flower formed tended to be greater on the lesser flowering and less fruitful plants. Flowering and fruiting evidently reduced total number of tubers set and number and weight of tubers reaching marketable size.

Soil element tests help food-for-freedom program, pointing way to better potatoe, J. G. McLEAN and W. C. SPARKS (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 2, pp. 23-25).—The red color of the skin of Red McClure potatoe, grown in the San Luis Valley, and to a lesser extent of Triumph, grown at Fort Collins, was increased with sulfates of Fe, Cu, and Mn. Zinc sulfate resulted in tubers generally darker than the untreated controls, calcium carbonate and magnesium sulfate showed no effect on color, while sodium carbonate resulted in light red tubers and borax in light colored potatoe, often with a pinto appearance. Various effects on tuber shape were noted. Planting date also exerted some influence on skin color.

A study of problems relating to production of fall-crop Irish potatoe in Oklahoma, H. B. CORDNER (*Oklahoma Sta. Bul.* 258 (1942), pp. 59, figs. 15).—The several causes of crop failures in fall potato production were studied, 1937-40, and certain practices were found helpful in overcoming these failures. Successful production mainly depends upon the development of a good stand of plants, followed by the continuous development and maturation of the crop. See also an earlier report (E. S. R., 84, p. 40).

High soil temperatures, especially 90°-95° F., were decidedly destructive to potato seed. Mean soil temperatures above 90° at planting time resulted in marked reductions in stands. Seed piece break-down at high temperatures appears to originate as a physiological disorder which resembles blackheart in being associated with a high rate of respiration and a deficiency of oxygen in tuber tissues. Therefore, the planting of freshly cut seed pieces was found desirable in securing a satisfactory stand when the soil temperature was high or near the critical point. Definite relationship was observed between rate of sprouting and survival of seed pieces at high soil temperatures, with slow or delayed sprouting associated with low stands. Cut sets were preferred to whole tubers because they sprout quicker.

Refrigerated storage (50°) for spring-crop seed tubers was less desirable than cellar storage (70°-80°), because the cooler temperature caused seed to sprout more slowly after planting. Seed tubers harvested from the spring crop while immature (mid-June) were slower to sprout when planted and were less desirable for seed than tubers which reached full maturity in the field (July 1-6). Planting sprouted seed hastened sprout emergence and with year-old seed (from previous fall crop) greatly improved the stand. Multiple sprouting in this old seed was objectionable, for tuber size was reduced by competition between the several plants in each hill. Presprouted spring-crop seed might have some advantage over unsprouted seed in early plantings but not under better conditions in late plantings. Ethylene chlorohydrin treatment hastened sprouting of spring-grown seed and favored a good stand, especially when whole tubers were planted

throughout the usual planting season but with cut sets only when the plantings were made early (in July).

Time of planting factor as relating to soil conditions was found of major importance. Mortality of seed planted when the soil temperature was high usually was great. Prompt sprouting and emergence was favored in plantings made when the soil temperature was moderated by rainy weather. Irrigation aided in reducing soil temperatures between planting and establishment. Irrigations during post-emergence were especially helpful in stimulating uniformly rapid growth to assure satisfactory yields. Lower soil temperatures for plants irrigated by overhead spray compared to areas irrigated by furrows seemed to account for differences in favor of the spray method. Straw mulch at planting was beneficial in a year when drought and high temperature prevailed but detrimental in another season with heavy rainfall and lower temperatures. High ridges slowed up emergence and also resulted in faster drying of the soil, with consequent lower yields. Moderate to low ridges gave better results. Early sprouting of seed of varieties as Triumph and Warba, combined with their tendency for early maturity, made them more suitable for fall crop production than Cobbler, which has a longer rest period, sprouts more slowly, and requires longer to mature after emergence.

Growing fall-crop Irish potatoes, H. B. CORDNER (*Oklahoma Sta. Cir.* 102 (1942), pp. 15, figs. 5).—Suggestions for improving the fall potato crop, especially kind of seed, treatment of seed, and planting and care of crop, are based on experiments reported above.

Effect of seed treatment on nodulation of soybeans and peas, M. D. APPLEMAN. (Ill. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 6 (1941), pp. 200-203, figs. 2).—Satisfactory nodulation was produced upon pea and soybean plants grown from inoculated seed treated with Semesan, whereas Cuprocid prevented nodulation. Ceresan decreased nodulation on canning peas but not on soybean plants. All nodulation was of the lateral root type where seed disinfectants were used, although taproot nodulation was obtained upon untreated inoculated controls. The organisms were recovered from disinfectant-treated, inoculated seed after a lapse of 24 hr.

Soybean production in Missouri, B. M. KING and D. I. ALLEN. (Coop. U. S. D. A.). (*Missouri Sta. Bul.* 445 (1942), pp. 31, figs. 12).—Practical information is given on soybean varieties, methods of growing and harvesting soybeans for hay and seed, management of the crop in a rotation, and on the soil-fertility relations of the soybean crop. Soybean varieties variously adapted for grain and hay production in different sections of Missouri include for grain Illini, Dunfield, Chief, Scioto, Boone, Manchu, Ral soy, and Arksoy planted at normal time; Dunfield, Illini, Manchu, and Boone planted late or followed by small grain; and for hay Virginia, Wilson, Laredo, or grain types on very rich land.

[Variety tests with sugarcane in Puerto Rico in 1940] (*Puerto Rico Sta. Rpt.* 1940, pp. 51, 51-53).—Work by A. G. Kevorkian is reported on briefly.

A strain of Nancy Hall sweetpotato selected for color of flesh, N. D. PEACOCK, A. MEYER, and A. B. STRAND (*Tennessee Sta. Cir.* 80 (1942), pp. [4], figs. 2).—Strains of Nancy Hall sweetpotatoes selected for flesh color have yielded as high as, and probably surpassed, the common strain. Selection No. 103 appears to be a desirable dark (red-orange) color selection.

Vetch varieties for soil improvement and seed production in Alabama, H. R. ALBRECHT (*Alabama Sta. Bul.* 253 (1942), pp. [2]+15, figs. 6).—Vetches recommended for use in Alabama include hairy (*Vicia villosa*); smooth (*V. villosa* var.); Willamette, an improved strain of *V. sativa*; LaFayette and other hardy strains of monantha (*V. monantha*); woollypod (*V. dasycarpa*);

and *grandiflora* (*V. grandiflora*). All are well adapted to most sections of the State except Willamette, which has not proved satisfactory on the poorer, especially sandy, soils. Monantha, the best seed producer of the recommended vetches, is earlier than hairy vetch and has long produced excellent yields of green matter. LaFayette and other strains of monantha vetch now being developed by the station are hardy enough for use in Alabama. Willamette vetch, earlier and generally producing more seed than hairy vetch, is indistinguishable from common vetch but is more winter hardy. It is more vigorous than Alba, a white-flowered common vetch, but, like the latter, should be planted only on the better, well-drained soils. Woollypod closely resembles hairy vetch in growth habit and has about the same general adaptation. Auburn woollypod, now being multiplied by the station, is earlier than hairy vetch and a superior seed producer. Hungarian (*V. pannonica*), purple (*V. atropurpurea*), and most strains of common vetch are not recommended for green manures in Alabama. Augusta vetch (*V. angustifolia*) is useful whenever a volunteering vetch is required, but *grandiflora* vetch would be recommended instead were more seed available. Cultural methods and seed-harvesting practices, also based largely on station experiments, are outlined, with comments on insects and diseases attacking vetches and their control.

Classification of wheat varieties grown in the United States in 1939. J. A. CLARK and B. B. BAYLES (*U. S. Dept. Agr., Tech. Bul. 795 (1942), pp. 146, pls. 41, figs. 79*).—This publication is a revision of and supersedes Technical Bulletin 459 (*E. S. R., 74, p. 194*). Discussing a total of 212 varieties, it includes 47 new varieties and omits 74 which are no longer considered important.

The effect of terrace ridges on the production of winter wheat. H. J. HARPER. (Okla. A. and M. Col.). (*Soil Sci. Soc. Amer. Proc., 6 (1941), pp. 474-479, figs. 2*).—Effects of terrace ridges on the production of winter wheat in the southern Great Plains region were determined, 1932-34 and 1937-41, on Kirkland loam. On clay pan soils with slopes of less than 2 percent, the upper terrace channel must be drained during periods of excessive rainfall to prevent damage to wheat growing in the flooded area. Beneficial effects from runoff water collecting above a terrace ridge were observed when a deficiency of soil moisture restricted plant development on adjacent land not affected by additional water. Construction of contour-terrace ridges on shallow soils with slowly permeable subsoils does not provide a more favorable condition for crop production, since a reduction of the yield in the terrace channels will occur for several years, depending upon the rate of inter-terrace erosion. After the terrace ridge has reached a relatively stable condition, an area near the center of the ridge will produce less grain and straw than undisturbed soil in the terrace interval. Exposure of the crop growing on the terrace ridge during winter and a decrease in efficiency of torrential rainfall may be factors partly responsible for this condition.

Drill survey reveals need of seed testing as part of all-out food production effort. B. J. THORNTON (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 2, pp. 3-5, fig. 1*).—Tabulated results of surveys of alfalfa, red clover, sweetclover, barley, oats, and wheat seed being planted by Colorado farmers showed that 85 percent of all the seed samples taken contained noxious weed seeds. Much seed is planted without recleaning.

[Weed control in North Dakota] (*North Dakota Sta. Bmo. Bul., 4 (1942), No. 5, pp. 5-7, 18, fig. 1*).—These papers include a discussion of The Weed Problem, by O. A. Stevens (pp. 5-7), which contains a chart of the factors involved in weed control, and Two Important Factors in Weed Control, by E. A. Helgeson (p. 18).

HORTICULTURE

[Horticultural studies by the Indiana Station]. (Partly coop. U. S. D. A. et al.). (*Indiana Sta. Rpt. 1941, pp. 50, 53, 78-80, 81-83, 85-87, 88-90*).—Brief reports are presented on the following: Breeding tomatoes for resistance to *Fusarium* wilt and to defoliation diseases, both by R. E. Lincoln; breeding of sweet corn, by G. M. Smith; pruning of Golden Delicious apples and variety testing of peaches, plums, and prunes, all by C. L. Burkholder; soil management of peach and apple orchards and storage investigations, all by C. E. Baker; spraying and dusting investigations with the apple and spray residues on apples, both by Burkholder, D. L. Johnson, O. W. Ford, and E. D. Schall; breeding of rhubarb, by J. D. Hartman; tomato seed production, by E. C. Stair; factors involved in the quality of canned tomatoes, factors affecting quality and prices of mint oil, and freezing of fruits and vegetables, all by F. C. Gaylord and K. I. Fawcett; production and marketing of vegetables grown on muck soils, by N. K. Ellis and Gaylord, and on sandy soils, by Hartman and Gaylord; and tomato quality studies, by Hartman and Stair.

[Horticultural studies by the Puerto Rico Station] (*Puerto Rico Sta. Rpt. 1940, pp. 18-19, 22-23, 33-36, 38-43, 50-51, 53-65, figs. 14*).—Reports are presented on the progress of studies on the loss of viability in cinchona seeds and the sensitivity of cinchona seedlings to modifications in light intensity, both by W. Pennock; the productivity and growth of the Columnaris variety of coffee (coop. Puerto Rico Univ. sta.), by J. Guiscafré Arillaga; pruning of *Cananga odorata*, propagation and utilization of bamboo, culture and handling of rotenone-producing plants such as *Derris* and *Lonchocarpus* species, sweet corn production, cantaloup culture, stimulating effect of brewers' yeast on the growth of mangosteen seedlings, productivity of mangosteen trees, structure and development of mangosteen seeds, the introduction and distribution of new plant materials, by C. L. Horn; orchid culture, growing of rattan palms, handling of palm seeds for shipment, and the culture of *Aleurites trisperma* and *Hevea brasiliensis*.

Effect of temperature on the respiration rate and the respiratory quotient of some vegetables, H. PLATENIUS. (Cornell Univ.). (*Plant Physiol., 17 (1942), No. 2, pp. 179-197, figs. 7*).—Wide variations were observed in the respiration rate of 10 different vegetables, e. g. at 24° C. (75° F.) the initial rate of respiration of asparagus was 59 times that of the potato. No correlation could be established between respiration rates of different vegetables and their glucose content or carbohydrate reserves. The type of tissue appeared to play a dominant role in determining respiration rates. In general, respiration rate declined gradually with time at all temperatures. Respiratory quotients in general were highest soon after harvest, and with few exceptions smaller values were found at the lower temperature levels. It is suggested that the low respiratory quotients of certain vegetables, such as spinach and potatoes, may be due to the conversion of carbohydrates to organic acids.

Soil management practices for Peninsula vegetable growers, R. L. CAROLUS. (Va. Truck Expt. Sta.). (*Peninsula Hort. Soc. [Del.] Trans., 55 (1941), pp. 69-72*).—The importance of organic matter in the soil on the yield of white potatoes was shown in studies on 137 farms. On farms where the organic matter content was less than 1 percent there was a net loss. Profits increased as the organic matter increased above 1 percent, leading to the suggestion that potato production be not attempted where organic matter is less than 1.5 percent. Both sorghum and soybeans, uncut for hay, were effective in maintaining the production of potatoes. When kale and collards followed the potatoes, there was a beneficial residual effect of the green manures used on the potatoes. The functions of organic matter in the maintenance of soil fertility are discussed.

Growing vegetables with fertilizer in water, V. A. TIEDJENS and L. G. SCHERMERHORN (*New Jersey Stat. Bul.* 694 (1942), pp. 20, figs. 6).—Many vegetables were grown more efficiently by the application of fertilizers in water than as dry materials. Yields of tomatoes, sweetpotatoes, lima beans, snap beans, sweet corn, celery, and peppers were increased by the use of fertilizer solutions at the time of seeding or setting of the plants. Similar solutions in higher concentrations were used successfully for growing short-season crops to maturity. Applications of side dressing in the form of fertilizers in solution to long-season crops such as tomatoes, sweetpotatoes, and celery were more effective in general than were dry materials. The application of fertilizer in water may lower the unit cost of growing vegetables. The efficiency of fertilizers in water may be due to at least two factors: Greater availability of phosphoric acid and a reduction in injury caused by dry fertilizers. Materials and methods are discussed.

Vegetable varieties for Delta gardens, E. A. CURREY (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 5, p. 8).—Data are presented on the yields of beans, potatoes, tomatoes, eggplants, and peppers, and recommendations are given for variety selections for many other species.

The home vegetable garden, C. H. NISSLEY (*New Jersey Stat. Cir.* 428 (1942), pp. [28], figs. 15).—General information is presented on the planning, preparation, planting, and care of the home vegetable garden.

Anent the origin of sweet corn: *Zea mays*, L. var. *rugosa*, Bonaf., A. T. EAWIN. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 4, pp. 481-485).—A careful study of early colonial literature and other sources of information led to the conclusion that sweet corn, as now known in the United States, arose as a mutation of field corn in post-Columbian times. In support of this concept the author cites the discovery at the station of a single kernel of sweet corn as a mutant in a controlled series of pedigree cultures of dent corn.

Sweet Spanish onion bulb development most rapid in late August, test shows, A. M. BINKLEY and H. FAUBER (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 2, pp. 11-13, fig. 1).—Information is presented on the interrelation of day length and temperature on the bulbing of onions. The period of most rapid bulb development in the Sweet Spanish onion grown at Rocky Ford occurred between August 12 and September 1. The rate of top growth was more regular, except for a rapid growth preceding the beginning of extensive bulb development.

Bounty tomato in standard yield trials in 1940 and 1941, H. MATTSON (*North Dakota Sta. Bul.* 310 (1942) pp. 7).—This new tomato, developed by the station from a cross between Allred and Break o' Day, was introduced in 1941. Yield and grading data showed it to be definitely superior to other kinds ripening in the same season. In 1941 Bounty ranked first in yield of graded fruits from the beginning to the end of the harvest season at both Fargo, N. Dak., and Morden, Manitoba. Good reports were obtained also from various other localities.

New fertilizer practices and starter solutions for Peninsula tomatoes, C. H. MAHONEY. (Univ. Md.). (*Peninsula Hort. Soc. [Del.] Trans.*, 55 (1941), pp. 82-83).—With 500 lb. of a 4-12-8 fertilizer placed in two bands 4 in. deep and 5 in. on each side of the plant and a side dressing of 500 lb. applied 6 weeks after planting as the check treatment, three other forms of application gave significantly lower yields and six other methods gave significantly higher yields than the check. A hazard from the use of starter solutions was observed in the dry season of 1941. Two of three solutions produced definite injury to the plants, while the third, a balanced solution containing some phytohormones to induce rapid root formation, was definitely beneficial.

Tomatoes in the greenhouse, V. A. TIEDJENS and O. W. DAVIDSON (*New Jersey Stat. Cir.* 443 (1942), pp. [4]).—Information is presented on varieties,

soils, culture, pruning, pollination, use of growth-promoting substances to attain fruit setting, control of diseases and insects, etc.

[Leaflets on the home fruit garden] (*U. S. Dept. Agr. Leaflets 221 (1942), pp. 8, figs. 2; 222, pp. 8, figs. 2; 224, pp. 8, figs. 2*).—These leaflets list the best kinds and varieties of fruits and nuts for planting in the regions covered and set forth brief directions for their care. No. 221 covers the central Southwestern States; No. 222 the northern Great Plains, northern Mountain, and Intermountain States; and No. 224 the Pacific Coast States and Arizona.

Minnesota Fruit Breeding Farm.—Report for 1941, W. H. ALDERMAN and F. E. HARALSON. [*Minn. Expt. Sta.*]. (*Minn. Hort.*, 70 (1942), No. 6, pp. 106–107, 111–112).—Data are given on various improvements made possible by W. P. A. aid and on the status of fruit-breeding activities. Several promising new fruits are described.

Substitutes for nitrogen fertilizers in orcharding, A. E. MURNEEK and A. D. HIBBARD (*Missouri Sta. Cir. 236 (1942), pp. 7*).—The prospective shortage of inorganic N fertilizers due to war demands is pointed out, with suggestions as to the greater use of legumes, farm manures, activated sewer sludge, etc., to obtain the essential N. Certain organic materials, such as straw, cotton hulls, and sawdust, may have a detrimental effect due to the fact that the organisms which decompose such materials may take up most of the available N. The need of preventing losses by erosion and leaching is emphasized, and data are presented as to the cultural requirements of various legumes that might be grown in the orchard to provide N.

Studies in framework grafting of mature fruit trees, II–IV (*Jour. Pomol. and Hort. Sci.*, 19 (1942), No. 3–4, pp. 149–167, fig. 1; pp. 168–185, fig. 1; pp. 186–196, pls. 2, figs. 2).—Further contributions are presented (E. S. R., 72, p. 332).

II. *Apples*, R. J. Hilton.—The advantages of rapid reworking of mature fruit trees are discussed, and the principal methods of framework grafting, particularly cleft and bark grafting, are described. Methods of cleft and bark grafting were intermixed on the same tree, and, apart from differences in vigor of growth due to the different types of grafts, there was little evidence of interaction one with the other. The influence of fifteen 10-year-old frameworked intermediates on the vigor of Cox Orange Pippin scions was not markedly different in the first four seasons after grafting. Differences in fruit bud formation and cropping were more noticeable.

III. *Plums*, R. J. Hilton and T. N. Hoblyn.—Cleft- and bark-grafting methods, compared by grafting 7 scion varieties on 14-year-old Czar plum trees, indicated that cleft grafting was superior to bark grafting. There was considerable loss of scions in the first season from a summer gale, suggesting the need for some pruning of scions. There were differences in the growth and cropping of the 7 scion varieties, but the results were complicated by a large variation in successful unions. Tests of the intercompatibility of 23 scion varieties and of 3 intermediates yielded no clear-cut evidence of incompatibility in any of the 69 combinations, despite the fact that one of the intermediates and some of the scion varieties were known to be incompatible when worked on certain rootstocks.

IV. *A comparison of frameworked and topworked apple trees*, R. J. Garner.—A group of 13-year-old trees of Newtown Wonder, an apple susceptible to silver-leaf disease, was grafted with scions of Laxton Superb. Of the four methods employed, rind grafting was followed by the most breakage, most disease, and lowest yields. Frameworked trees lost no scions by breakage and suffered less from disease, with new scion growth considerably greater than in the rind-grafted

trees. The frameworked trees bore heavily in the third season and continued to produce more fruit than those top-worked by any other method.

Thinning fruits for vigor of the trees, quality of products, T. E. ASHLEY (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 5, p. 7).—Information is presented on the thinning of the fruit of the peach, plum, and apple.

Promising new apple variety is introduced (*Idaho Sta. Bul.* 244 (1942), pp. 20–21).—A promising new variety, Idared, developed by the station from a cross between Wagener and Jonathan, is described by L. Verner.

Rootstocks for apple trees, E. W. GREVE. (Univ. Del.). (*Peninsula Hort. Soc. [Del.] Trans.*, 55 (1941), pp. 36–38).—In 1929, an orchard of five varieties—Yellow Transparent, Grimes Golden, Delicious, Stayman Winesap, and Rome Beauty—half on their own roots and half on French crab seedlings, was established at the Delaware Experiment Station. Half the trees in each group were never pruned and half were pruned regularly. Yield data presented for unpruned Grimes Golden, the most productive of all five varieties, showed the seedling-rooted trees to have been the more productive. Observations are presented on the behavior of Blaxtayan and Gallia Beauty trees growing on six different Malling rootstocks.

Progress toward a more scientific basis for orchard fertilization, D. BOYNTON. (Cornell Univ.). (*N. Y. State Hort. Soc. Proc.*, 87 (1942), pp. 192–198).—Studies of the relation between leaf N, fruit color, and yield made in a large number of New York McIntosh apple orchards showed that as the percentage of leaf N increased the proportion of orchards producing fruit averaging 50 percent or more color at harvest decreased markedly. However, more high-N orchards produced good crops than did low-N orchards. In the 1.8- to 2.0-percent N range, there appeared to be fair chances for both good production and good color. In the case of McIntosh nursery trees grown in the greenhouse and supplied with different concentrations of K, it was noted that trees having sufficient K with no marked luxury consumption had about 1.7 percent of leaf K. In one instance, leaves had 4.5 percent of their dry weight as K without showing any injury. K deficiency symptoms were evident on trees receiving less than 50 p. p. m. of K. Prune trees required more K than did apple trees for vigorous growth, with the peach and cherry apparently intermediate. Since leaf analyses reflect the actual capacity of the tree to accumulate K, the author believes them to be a more reliable index to the K situation than soil analyses.

The effects of spray applications and heavy soil applications of borax on apple trees and fruits, L. P. LATIMER. (Univ. N. H.). (*N. H. Hort. Soc. Jour.*, 6 (1942), No. 1, pp. 66–79).—Internal cork, a physiological disease, was found more or less prevalent in New Hampshire apple orchards, with the McIntosh unfortunately one of the susceptible varieties. Droughty conditions accentuated the tendency to injury. In the dry summer of 1941 trees were sprayed in the first part of July with a solution of 2 lb. of borax to 100 gal. of water, an amount equivalent to about 0.25 lb. of borax per tree. With the exception of one tree, no corky fruit was found, while on certain unsprayed control trees the fruit was severely affected.

In another experiment Golden Delicious trees were supplied in June 1940 through the soil with borax at rates of 0.5, 1, 2.5, 5, 10, and 20 lb. per tree. No visible injury to fruit or tree was observed that season. In 1941 without further applications severe injury was observed in the 10- and 20-lb. trees and occasional injury in the 5-lb. group. Analyses of soil collected in November 1941 beneath the trees gave evidence that much of the borax applied in the heavier treatments had either become unavailable or had leached. There was an increase in boron content in the fruit up to the maximum amounts applied. In general, Golden

Delicious apples contained more boron at any given rate of application than did Red Delicious. In the case of boron sprays there was some evidence that it is safer to spray after the leaves have attained maturity.

Lime sulphur vs. mild sulphur, A. F. YEAGER and C. R. CROSS. (Univ. N. H.). (*N. H. Hort. Soc. Jour.*, 6 (1942), No. 1, pp. 62-65).—Over a period of 7 yr. Northern Spy trees which had been sprayed continuously with flotation sulfur averaged 503 lb. of fruit per year as compared with 352 lb. for comparable trees sprayed with lime-sulfur. Data on McIntosh trees showed 314 lb. for the flotation sulfur group and 269.8 lb. for the lime-sulfur group. Results in favor of milder forms of sulfur were also obtained in a commercial McIntosh orchard. Here the individual fruits in the mild sulfur block were actually smaller than those in the lime-sulfur block, suggesting that factors other than fruit size are concerned with yield differences.

The compatibility of fruit drop chemicals, K. J. KADOW and S. L. HOPPER-STEAD. (Univ. Del. et al.). (*Peninsula Hort. Soc. [Del.] Trans.*, 55 (1941), pp. 32-34).— α -Naphthaleneacetic acid was found compatible with Black Leaf 155, Genecide, phenothiazine, and derris. Observations in commercial orchards indicated the possibility of using the sodium salt of α -naphthaleneacetic acid or α -naphthaleneacetic acid and amide in combination with Black Leaf 155. There was no evidence that the addition of the materials designed to reduce fruit dropping had any detrimental effect on the insecticidal values of the materials used. On the other hand, sprays containing lime reduced markedly the effectiveness of the fruit drop chemicals. Weathered deposits of lead arsenate, copper sulfate, and lime did not affect the effectiveness of fruit drop sprays.

Blossom sprays to take apples off and harvest sprays to hold them on, M. B. HOFFMAN. (Cornell Univ.) (*N. Y. State Hort. Soc. Proc.*, 87 (1942), pp. 172-179).—Attempts in 1940 to limit the fruit set of Wealthy trees by spraying the blooms with solutions of Elgetol showed that the condition of the tree was an important factor in the results. With neglected weak trees one application of 0.1-percent solution reduced the set about one-half, while with very vigorous trees one application when one-half of the flowers were open had little effect. In 1941 on 17-year-old very vigorous and heavily budded Wealthy trees those sprayed with 0.2-percent Elgetol when in full bloom produced almost as large apples as did hand-thinned trees. The spray did not thin the fruits as uniformly as did hand thinning, but a little supplemental thinning would have accomplished this objective.

In the case of naphthaleneacetic acid sprays applied to vigorous 16-year-old McIntosh trees to prevent preharvest dropping, the trees sprayed on September 1 dropped 7.8 percent of their fruits in the next 8 days as compared with 22.9 for the control trees. A second spray applied September 5 reduced the drop to 5.3 percent. Under the warm weather conditions of 1941 the spray gave good results with Baldwin and Northern Spy as well as with McIntosh.

A useful abnormality of the pollen in a pear, P. T. THOMAS (*Nature [London]*, 149 (1942), No. 3771, pp. 168-169).—In crosses in which the Beurré Bedford pear was used as the pollen parent, very few good seeds were obtained. A study of the pollen showed that, following normal meiosis, cell walls failed to develop between the four haploid nuclei, with the result that the pollen mother cells were transformed into giant four-nuclear pollen grains. Five types of mature grains were observed, all of which germinated readily and with more vigor than pollen from normal varieties. In crosses with diploid and tetraploid varieties, Beurré Bedford gave rise to various types of polyploids and should serve as a means of synthesizing a wide range of new polyploid pears.

Refrigerated gas storage of fruit.—V. Conference, Doyenné du Comice, and Williams' Bon Chrétien pears, F. KIDD and C. WEST (*Jour. Pomol. and Hort. Sci.*, 19 (1942), No. 3-4, pp. 243-276, pls. 5, figs. 4).—Detailed experiments were conducted with pears held under various conditions with respect to concentrations of CO₂ and O₂ and temperature. In general, it was established that a very considerable extension of storage life may be obtained by the use of atmospheres containing lower percentages of O₂ (2.5-10 percent) and higher percentages of CO₂ (5-10 percent) than are normally present in air. Temperatures as low as 31.5° F. were safely used with pears, this fruit being apparently more tolerant to low temperature than are most varieties of apples. Pears should not be wrapped in oiled papers. Upon removal from storage pears ripened at moderate temperatures attained higher quality than those ripened at lower or higher degrees. Pears picked prematurely failed to develop optimum dessert quality.

Concentration of growth hormone and fruitfulness in the Montmorency cherry, F. G. GUSTAFSON (*Natl. Acad. Sci. Proc.*, 28 (1942), No. 4, pp. 131-133).—Blossom buds that were about to open or were in the process of opening were collected from Montmorency cherry trees selected and grown by the Michigan Experiment Station for their high- and low-bearing tendencies. The buds of the fruitful trees had a growth hormone content more than three times as large as that of buds of the barren trees. Apparently there was a positive correlation between fruit setting and the growth hormone content of the ovaries of the flowers.

Strawberry production in southeastern Iowa as influenced by varieties, fertilizers, and cultural practices, P. MINGES, T. J. MANEY, and B. S. PICKERT (*Iowa Sta. Res. Bul.* 295 (1942), pp. 505-564, figs. 5).—Of 45 standard varieties and a number of seedlings tested for adaptation to southeastern Iowa, Blakemore and Howard 17 proved to be the most satisfactory kinds for commercial use. For home plantings Beaver and Narcissa were found desirable for early maturity, and Catskill, Dorsett, and Dunlap for midseason. In general the early-maturing varieties were the better producers, with evidence that strawberry varieties are rather sensitive to local environmental conditions. Among fertilizing materials, stable manure alone increased yields consistently. In one season phosphorus applications increased size and also yields to some extent. The modified matted-row type of culture was apparently the most advisable system of planting. In soil management studies need was found for proper drainage and cultivation, rotations with legumes, maintenance of organic matter, correction of soil acidity, and the use of phosphate fertilizers. Renovation of beds by mowing and burning caused serious damage in years of drought, and such measures are not advised except when sufficient rain has fallen to insure prompt resumption of growth. Much trouble from weeds could be avoided if the wheat straw used for mulching was spread during the summer in long piles away from the strawberry patch. In this process much of the weed and grain seed was shaken out of the straw.

The uneven ripening of Concord grapes: Chemical and physiological studies, J. E. WESTER and F. B. CROSS (*Oklahoma Sta. Tech. Bul.* 13 (1942), pp. 48, figs. 12).—Failure of all the berries in clusters of the Concord grape to color was found a serious handicap to the culture of this variety in Oklahoma. This bulletin summarizes the results of numerous experiments designed to determine the underlying causes of failure and to find treatments that would improve the situation. Unfortunately no successful treatment was revealed. The use of N fertilizer slightly improved color development, while shading and irrigation at the approach of normal maturity proved harmful. Results of

analyses showed rather conclusively that uneven coloring is associated with a partial lack of sugar in the berries that fail to color properly. Color developed satisfactorily only when the total sugar content exceeded about 7 percent. Girdling, while slightly increasing the amount of sugar in the juice, did not give increases commensurate with the labor and difficulties involved. Unlimited leaf area gave slightly better coloring than did 10 leaves per cluster. Minerals in the seeds of colored and green berries did not vary greatly, and no correlation could be established between seed content and color development. The results suggest that in areas where uneven coloring occurs, it is desirable to replace the Concord with other varieties which do color satisfactorily.

Substitutes for Concord grapes in Oklahoma, F. B. CROSS and J. E. WEBSTER (*Oklahoma Sta. Cir. 103 (1942)*, [pp. 6]).—Uneven ripening, a condition that is directly associated with low sugar content, renders the Concord grape variety of doubtful value in Oklahoma. No cultural practice was found which would improve the situation, hence the station recommends a number of other varieties that could be profitably used to replace the Concord. Methods of grafting Concord and other undesirable varieties to better kinds are suggested.

Root distribution of young avocado trees on bench terraces, M. DONNELLY. (Univ. Calif. and U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 101-109, fig. 1).—Near San Juan Capistrano, Calif., four types of bench terraces, (1) preconstructed, (2) level basin, (3) Reddick, and (4) Javanese, were used for the growing of avocados under essentially dry-land conditions. The maximum root penetration was on a Reddick terrace on a southerly exposure. The maximum lateral spread was observed in Ambrose silty clay loam on a level-basin terrace on a northerly exposure. The heavier soils caused a reduction in number and an increase in size of roots. In poorly aerated compact soil zones, even with soil moisture and other conditions favorable, there were few or no roots. Root growth on the heavy soils on south exposures on preformed terraces was extremely poor and only fair on north exposures on preformed terraces of Ambrose silty clay. Roots grew well in Ambrose clay on the Javanese bench with northerly exposures. On southerly Reddick bench terraces root growth was fair to good in Ambrose clay and excellent in Altamont silt loam. On the level-basin terraces root growth was excellent.

Moisture studies under citrus using tensiometers, L. A. RICHARDS and M. R. HUBERTY. (U. S. D. A. and Univ. Calif.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 73-79, figs. 4).—Records were taken over 1 yr. on soil moisture tensiometers placed at eight depths down to 15 ft. under two 11-year-old navel oranges budded on sweet orange, with one tree irrigated twice as often as the other. Plants grew and extracted water from soils over a tension range from 0 to about 15 or 16 atmospheres at the wilting point. The range for tensiometers was, however, from 0 to somewhat less than 1 atmosphere. Under the lightly irrigated tree all tensiometers at depths of 4 ft. or more stayed on scale all year. Under the tree with heavy irrigation, all tensiometers of 3 ft. or more stayed on scale all summer. The data provided information on the rate and depth of moisture penetration, on moisture storage and on the rate of root extraction at various depths, and on root zone leaching.

Measurements on hydrocyanic acid absorbed by citrus tissues during fumigation, E. T. BARTHELOMEW, W. B. SINCLAIR, and D. L. LINDGREN. (Calif. Citrus Expt. Sta.). (*Hilgardia [California Sta.]*, 14 (1942), No. 7, pp. 373-409, figs. 9).—Based on fumigation experiments with Valencia orange leaves and fruits in a gastight metal fumatorium and in regulation canvas tents in the orchard, information is presented on some of the factors influencing the absorption and retention of HCN by citrus tissues. The concentrations of gas

remained nearly constant in the fumatorium but varied greatly in the tents in the orchard. Considerably more HCN was absorbed by fruits preconditioned overnight at 43° F. before fumigation than by those held at 80°. Green fruits absorbed an average of 5.4 times as much HCN as did mature fruits. Under laboratory conditions the absorption of HCN was retarded by the oil spray, but this did not occur in the orchard. In the laboratory none of the fruits was injured by HCN, while in the orchard about 6 percent of the oil-sprayed trees were damaged. That irrigation may affect absorption of HCN was shown in a greater gas absorption by leaves and fruits of trees that had been recently irrigated than by those which had not been irrigated for sometime. Fruits sprayed with water and a spreader and fumigated at once absorbed less gas than did dry fruits. In comparable trials with inland- and coastal-grown green oranges the coastal fruits were more severely injured despite the fact that in one case the inland fruits absorbed more HCN. Green fruits fixed or chemically changed absorbed HCN so that it could not be recovered and determined by the usual methods. Despite the fact that leaves and fruits absorbed approximately the same amounts of HCN whether fumigated during the day or night, more injury followed day treatments. Greater day injury appeared to result from the effect of sunlight in raising temperature and influencing the physiological condition of the tissues. In the experiments recovered HCN was retained by mature leaves for at least 60 hr., by green fruit for 35-40 hr., and by mature fruit for 20-25 hr. The stomata were apparently not important in governing the rate of entrance of HCN into citrus leaves and fruits.

Rebuilding cold-injured lemon trees, F. F. HALMA. (Univ. Calif.). (*Calif. Citrog.*, 27 (1942), No. 8, pp. 220, 233, figs. 2) —Severely injured 5-year-old Eureka lemon trees were successfully restored, and 5 yr. after the operation were yielding as well as, if not slightly better than, replants made shortly after the freeze. The cost of rebuilding the trees was less than that of replanting them. In the case of trees so badly injured that the entire lemon trunk had to be removed, requiring the rebudding of a rootstock sprout, the results were of dubious value both from the standpoint of expense and recovery.

The native persimmon, W. F. FLETCHER, revised by H. P. GOULD (*U. S. Dept. Agr., Farmers' Bul.* 685, rev. (1942), pp. [2]+22, figs. 17).—This is a revision of the edition of 1915 (E. S. R., 34, p. 43). General information is offered on the distribution of the persimmon, growth and fruiting habits, methods of propagation, planting, pruning, cultural care, control of diseases and insect pests, use of the tree in erosion control, utilization of the fruits (including recipes), etc.

Care of top-worked pecan trees, C. H. RAGLAND (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 6, p. 7, figs. 3).—The removal of competing sucker shoot growths and the provision of support for rapidly growing scions are recommended and procedures discussed.

Delayed foliation of pecan trees in Arizona, C. W. VAN HORN. (Ariz. Expt. Sta. and U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 87-94, figs. 2).—Records taken in the Yuma, Salt River, and Safford Valleys showed the most uneven breaking of buds or delayed foliation in areas with the warmer winter periods. Delayed foliation was practically always shown by the opening of the buds on the northeast side of trees several days before those on the southwest side. Greater absorption of heat by the buds on the southwest side of the trees is believed to account, in part, for this difference. In 1940-41 the percentage of possible sunshine at Yuma was somewhat below the average, and symptoms of delayed foliation were much less pronounced than usual. A dormant DNO spray (2-4-dinitro-6-cyclohexylphenol in oil) was found rather effective in stimulating initiation of growth within certain

pecan varieties at Yuma. At Safford, where there was apparently ample natural chilling, the DNO treatment had no stimulating effect. Varieties differed somewhat in their response to DNO treatments, due apparently to their different chilling requirements. Shoot growth, size of leaves, percentage of shoots forming pistillate blossoms, percentage of blossoms to set nuts, and yield of nuts were other measures of response to different conditions.

Some aspects of dichogamy and pollination in pistache, W. E. WHITEHOUSE and C. L. STONE. (U. S. D. A.). (*Amer. Soc. Hort. Sci. Proc.*, 39 (1941), pp. 95-100, figs. 2).—An analysis of blooming records taken at Chico, Calif., over 4 yr. indicated that more than one male is probably needed for the effective pollination of a given female variety. The mere overlapping of blossoming periods was not adequate to insure a set of fruit because all the pistillate flowers are not receptive during the entire blooming period. Under favorable conditions for pollination no important differences were noted in the set obtained with different pollens whether the pollens was intraspecific or interspecific. The primary consideration appeared to be the provision of abundant pollen at the proper time.

Rubber from western desert plants (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 2, pp. 2, 11).—Comments are presented upon the rubber situation and the possibility of utilizing various rubber-producing native plants, including rabbitbrush and milkweeds.

Hedge plants for the northern Great Plains, T. K. KILLAND (U. S. Dept. Agr., *Farmers' Bul.* 1898 (1942), pp. 11-13, figs. 11).—In connection with information on the use of hedges, planting materials, handling and planting, pruning, and care the results of extensive tests with different plants conducted at Mandan, N. Dak., are discussed. Green ash, boxelder, and Siberian elm were found best for high screens or shelters. For medium-high general-purpose hedges common buckthorn, Siberian pea-tree, Russian-olive, and Chinese lilac were found desirable, but buckthorn could not be recommended because it is a host for crown rust of oats. Peking cotoneaster, *Ribes diacanthum*, and flowering plum are recommended for dwarf to medium-high hedges. Vanhoutte spirea, *Spiraea bumalda* var. *rosea*, and Japanese barberry were promising for untrimmed hedges, but all suffered during protracted droughts.

The distribution of North American rose species, T. M. LITTLE. (U. S. D. A.). (*Amer. Rose Ann.*, 1942, pp. 37-49, figs. 9).—With the aid of maps, information is presented on the distribution of native rose species in North America.

Trenching and soil-mixtures: Their effect on rose-production, E. I. WILDE and R. P. MEAHL. (Pa. Expt. Sta.). (*Amer. Rose Ann.*, 1942, pp. 95-98).—In experiments with Grenoble roses grown in eight different soil mixtures, the best growth was recorded in soils to which manure had been added. The most luxuriant growth, the longest stems, and the greatest number of blooms were produced by plants growing in one-half loam, one-fourth manure, and one-fourth hyperhumus. The average production of flowers over a 3-year period increased as the depth of trenching was increased up to the 24 in. used. However, loss by winter injury in most cases increased with depth of trenching and with other conditions that favored luxuriant growth.

FORESTRY

[Forestry studies by the Indiana Station] (*Indiana Sta. Rpt.* 1941, pp. 73-74, 74-76).—Reports are presented on the following studies: Marketing Indiana woodland products, by R. C. Brundage; tree volume tables for Indiana, by A. M. Herrick; and wood lot management, management of the experimental

nursery, and air movement as affected by windbreaks, all by D. DenUyl.

Effect of planting methods on survival and growth of plantations on well-drained sandy soils of central Wisconsin, S. A. WILDE and A. R. ALBERT. (Wis. Expt. Sta. et al.). (*Jour. Forestry*, 40 (1942), No. 7, pp. 560-562, fig. 1).—A number of planting methods were investigated on an exposed area of a depleted outwash sandy soil in central Wisconsin. Jack and red pine seedlings were planted in shallow and deep furrows, on top of the furrow slice, in slits without scalping, and in holes using a spade and supplying additional humus soil. Planting in deep furrows gave the best and slit planting the poorest results, both in survival and in rate of growth. The direction of the furrow exerted no significant effect.

Fertilizer trials for improved establishment of shortleaf pine, white ash, and yellowpoplar plantings on adverse sites, W. H. CUMMINGS (*Jour. Forestry*, 39 (1941), No. 11, pp. 942-946).—On test plantings of shortleaf pine, white ash, and yellow poplar seedlings made on acid soils of low fertility in southern Ohio, fertilizers did not notably stimulate height growth in any of the three species, although in some instances each of the species responded to fertilizer. The results suggested the need for further tests in which shortleaf pine would be treated with fertilizers low in N, high in P_2O_5 , and very low in K, with supplements of acid peat. White ash should be tested further with fertilizers high in N, low in P_2O_5 , and very low in K, with supplements of acid peat. Yellow poplar appeared to need materials with medium N; very low in P_2O_5 , and low in K, with dolomite limestone filler.

Producing seedlings of eastern red cedar (*Juniperus virginiana* L.), M. AFANASIEV and M. CRESS (*Oklahoma Sta. Bul.* 256 (1942), pp. 21, figs. 5).—The cause of delayed germination in the seed of the eastern red cedar was found to be a dormant embryo. Stratification at a low temperature was required to complete afterripening, but the time needed varied with different lots of seed. The drying of afterripened seed reduced germination and induced a period of secondary dormancy. However, a shorter duration of stratification was needed to overcome the secondary dormancy. Freezing of afterripened seed for 4 weeks lowered germination only to a small extent. The optimum temperature for germination of afterripened seed was 50° F., and 60° and 70° almost as good. Above 70° the rate of germination was retarded markedly. A temperature of 100° was almost prohibitive to germination and growth of the resulting seedlings. Within the pH range of 4.4 to 8.4, germination occurred about equally well. Cleaned seed was held at 41° for 1 yr. without loss of viability, and dry berries were held at room temperature for a similar period without reducing germination. Holding afterripened seeds in pure oxygen for 24 hr. lowered their viability.

The Johnson fir, O. V. MATTHEWS (*Jour. Forestry*, 40 (1942), No. 7, pp. 579-581, figs. 3).—A description is presented of a variant form of *Abies grandis*, here designated as *A. grandis* Lindl. f. *Johnsoni*, forma nova.

Growing of white pine on the Yale forest near Keene, New Hampshire, R. C. HAWLEY and R. T. CLAPP (*Yale Univ. School Forestry Bul.* 48 (1942), pp. [4]+44, pls. 10, fig. 1).—A descriptive account is given of the Yale Forest, an area used as a field laboratory for scientific research and a demonstration of effective forestry practices. White pine is the principal tree grown on the forest because of its high value and its natural adaptation to the soil and climate. The hurricane of 1938 destroyed virtually all the timber over 40 yr. of age.

Information is given on methods of harvesting merchantable wood and timber, of establishing new stands, and upon cultural operations, such as pruning, thinning, and insect control, required in the development of a profitable crop.

A forty-year old planted longleaf stand, C. R. Ross (*Jour. Forestry*, 40 (1942), No. 7, pp. 581-584, fig. 1).—Measurements are presented on a small plantation (1.15 acres) of longleaf pine established 40 yr. ago on a very light sandy soil in Lee County, S. C. Despite the fact that the soil was poor and that the needles had been annually raked from the area, the trees had made a very reasonable growth.

The naturalization of Scotch pine, northeastern Oneida County, N. Y., H. H. YORK and E. W. LITTLEFIELD (*Jour. Forestry*, 40 (1942), No. 7, pp. 552-559, figs. 3).—Plantations established in the northeastern part of Oneida County, N. Y., between 1870 and 1888 were found to be reproducing abundantly and the species to be spreading gradually. The sandy soil of the area was apparently well suited to Scotch pine, and the abandoned farm lands favored its establishment.

Pinus thunbergii: A successful exotic on the North Atlantic coast, E. W. LITTLEFIELD (*Jour. Forestry*, 40 (1942), No. 7, pp. 566-573, figs. 3).—Information is presented on the introduction and present distribution of the Japanese black pine, now recognized as a very valuable tree for coastal forestation and landscape use. In hardness it compares favorably with other pines, having endured temperatures as low as -20° F. in western New York during the cold winter of 1933-34. The seedlings are, however, rather sensitive to low temperatures and require mulching. This pine is notable for its saline tolerance and resistance to European pine shoot moth and other insects. The species has limited forestry value and may find its maximum use as a protective tree and for park and landscape purposes.

Effects of certain soil treatments on the development of loblolly pine nursery stock, L. K. ANDREWS (*Jour. Forestry*, 39 (1941), No. 11, pp. 918-921).—In experiments conducted in a forest tree nursery in the sand-hill region near Hoffman, N. C., a significant benefit in the growth of loblolly pine seedlings was obtained from the addition of a heavier textured soil or of organic matter. Root: shoot ratio by weight was reduced as a result of such treatments, but the root system had a larger number of small branching rootlets. The most desirable planting stock was obtained when both organic material and a concentrated fertilizer containing a high percentage of phosphoric acid was added to sandy soil.

Effect of stocking and seed on nursery development of eastern white pine seedlings, L. H. REINEKE (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 7, pp. 577-578).—Observations on eastern white pine seedlings grown from two lots of seed, one of unusually large seed and one approximately average, indicated that the density of the stand in the seedbed has a material effect on the development of the plants. Seed size influenced the magnitude of the modifications due to density. The value of reduced density was shown in the increased sturdiness of the seedlings as reflected in larger stems and taproot diameters and more numerous and longer lateral roots. The time required to grow stock to a desired size may be reduced by decreasing the seedbed density.

Polyembryony in seeds of southern pines, M. L. NELSON (*Jour. Forestry*, 39 (1941), No. 11, pp. 959-960).—During germination tests with southern pine seeds conducted in 1936-37 several instances were found in which there was more than one embryo present, especially in *Pinus palustris*. Polyembryony was most often characterized by two seedlings, one large and one rather small and usually imperfectly developed. Occasionally the two seedlings were of equal size. To a lesser extent polyembryony was observed in seeds of *P. caribaea* and *P. echinata*.

The necessity of zinc for *Pinus radiata*, M. E. SMITH and N. S. BAYLISS (*Plant Physiol.*, 17 (1942), No. 2, pp. 303-310, figs. 3).—Plants produced from seeds collected from a tree growing in a locality where rosetting is known to be of frequent occurrence were grown in a zinc-free culture solution. There was no mycorrhiza present. Deficiency symptoms were observed within 3 to 4 mo. These symptoms were slow growth; inwardly folded apical needles, which later exhibited a yellow mottling, followed by bronzing; and short, stiff dark-green secondary needles in unopened fascicles. The root tips may be distinctly swollen.

Strength properties of Chinese elm, A. J. PANSHIN. (Mich. State Col.). (*Jour. Forestry*, 40 (1942), No. 7, pp. 564-565, fig. 1).—On the basis of strength properties, rapidly grown Chinese elm wood was found equal to both American and slippery elm wood except in static bending where the Chinese elm was noticeably inferior to the native American species in stiffness. Information is presented on the anatomical features of Chinese elm wood.

Comparison of logging costs with clear-cutting and several intensities of selective thinning in northern Minnesota jack pine, C. B. SCOTT. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 7, pp. 544-551, figs. 5).—The results of a detailed study of the costs involved in the clear-cutting and partial cutting of jack pines are discussed.

Filters for penetrating atmospheric haze, G. M. BYRAM. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 7, pp. 530-532, figs. 5).—A polarizing screen or combination screen and red filter was found to penetrate haze to a much greater degree than any kind of color filter used alone. The underlying principles, the construction, and the operation of the apparatus are discussed.

DISEASES OF PLANTS

[Plant disease work by the Idaho Station] (*Idaho Sta. Bul.* 244 (1942), pp. 18, 39-42, 47-49, 50).—Notes are presented, by H. K. Schultz, K. H. W. Klages, J. M. Raeder, H. C. Kirkpatrick, W. J. Virgin, D. Murphy, E. C. Blodgett, J. E. Kraus, and J. L. Toevs, on the influence of diseases on growth and yield of wheat, barley, and oats, including tests of varieties, crosses, and selections; prevention of the spread of bacterial ring rot of potatoes on the cutting knife and description of early plant symptoms of infection; tests of potato seedlings for virus resistance; decay in cut potato seed pieces exposed to hot dry conditions; extensive occurrence of *Fusarium* wilt of potatoes; effect of moisture supply on jelly end rot of potatoes; resistant crosses and selections of beans (coop. U. S. D. A.); bacteria causing poor germination of pea seed; tomato hybrid showing promise for curly top resistance; low storage temperatures preventing carrot rots; virus-induced western X disease and wart disease of peach trees; arsenic toxicity to peach trees; fire blight of pear; and bacterial gummosis of sweet cherry and apricot.

[Plant disease studies by the Indiana Station] (*Indiana Sta. Rpt.* 1941, pp. 48-49, 49-50, 51-53, 85, fig. 1).—Brief reports of progress are included on studies of a new disease of peppermint in Indiana shown to be caused by *Verticillium* sp., by R. C. Baines; eradicant sprays for apple scab, by Baines and C. L. Burkholder; control of peppermint anthracnose by clean plowing, by Baines and R. H. Wileman; the taxonomy of the plant rust fungi, by G. B. Cummins; types of potato scab and their control in Indiana muck soils, by R. W. Samson; and *Fusarium* wilt of China aster, by E. R. Honeywell.

[Phytopathological studies by the Puerto Rico Station] (*Puerto Rico Sta. Rpt.* 1940, pp. 5-11, 53, figs. 3).—Progress reports are given on studies by A. G. Kevorkian and E. Hernandez Medina of *Fusarium datatatis vanillae* root rot as a limiting factor in vanilla production in Puerto Rico, including data on two districts where no commercial losses from it have occurred, a blast disease due to

an undetermined fungus, and the limited capacity of hold-fast roots of vanilla to utilize nutrients; and by Kevorkian on the susceptibility of the sugarcane variety Mayaguez 338 to the *Fusarium* of pokkah boeng disease.

Diseases of plants reported in Texas since 1933, G. E. ALTSTATT. (Coop. Tex. Expt. Sta.). (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1942, Sup. 135, pp. 37-50*).—This check list involves those plant diseases found since the publication of the previous list by Taubenhaus and Ezekiel (*E. S. R., 70, p. 486*), including new host plants subject to *Phymatotrichum* root rot reported subsequently to the list, by the same authors, previously noted (*E. S. R., 76, p. 642*). The arrangement is alphabetical by Latin names of hosts, in each case followed by common name of disease and cause.

The Plant Disease Reporter, [June 1 and 15, July 1-15, 1942] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 26 (1942), Nos. 10, pp. 227-244; 11, pp. 245-275, figs. 3; 12-13, pp. 277-304, figs. 2*).—The following are included:

No. 10.—An annotated list of the parasitic fungi (28 genera, including at least 73 recognized species and varieties and a total of 191 host-pathogen combinations) on cereals and other grasses in Klickitat County, Washington, by R. Sprague; the cereal disease situation in Kansas, by C. O. Johnston; early leaf rust development in eastern Nebraska in 1942, by M. W. Felton; strawberry spring dwarf situation on Cape Cod, by O. C. Boyd; and brief notes on the increase of potato virus diseases in New Hampshire last year, tobacco seedbed diseases in Maryland, wet weather and plant diseases in New Hampshire this spring, and apple scab in Maryland.

No. 11.—A disease of wheat newly recorded for this country—yellow spot disease (*Helminthosporium tritici-vulgatis*) of wheat in New York State, by M. F. Barrus; *Helminthosporium tritici-vulgatis* on wheat in Maryland, by A. G. Johnson; notes on diseases, decays, and disorders of tobacco in Puerto Rico during the 1941-42 season, by H. H. Foster, M. Garcia Fortuño, and G. Irizarry Rubio; additions to the host index of fungi of Mount Shasta, California, II, by W. B. Cooke (*E. S. R., 84, p. 60*); brief notes on control of silvertop of fescue by burning, wheat leaf rust in South Dakota, a wood-destroying fungus (*Stereum rugosulaculum*) on sweet gum, tupelo, and black gum, rust (*Uredo sapotae*) on sapodilla in Florida, and various plant diseases observed in Pennsylvania; and host-parasite check-list revision (*Rosmarinus* to *Rubus*), by F. Weiss.

No. 12-13.—Tomato tip blight (caused by a strain of the spotted wilt virus) found in West Virginia, by J. G. Leach and A. Berg; tomato tip blight (distributional data meager, and it is suggested that pathologists be on the lookout for it); two *Cercosporas* (*Cercospora papaveri* and *C. atropae*) newly reported in the United States; peony anthracnose found in Illinois, by D. B. Creager and G. H. Boewe; dieback (*Gloeosporium?*) of safflower in Texas, by H. Rich; tests with two varieties of roses for resistance to black spot, by E. W. Lyle and G. E. Altstatt; Spergon for sweetpotato treatment—limited test in Arkansas, by V. H. Young; a tobacco seedbed disease survey in Massachusetts, 1942, by W. H. Davis; reports on late blight of potato on Long Island and in Pennsylvania and Wisconsin, and on losses caused by potato diseases in the Hastings Section, Florida, in 1942; reports on diseases of small grains in Pennsylvania, South Carolina, Texas, Kansas, central and southern California, and Arizona, and cereal rusts in southwestern Virginia, West Virginia, and South Dakota; reports on diseases of fruit crops, including red stele of strawberry on Pathfinder and Aberdeen varieties, apple scab in Rhode Island, and fruit diseases in New York and Pennsylvania; brief notes on weed control by plant diseases in Kansas, diseases of vegetables and ornamentals in Pennsylvania, bacterial wilt and smut on sweet corn, flax

diseases in southeastern Kansas, and leaf spots on bluegrass and alfalfa in Pennsylvania; and host-parasite check-list revision (*Sabal* to *Salix*), by F. Weiss.

Index to Supplements 130-132, N. W. NANCE (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1941, Sup. 133, pp. 105-126*).

A polysaccharide produced by the crown-gall organism, F. C. McINTIRE, W. H. PETERSON, and A. J. RIKER. (*Wis. Expt. Sta. et al.*). (*Jour. Biol. Chem., 143 (1942), No. 2, pp. 491-496*).—"The isolation and characterization of a polysaccharide produced by the crown-gall organism are presented. The polysaccharide appeared to be homogeneous as judged by analysis of diffusion data and by constant rotation through reprecipitation and fractionation of both the original material ($[\alpha]_D^{25} = -9^\circ$ to -10° , in water, $c=2$) and its acetylated product ($[\alpha]_D^{25} = +56^\circ$ to $+58.5^\circ$, in chloroform, $c=1$). Hydrolysis of the polysaccharide gave only *d*(+)-glucose as indicated by specific rotation, iodometric titration, and yield of glucobenzimidazole. A shift in rotation during hydrolysis indicated a predominance of β linkages, while the rate of hydrolysis and the shape of the hydrolysis curve suggested that the inner ring structures were exclusively pyranoside. The molecular weight calculated from sedimentation velocity and diffusion constants was $3,600 \pm 200$, which corresponds to about 22 anhydroglucose units per molecule."

Fungicidal properties of 2,4-diaminodiphenylamine and other substituted diphenylamines, M. C. GOLDSWORTHY, E. L. GREEN, and H. L. HALLER. (*U. S. D. A.*). (*Jour. Agr. Res. [U. S.], 64 (1942), No. 11, pp. 667-678*).—In laboratory tests 2,4-diaminodiphenylamine was found to be fungicidal against *Sclerotinia fructicola* and *Glomerella cingulata*. Small scale orchard tests also indicated this material to be of some value for control of apple scab and peach scab but not of cherry leaf spot. As an orchard spray, its principal deficiency lies in its high solubility in water, which affects its lasting qualities. The material did not injure apple, pear, quince, plum, apricot, cherry, peach, or bean under field or greenhouse conditions. Of a group of closely related diphenylamines tested in the laboratory only, 2,4-diamino-2-phenyldiphenylamine, diphenylamine, 4-nitrodiphenylamine, 4-chlorodiphenylamine, and diphenylparaphenylene were toxic to fungi in various degrees, but none approached that of 2,4-diaminodiphenylamine. Except for the first two, none of the compounds tested were injurious to Red Kidney bean.

An outline for the treatment of vegetable and field crop seeds, J. A. PINCKARD (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 6, pp. 3-4, 6*).—This contribution describes methods and materials which have proved valuable to others in their attempts to prevent losses among seedling plants. Following general directions for seed treatments, the specific data are taken up alphabetically under particular fungicides and tabulated under host plants and their diseases.

Influence of cultural factors on alfalfa seedling infection by *Pythium debaryanum* Hesse, W. F. BUCHHOLTZ (*Iowa Sta. Res. Bul. 296 (1942), pp. 569-592, figs. 3*).—*P. debaryanum* was found to cause rapid direct or indirect necrosis of germinating alfalfa seed or seedlings and to retard development by primary and secondary root girdling and root tip necrosis, resulting in partial or occasionally complete losses of seedling stands and in dwarfed plants with root systems inadequate to carry the plants through high-temperature and low-soil-moisture periods. Seedling infection tended to be more prevalent in acid than in neutral Iowa soils. Lime proved ineffective for control in laboratory tests but gave small though sometimes inconsistent increases in stands on acid soils in certain field plots. Seed treatment with ethyl mercury phosphate was effective in the laboratory and in some field plantings in 1935, but in subsequent field tests

it was not. Early plantings usually yielded better stands than later spring plantings. Deep plowing was effective for control in 1935, but less markedly so in 1937 and 1938. The fungus appeared to be more abundant in the surface soil than below 4 in. in depth, and deep plowing turned up the relatively uninfested soil for the seedbed. Red clover, alsike clover, and white Dutch clover appeared more resistant than alfalfa in greenhouse plantings in infested soil, and the first two yielded much better stands than alfalfa in unplowed fallow infested soil in single-plat field plantings in 1935. Sweetclover stands in the same plantings were also better than the alfalfa stands. The general indications from this study are that it may be possible to improve alfalfa seedling stands by planting early, to a limited extent by liming acid soil, and by deep plowing to expose uninfested soil for the seedbed.

The factorial interpretation of anthracnose resistance in beans, C. F. ANDUS and B. L. WADE (U. S. Dept. Agr., Tech. Bul. 810 (1942), pp. 29, figs. 6).—The inheritance of resistance to three physiologic forms of *Colletotrichum lindemuthianum* (β , γ , and δ) was studied in intervarietal bean crosses, 15 parent varieties and selections being used in 80 combinations. Field and greenhouse inoculations were made on 145 first-, about 32,600 second-, 108,000 third-, and a considerable number of fourth-generation plants. In crosses of resistant \times tolerant and resistant \times susceptible, resistance was always dominant. In two crosses of tolerant \times susceptible, susceptibility was dominant in the F_1 and subsequent generations. A few resistant \times resistant crosses segregated a proportion of susceptible, and certain susceptible \times susceptible crosses segregated a proportion of resistant, plants. It is suggested that such crosses offer the quickest way to ascertain the existence of heterogeneity of genotypes in host species.

Monohybrid and dihybrid ratios were obtained with all three fungus forms, and trihybrid ratios also were obtained with two forms. A system of 10 genes in 3 allelomorphic series, involving both duplicate and complementary genes for resistance, 1 dominant gene for susceptibility, and gene interactions at 3 points, is proposed as the simplest mendelian hypothesis coordinating all the data for β and γ anthracnose. A simpler explanation (3 independent pairs of genes) would suffice for δ , but the more complex gene system is not thereby excluded. The hypothesis calls for 11 susceptible and 25 resistant parental genotypes of which 2 susceptible and 5 resistant were apparently realized in the β data alone. In certain cases differences were noted in the proportion of susceptible segregants as between greenhouse and field, between second and third generations, and between reciprocals. It is considered that 1 gene could be responsible for all the irregularities. It could be presumed that the same genes are operating in respect to all three fungus forms, but that they exercise a modified or reversed function, depending on the form to which the host is exposed. Although the genotype of any individual is strictly speaking unchangeable, it would be necessary to express the disease reaction genotype by different symbols expressive of the host-parasite interaction. On this basis the number of genes involved in anthracnose reaction is not necessarily proportional to the number of physiologic forms of the pathogen. Linkage was observed in one cross between red seed-coat color and susceptibility to β and γ anthracnose.

Cercosporiella eyespot of Kentucky bluegrass, R. SPRAGUE. (Oreg. Expt. Sta. coop. U. S. D. A.). (Phytopathology, 32 (1942), No. 8, pp. 737-738, fig. 1).—*C. poagensis* n. sp. was found to cause a distinctive straw-color to light-brown lesion with a definite yellow halo or eyespot effect on living leaves of *Poa pratensis* in Oregon.

Some pathogenic fungi occurring in the seed of red and subterranean clover, S. J. P. CHILTON. (U. S. D. A.). (Phytopathology, 32 (1942), No. 8,

pp. 738-739).—Subterranean clover seed (6 lots) and red clover seed (49 lots) were surface-sterilized with 1-1,000 HgCl₂ followed by a Ca-hypochlorite solution and plated on potato-dextrose agar medium. *Pleospora herbarum*, *Stemphylium sarcinaeforme*, *Ocerospora zebrina*, and a sterile black fungus of large mycelium called the "black patch" fungus by the Kentucky Station (1834) were obtained from the red clover seed. A much higher fungus incidence was found in macroscopically blemished than in sound seed. *Sclerotium bataticola*, *Rhizoctonia solani*, and *Fusarium* were isolated from one lot of subterranean clover seed.

Relative susceptibility to Pythium root rot of twelve dent corn inbreds, C. ELLIOTT. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 12, pp. 711-723, figs. 8).—The plants tested were grown in sand, watered with nutrient solution, and inoculated by adding agar cultures of *P. arrhenomanes* to the sand after the plants were well established. Weekly growth measurements of inoculated and control plants and weights of tops and roots indicated that some inbreds were susceptible to root rot, some were resistant, and others were intermediate in reaction. Inbred Ia. L317 proved most resistant and inbred C. I. 1 most susceptible. The fungus interfered to some extent with the growth of all the inbreds by destroying the fine feeding roots.

Cottonseed treatments in New Mexico, G. STATEN (*New Mexico Sta. Bul.* 290 (1942), pp. 32, figs. 7).—Tests with acid-delinted and undelinted cottonseed and the effects of various dust treatments on them are reported. Significant correlations of percentages of floating seed and of germination were found, but some types of immature seed could not be removed by cleaning. Considerable improvement in the germinability of low-quality seed by cleaning was noted, but little improvement in that of good-quality seed could be expected. Normal dosages of several commonly used dust treatments, including New Improved Ceresan, 2-percent Ceresan, and Spergon, were found to decrease the rate of germination slightly. Overdosages of the first delayed germination seriously, and toxic effects on seedlings were noted. Dust-treated seed was held under three different storage conditions for over a year without injury to germinability. New Improved Ceresan and 2-percent Ceresan gave excellent protection against seed rotting in cold soils for both delinted and undelinted seed, and Spergon was almost as good as either of these treatments. Sanosced and Cuproclde afforded some protection but were comparatively ineffective. No difference was found in the ability of acid-delinted and undelinted seed to resist rotting in cold soil. Spergon, New Improved Ceresan, and 2-percent Ceresan, in the order named, proved effective in increasing seedling emergence, preventing pre-emergence damping-off, increasing survival stands, reducing postemergence damping-off in some cases, and increasing survival stands of healthy plants in soils infested with *Rhizoctonia*. Cuproclde and Sanosced were ineffective, and none of the treatments were very satisfactory, in preventing infection after emergence of the seedlings. In field-plat trials acid-delinted seed produced slightly (not significantly) higher yields than undelinted seed. Both New Improved Ceresan and 2-percent Ceresan were effective in increasing the survival stand of plants in the field but did not significantly increase the yield of a full field stand. Use of a good dust treatment is recommended regardless of whether delinted or undelinted seed is planted. Some of the dusts are toxic to man, so care should be used to prevent inhaling or allowing them contact in quantities with the skin.

Observations on soil conditions and a foot and root-rot disease of darso during 1940, H. F. MURPHY. (*Okla. Expt. Sta.*). (*Okla. Acad. Sci. Proc.*, 21 (1941), pp. 79-80).—Field observations indicated the disease (identity not yet definitely established) to be more prevalent on areas with soil moisture

favorable to darso, and in rotation tests it was most severe on plats which had been limed. Soil reaction appeared to be another factor involved. The general results of the season's observations served to stress the complexity of this disease situation.

Preliminary investigations on mechanical injury in flax seed, J. R. MACHACEK and A. M. BROWN (*Phytopathology*, 32 (1942), No. 8, pp. 733-734).—Tests on a large number of samples indicated that in most cases the seed was severely damaged by cracking of the seed coat. This occurred during threshing, and, being almost invisible to the naked eye, did not lower the market grade. When such seed were planted they usually failed to germinate, thus causing thin stands and much lowered yields. Seed treatment with Ceresan or Half-ounce Leytosan prevented this loss.

Breeding for disease resistance in oats, H. C. MURPHY, T. R. STANTON, and F. A. COFFMAN. (Iowa Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 1, pp. 72-89, figs. 2).—The major oats diseases in the United States are said to be loose and covered smuts and crown and stem rusts, and among the minor ones occasionally causing considerable damage are blast (non-parasitic), *Fusarium* blight, halo blight, stripe blight, *Helminthosporium* leaf blotch, and *Pythium* root necrosis. Estimates reported in *The Plant Disease Reporter* (U. S. D. A.), 1919-38, showed an annual loss from smuts of about 3.5 percent (about 40 million bushels) of the oats crop of the United States. The estimated losses from rusts for this same period are 2 percent (nearly 23 million bushels) for crown rust, and 1.2 percent (about 14 million bushels) for stem rust. Recent statistical studies of the effects of crown and stem rusts on oats production indicate that these estimates may be much too low.

For the smuts, Victoria is highly resistant to all known races, Markton and Navarro are highly resistant to all but certain rare races, and Bond and Black Mesdag have adequate resistance under most field conditions. For crown rust, Bond and Victoria are highly resistant to all except certain rare and little known races. Rainbow, Alber, and Capa may be classed as only moderately resistant, but this resistance affords considerable protection to the crop in many sections. For stem rust, Richland, Iogold, and Rainbow are highly resistant to all races of apparent economic importance, showing susceptibility only to certain rare races, the old White Tartar oat has furnished adequate resistance under certain field conditions, and Jostrain (Joanette strain) can be classed only as moderately resistant.

By crossing within this group of varieties, many new strains have been developed with resistance to the smuts only, to stem rust only, to smuts and stem rust, to smuts and crown rust, and to the smuts, stem rust, and crown rust in combination with high yield and quality. In winter oats, strains combining disease resistance and winter hardiness also have been evolved. Among the new agronomic smut-resistant varieties are Carleton, Bannock, Marida, Huron, Uton, Fulgrain, and Fulton. Vanguard is the only comparatively new stem-rust-resistant variety that has been named. Certain selections from a cross of Hajira × Joanette are outstanding because of their apparent resistance to all races of stem rust. Among the recently developed smut- and stem-rust-resistant named varieties are Nakota (hull-less) and Hancock. The number, however, with resistance to smut and crown rust is much larger, and a list of 13 is given. The newly developed and named varieties resistant to the smuts, crown rust, and stem rust include Marlon, Boone, Tama, and Vicland. Combining resistance to the more important minor diseases with that already available to the smuts and rusts does not seem impossible. Definite varietal resistance has been reported for oats blast, halo blight, bacterial stripe blight, *Pythium* necrosis, etc. There are 28 references.

Alteration of potato starch grain structure under the influence of disease. D. B. O. SAVILE (*Amer. Jour. Bot.*, 29 (1942), No. 4, pp. 286-287, figs. 6).—The occurrence of malformed starch grains in potato tubers affected by various fungus, virus, or environal disorders and associated nuclear abnormalities are described. It is suggested that the formation of these grains is attributable to an altered physical state of the leucoplasts.

A stem-end rot of potato tubers caused by *Rhizoctonia solani*. F. S. THATCHER (*Phytopathology*, 32 (1942), No. 8, pp. 727-730, figs. 2).—In this "punky" stem-end tuber rot, found to be due to *R. solani*, disease development depended on the prevalence of conditions tending to retard wound-periderm formation, and low temperatures and high rainfall shortly before harvesting were field conditions favoring it. Symptoms could be duplicated by keeping inoculated tubers at 5° C. in a moist chamber or in water-saturated sand at 15°-20°. Tracheids provided the main avenue of progress through the tuber.

Further studies on the temperature relations of sclerotial isolates of *Rhizoctonia solani* from potatoes. E. L. LECLERC, L. H. PERSON, and S. B. MEADOWS. (U. S. D. A. and La. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 8, pp. 731-732).—The optimum temperature for radial growth of 63 isolates from sclerotia on potato tubers was 25° C.; for 2 crown rot and 2 dry rot isolates from sugar beets it was 30°. These results confirm those previously reported (E. S. R., 85, p. 67).

[Potato scab] (*Amer. Soc. Agron., Com. Fert. Min.*, 7 (1941), pp. 4-17).—Included are replies to a questionnaire on potato scab in the Northeastern States, presented by J. A. Chuka, and discussion and summary of a potato scab survey in the Southern States, by H. T. Cook.

Potato virus disease studies with tuber-line seed plots and insects in Maine, 1927 to 1938. D. FOLSOM (*Maine Sta. Bul.* 410 (1942), pp. [3]+215-250, pls. 4, fig. 1).—Potato seed-plot work begun in 1921 and based on virus-disease discoveries at about that time has been continued by the author with emphasis in recent years on aster-cloth cages, shown to be efficient in excluding insect vectors, and tuber-unit planting, the helpfulness of which was demonstrated. At first it was hoped that healthy tuber-lines could be increased in size in comparatively isolated open-field plats without appreciable virus infection. The ultimate failure of this method led to the second phase of the studies, in which an attempt was made to determine the frequency of passage of virus diseases into healthy tuber-line plats. Only in this way could field-to-field transmission be adequately studied, since tuber-line plats were the only kinds initially free of infection. A third phase concerned the effects of various conditions on disease invasion of seed stocks in tuber-line plats, including latitude, earliness of planting and development of plants, size of seed plat, and so-called isolation on the passage of disease into the plats and on the increase of disease within them.

At Highmoor Farm (1927-32), 21 tuber-line seed plats grown in the open were invaded by one or another of the virus diseases present in other potatoes on the same farm, in 15 of 75 possible chances. On 74 different farms (1933-38), 114 tuber-line seed plats were also grown, in each case with a follow-up inspection of the progeny during the succeeding year to disclose what virus diseases had been brought into the seed plat by insects and to what extent. The detailed results are presented and discussed. The cages excluded virus diseases perfectly when erected before the plants emerged. In the open, mosaic and leaf roll usually increased in spite of roguing or came in where previously absent. Earlier planting and earlier development of the plants in the seed plat increased the possibility of success in disease

control. The certification proximity rule did not prove a safe guide as to amount of disease entering healthy plants. Giant-hill was found not to spread. Two aphids (*Macrosiphum solanifolii* and *Aphis abbreviata*) transmitted leaf roll under some experimental conditions, whereas four other insects tested, as well as root contact in the soil, did not. Insect counts in the field indicated the latter group of insects (flea beetles, Colorado potato beetle, apple leaf-hopper, and tarnished plant bug) to be unimportant in the spread of the virus diseases. There are 25 references.

More potato research results in stronger endorsement of zero tolerance in seed (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 2, pp. 17-18*).—A brief report of progress on the station studies of potato ring rot, by W. A. Kreutzer, D. P. Glick, J. G. McLean, and G. M. List, is presented, with the conclusion that "zero tolerance probably will prevent increase of ring rot in Colorado seed; 1 or 2 percent tolerance will not." Laboratory tests have indicated that ring rot bacteria can be transmitted from diseased to healthy plants by grasshoppers, blister beetles, and Colorado potato beetles, though no actual record of field spread by insects has been obtained. Recommendations for cut seed treatment and cleaning up of foundation-stock tubers are made.

Washing and sterilizing potato bags, W. E. BRENTZEL (*North Dakota Sta. Bimo. Bul., 4 (1942), No. 5, p. 20*).—Contaminated bags were found to spread ring rot, but those washed a few minutes in a small amount of soda ash, followed by boiling in a chlorine bleach and final rinsing in cold water, did not. The process removed all brand marks and shrunk them slightly, but did not materially injure the strength of the fiber.

Scurf, black rot, and stem rot of sweet potatoes, R. H. DAINES (*New Jersey Stas. Cir. 437 (1942), pp. 8, fig. 1*).—Because of the similarities in these three serious diseases of different causation, certain of the measures providing relief from their attacks are also similar. Descriptions and control measures are presented.

Bacterial leafspots of Pennsylvania tobacco.—I, Occurrence and nature of the microorganism associated with wildfire, J. J. REID, J. NAGHSKI, M. A. FARRELL, and D. E. HALEY (*Pennsylvania Sta. Bul. 422 (1942), pp. [2]+36, fig. 1*).—The following conclusions are drawn from studies of a large number of green-fluorescent gram-negative bacteria isolated from seedbed soils as well as from plant material derived from seedbed and field:

Extensive serological tests with single-cell isolations indicate the organism associated with the wildfire disease to be identical antigenically with the common saprophyte, *Pseudomonas fluorescens*. Similar studies lead to the same conclusion with respect to *Phytomonas angulata*, *P. primulae*, and *P. cerasi*. Due to the inability to maintain cultures of *P. vignae* and *P. syringae* in the S phase, it has thus far not been possible to compare these species antigenically with *Pseudomonas fluorescens*, but the data obtained suggest a similar relationship. A study of the transformation of the capsular antigenicity of *P. fluorescens* on normal clover plants permitted the assumption that the antigenic specificity of the wildfire organism in the M phase is a reflection of capsular changes occurring during the reproduction of the organism as a harmless epiphyte. Seedbed steaming as practiced in Lancaster County does not result in eliminating the bacteria associated with the leaf spot diseases of tobacco. On the contrary, they are more prevalent afterwards than before. In this area tobacco as a rule is produced in the presence of leaf spot organisms, inasmuch as those associated with such diseases have been found in all seedbeds examined and on most plant material from seedbed and field. Since they have been found on most normal as well as diseased tobacco plants, it is believed that

the appearance of the disease cannot be attributed to their mere presence, but to some other factor or factors. There are 26 references.

Tobacco mosaic in Ontario and Quebec, G. H. BECKLEY (*Sci. Agr.*, 22 (1942), No. 8, pp. 465-478).—The virus was found capable of overwintering in the soil, thus necessitating crop rotation to avoid primary field infections from that source. Evidence is presented that mosaic may be readily spread during transplanting, especially if the help use tobacco in any form. Cultivation proved one of the most important agencies of spread, and roguing was demonstrated to be of material aid in checking it. In topping a field of tobacco where mosaic is present it is advised that the healthy plants be handled first.

Three strains of cucumber mosaic occurring on tobacco in Ontario and Quebec, J. H. H. PHILLIPS (*Canad. Jour. Res.*, 20 (1942), No. 6, Sect. C, pp. 329-335, pl. 1).—From diseased material collected in Ontario and Quebec three virus strains were isolated and designated Nos. 1 to 3. "Strain 1 most closely resembled typical cucumber mosaic in its symptoms on tobacco and tomato. Strain 3 produced a similar type of mottle to strain 1, but was generally more severe and consistently produced severe leaf narrowing on tomato. Strain 2 was easily recognized by its ability to produce necrotic rings on the inoculated leaves of burley tobacco varieties and the tendency of affected plants to recover from the initial symptoms. The three strains retained their identity through a large number of serial inoculations. Investigations demonstrated that a severe type of streak was produced when tomato plants were inoculated with a combination of cucumber mosaic virus (strain 3) and potato X virus. Unlike tobacco mosaic virus, the virus of cucumber mosaic was unable to survive over winter in plant tissue in the soil. Field observations indicated that dissemination of cucumber mosaic in tobacco plantings was effected by insect vectors."

Infectivity of extracted, unpreserved tobacco mosaic virus retained 28 years, H. A. ALLARD. (U. S. D. A.). (*Science*, 95 (1942), No. 2471, p. 479).—The tests reported appear to indicate that the retention of virulence in extracted, unpreserved sap depends on the type of fermentation which gains control under certain conditions.

Varietal reaction to bunt in the western wheat region of the United States, C. S. HOLTON and C. A. SUNESON. (U. S. D. A. and Ariz., Calif., Idaho, Mont., Oreg., Utah, Wash., and W. Va. Expt. Stas.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 1, pp. 63-71).—The reactions of 83 varieties and hybrid selections of winter wheat to bunt were determined by growing them in uniform nurseries at 11 localities in the western United States and at Kearneysville, W. Va., and inoculating with spores from commercial wheat fields near each nursery or from a composite of collections from commercial wheat fields in the entire Pacific Northwest. None proved bunt-free at all stations, although 36 varieties averaged less than 10 percent and 7 less than 1 percent. In the production of 26 of the 27 most resistant hybrid selections 5 resistant varieties were involved. In 8 of the 12 nurseries the majority of the infected varieties and selections had less than 10 percent of bunt. The prevalence and distribution of race groups of the bunt fungi were indicated by the reactions of the host testers included in the nurseries each year. One or more of the most virulent races appeared to be fairly prevalent throughout the western region.

Studies on the pathogenicity of *Fusarium* species associated with root rot of wheat, C. L. JOHNSTON and F. J. GREANEY (*Phytopathology*, 32 (1942), No. 8, pp. 670-684).—Pathogenicity tests in the greenhouse were made with *F. culmorum*, *F. oxysporum aurantiacum*, *F. avenaceum*, and *F. equiseti*, the *Fusarium* species most commonly isolated from root-rotted wheat and from

grain soils in Manitoba. Of the 24 isolates of *F. culmorum* studied, only one proved distinctly pathogenic to both seedling and adult wheat plants and no marked pathogenicity was exhibited by any of the other species used. Field tests with these fungi gave essentially similar results. In the greenhouse, soil moisture content did not influence the virulence of these organisms on wheat seedlings, but, in general, the intensity of infection increased with an increase in soil temperature. In greenhouse pot tests, *Trichoderma lignorum* and *Pyronema confluens*, two common soil inhabitants, suppressed the pathogenicity of a very virulent isolate of *F. culmorum*, whereas *Penicillium intricatum* and *Aspergillus flavipes* did not. The virulence of *F. redolens*, a very weak pathogen, was not influenced by the presence of *P. intricatum* and *A. flavipes* in the soil. There are 32 references.

An unusually virulent race of wheat stem rust, No. 189, G. GARCIA-RADA, J. VALLEGA, W. Q. LONGERER, and E. C. STAKMAN. (Minn. Expt. Sta. coop. U. S. D. A. et al.). (*Phytopathology*, 32 (1942), No. 8, pp. 720-726, figs. 2).—In Peru, an extraordinarily virulent race of *Puccinia graminis tritici* (now numbered 189 in the Stakman-Levine key) was isolated from heavily infected Khapli emmer. This is the only race known to cause heavy infection on all the differential wheat varieties used in identifying physiologic races. Furthermore, it attacks a number of hitherto resistant varieties in the field, as shown by the fact that Khapli emmer, Hope wheat, and *Triticum timopheevi* were all severely rusted by it in Peru. Thus far the race has been found only in Peru, and it seems improbable that it has been in the United States, since Khapli emmer is one of the differential varieties used in identifying races and has been inoculated with all the collections identified during the past 20 yr. Moreover, Khapli has proved resistant when grown in the field in many places in this country since 1908. The origin of race 189 is unknown, but it occurs in an area in which rust is known to develop on native barberries and it seems likely that it may have resulted from an unusual combination of genes following sexual fusion on that host. This combination having been made, it seems not unlikely that it may be made again in other regions. It is also possible that spores might be blown from Peru to other areas where this rust does not now occur, and it is even possible that this race might be disseminated northward and across the equator, though this possibility may be somewhat remote.

Microbiological and nutritional factors in the take-all disease of wheat, C. R. STUMBO, P. L. GAINEX, and F. E. CLARK. (Kans. Expt. Sta. coop. U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 64 (1942), No. 11, pp. 653-665, figs. 4).—In wheat-cropped soils of similar texture, differences were not found in numbers or kinds of micro-organisms in take-all infested and noninfested field areas, nor was there apparent any correlation between levels of available P and incidence of infection. In greenhouse tests wheat straw and inorganic fertilization applied to the soil at planting time failed to control the disease. With superphosphate fertilization at seeding time and inorganic N slightly in excess of the amount calculated as necessary for plant growth applied during the growing season, the severity of take-all was reduced by increasing the amounts of superphosphate. With both available-P and nitrate-N content maintained at suitable levels, successful control was obtained even though significant differences in microbial numbers were not encountered.

Causes, effects, and control of defoliation on tomatoes, J. G. HORSFALL and J. W. HEUBERGER (*Connecticut [New Haven] Sta. Bul.* 456 (1942), pp. 181-223, figs. 9).—In this 12-season study, particular emphasis was placed on solving the seeming paradox of reduced yields from sprays despite disease control, the problem being attacked by studying plants in different stages of disease

and the varying control obtained by different sprays. Though the primary cause of defoliation in the Northeast is *Alternaria solani*, it is not a vigorous parasite and optimum conditions for infection include crowded plants, leaf maturity, heavy fruit load, above normal rainfall and dew, and shading. A special study of fruit load and age of tissues to susceptibility appeared to indicate that any factor such as pruning, low N nutrition, or heavy reproduction tends to increase susceptibility. This proved especially true of fruit load. The longer the plant remained free of fruit the longer it also remained free of *Alternaria*, and the more fruit set the more susceptible it became. Extensive studies of the effects of disease and of spraying gave no evidence that they influence fruit maturity, i. e., ripening. Many factors such as disease, dwarfing, and defoliation from sprays reduce fruit load, and in turn these of course affect the number of fruits picked and so the shape of the picking curve.

In studying the disease-controlling properties of fungicides, a protective coefficient was devised for reducing the variance among tests due to inoculum potential, spraying technic, method of recording disease, and kind of disease. It is the quotient obtained by dividing the amount of disease on plants sprayed with a standard by that on the test material, and it is based on the assumption that as extraneous factors affect the unknown they also affect the standard. The tests on copper-containing bordeaux substitutes rate them as good, intermediate, and poor. Those in the first group appeared to be yellow copper oxide, bordeaux, red copper oxide, Compound A, Coposil, and Tenn. 34. Those in the "Intermediate" group were Basicop, Hydro 40, and Cuprocide 54. Those in the poor group were Metrox, ZO, Cupro K, and hydrated cupric oxide. Timing of tomato sprays proved of critical importance in economical control of defoliation. To reduce spray injury to the plants, applications should be delayed as long as is compatible with satisfactory disease control. Consideration of all the data at hand suggests that in Connecticut the first spray should be applied just as the plants break over. Coverage is important in spraying ground tomatoes, since the lower and inner leaves are most susceptible to defoliating fungi. It is suggested that the spray nozzle should be as large as possible, so that the spray stream will be hard enough to push aside the outer crown of leaves. There are 45 references.

A micrurgical study of crown gall infection in tomato, E. M. HILDEBRAND. ([N. Y.] Cornell Expt. Sta.). (*Jour. Agr. Res.* [U. S.], 65 (1942), No. 1, pp. 45-59, figs. 7).—Tomato plant-juice extract proved excellent for culturing *Phytoplasma tumefaciens*; and single bacterial cells grew readily in microculture therein. The sap in the wound cavity liberated from the plant cells injured in the wounding operation also supported growth of the bacteria. Isolations from wounds about 5 days after inoculation and before symptoms appeared showed that the original single cells had multiplied into thousands of individuals in the wound sap. When injected into the cells of tomato stems the crown gall organism failed to induce gall formation and ordinarily failed to survive inside the cells, indicating the living cell interior to be an unfavorable medium for it.

Single bacterial cells induced gall formation when introduced into needle-puncture wounds of various sizes. The lower percentage of infections resulting from single-cell inoculation as contrasted with that from inocula consisting of larger numbers was attributed to chance distribution favoring the larger numbers reaching the proper position for multiplication and cell stimulation. Tiny wounds in the stem, involving one or more epidermal cells, approximated the minimum size for infection, and only a small percentage of such wounds became infected when the inoculum was applied by gently rubbing the stem surface with a polished needle moistened with a bacterial suspension. With

identical inocula shallow stem wounds (about 2-12 cells deep) were less efficient than deep wounds as infection courts. This result is attributed to chance distribution of the bacteria and to the larger amount of wound sap favoring the larger wounds as infection courts.

Ordinarily the ultimate size of the gall was correlated with depth of wound but was independent of size of initial inoculum. The largest galls observed resulted from inoculating deep stem wounds regardless of whether the inoculum was one or a large number of bacterial cells. The relations (1) between tiny wounds, tiny galls, and few bacteria, (2) between shallow wounds, small galls, and more bacteria, and (3) between deep wounds, large galls, and many bacteria were verified by isolation experiments. There are 18 references.

A survey of the genus *Lycopersicon* for resistance to the important tomato diseases occurring in Ohio and Indiana, L. J. ALEXANDER, R. E. LINCOLN, and V. WRIGHT. (Coop. Ohio and Ind. Expt. Stas.). (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1942, Sup. 136, pp. 51-85*).—At the Ohio and Indiana Experiment Stations 448 (including 5 species) of the Bureau's introductions of members of the genus *Lycopersicon* have been tested and classified for disease reactions in an effort to locate sources of resistant germ plasm for use in tomato breeding programs. Tests have been made for resistance to practically all the important tomato diseases occurring in the north central region of the United States, and these data are brought together in this contribution. In some species high resistance was found to *Fusarium* wilt, leaf mold, *Septoria* and *Alternaria* leaf blights, common tobacco mosaic, and bacterial spot, and resistance to *Colletotrichum* ripe fruit rot was also indicated. No marked resistance to bacterial canker or bacterial wilt was found. Wide differences in the severity of cracking of red-fruited introductions were observed. What appeared to be resistance to red spider was noted in one species. There are 11 references.

The effects of certain mosaic-inducing viruses on the tomato crop under glass, I. W. SELMAN (*Jour. Pomol. and Hort. Sci., 19 (1941), No. 1-2, pp. 107-136, pls. 3, figs. 9*).—The diversity of the symptom pictures induced by one or the other of tobacco virus 1 and of two strains of tomato mosaic viruses (and also of cucumber virus 1 successfully inoculated into a few tomato plants) at different times of the season and in the same plant is pointed out. Enations were associated with the cucumber virus and the two strains of tomato mosaic, but not with the tobacco virus, and their origin is discussed. There was evidence that they can be induced in infected plants allowed to develop freely after subjection to hardening conditions. Light brown streaks appeared on one plant inoculated with the tobacco virus. Severe wilting was noted in the plants inoculated with one of the tomato strains at the appearance of symptoms. For the tobacco and both tomato viruses, high partial correlation coefficients existed between the mean number of daylight hours during which the plants were exposed to 70° F. or over and the percentage showing a mild light and dark green leaf mottle only. Controls produced significantly more flower buds on trusses 2-5 than did early-infected plants, the greatest difference being in the fourth truss. A significant reduction in number of fruits was occasioned by early infection. The percentages of flower buds producing fruits was lowered by early infection in all cases, as was the total yield of ripe fruit from five trusses. Early infection induced very slight increases in the percentage of blotchy fruit. A very small reduction in the weekly rate of leaf production was recorded with infected plants during the 9 weeks following inoculation, and a marked though temporary check was noted at the time the symptoms appeared. Infection significantly reduced the weekly height incre-

ment of the main stem during the first 9 weeks of the experiment. The time of appearance of symptoms is considered to be the most critical stage in the metabolism of an infected plant, and the importance of this stage in devising control methods is pointed out. There are 22 references.

Handbook of virus diseases of stone fruits in North America, E. M. HILDEBRAND, G. H. BERKELEY, and D. CATION. (Coop. Cornell Univ. et al.). (*Michigan Sta. Misc. Pub.*, 1942, pp. 76).—As noted in the foreword, by V. R. Gardner, the gradually increasing seriousness of the virus disease problem in stone fruits has been a matter of growing concern, and at the suggestion of several pathologists a conference to consider the question was held at Michigan State College in September 1941. One of the outgrowths of this meeting was the selection of a committee to assemble and organize both published and unpublished data on the nomenclature, symptoms, host range, geographic distribution, and other characteristics of the virus diseases of this group of trees. The present handbook is the result, its purpose being to make immediately available an up-to-date summary of the information known about stone fruit virus diseases, including certain ones not hitherto reported.

Four new virus diseases of stone fruits found in peach mosaic study in Colorado, E. W. BODINE, J. H. NEWTON, and W. A. KREUTZER (*Colo. Farm Bul.* [*Colorado Sta.*], 4 (1942), No. 2, pp. 6-10, figs. 4).—Brief histories and descriptions of the course and symptoms are given for the golden net virus disease of apricot, plum, and peach; rasp-leaf of cherry; ring spot of apricot; and X-disease of peach.

Indexing cherry yellows on peach, E. M. HILDEBRAND (*Phytopathology*, 32 (1942), No. 8, pp. 712-719, figs. 2).—Cherry yellows was transmitted by budding and grafting from diseased to healthy sour cherries with the production of definite yellow-leaf symptoms within about a year, and similar incubation periods were obtained in transmissions from cherry to peach. Symptoms on the latter consisted mainly of a stunted rosette-type of growth. New indexing technics were developed which shorten the incubation periods to about a month. One method, which involved placing diseased cherry buds between two small rapidly growing shoots on cut-back peach grafts, induced early-stage symptoms within 2 weeks; another, which consisted of budding midway up the stem of large peach seedlings and cutting back to one node above the diseased bud, resulted in early-stage symptoms within a month; the third and most useful technic, which employed small 18-inch-tall seedlings, gave incubation periods of about 3 weeks when pruning followed immediately after budding. These rapid indexing technics are proving of great value in advancing the work on cherry yellows and should be applicable to other stone-fruit viruses.

Tomato ringspot on currant, E. M. HILDEBRAND. ([N. Y.] Cornell Expt. Sta.). (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 362-366, figs. 4).—A virus recovered in the juice extract from currant produced a disease on tobacco practically identical with tomato ring spot and considered a strain of this virus, since it agreed in all important particulars with the possible exception of being more virulent. Furthermore, cross-immunization tests with other ring spot viruses resulted in protection only against tomato ring spot, with which the host range, so far as tested, agrees. This is believed the first case of mechanical transmission of a virus from a woody plant to tobacco, and thus far it has not been possible to return the virus to currant by this means. Since the ring spot virus was obtained from some and not from other mosaicked currant plants, it is tentatively concluded that two entities are involved, viz, currant mosaic and tomato ring spot.

Notes on resistance and susceptibility of gladiolus varieties to the Fusarium yellows, L. McCulloch. (U. S. D. A.). (*Gladiolus* [New England Gladiolus Soc.], 1942, pp. 80-83).

More about control of black spot on roses, E. W. Lyle. (Tex. Expt. Sta.). (*Florists Exch. and Hort. Trade World*, 98 (1942), No. 21, p. 10, fig. 1).—Following a previously published digest⁴ of work on this disease by the Texas Experiment Station, the author here presents further data confirming the value of sulfur-copper dusts over sulfur alone in preventing infection. Best results were obtained from applications made within 24 hr. after each rain.

Bacterial blight of garden stocks and its control by hot-water seed treatment, J. B. Kendrick and K. F. Baker (*California Sta. Bul.* 665 (1942), pp. 23, figs. 6).—A bacterial blight of garden stocks in California has occurred for several years in cut-flower and commercial seed plantings and in home gardens. The disease attacks the main stem and lateral branches at all stages of plant growth, and its symptoms are described in detail. The principal damage has been a serious reduction in seed production during certain seasons, but many plants are also killed outright or badly stunted. The disease was readily reproduced by pure culture inoculations, and the pathogen, culturally and morphologically resembling *Phytomonas campestris*, is described and named *P. incanae* n. sp. The bacteria invade the vascular system and have been recovered from the stem, lateral branches, peduncles, and seed. Seed from infected plants when sown in steam-sterilized soil gave a small percentage of diseased progeny. Immersion of stock seed in water at 53°-55° C. for 10 min., followed by prompt cooling, resulted in complete control or greatly reduced the incidence of seedling infection in the greenhouse without material injury to the seed, and in field practice the occurrence of the disease was greatly reduced and seed production increased. Observations indicate that the pathogen persists in the soil, and thus a 2- or 3-yr. rotation is recommended. Drainage water from infested fields will spread the disease. Infested garden or greenhouse soil can be sterilized by steam or by soaking to a 6-in. depth with formaldehyde (1-50). There are 19 references.

The control of chlorosis in cottonwood trees and other plants, G. H. Starr (*Wyoming Sta. Bul.* 252 (1942), pp. 16, figs. 5).—Chlorosis, a common malady of different plants in various Rocky Mountain States, has been destructive to cottonwood and other trees in Laramie and elsewhere in Wyoming. The form most common in Laramie is apparently due to Fe deficiency, since it can be cured by direct treatment with Fe salts. The experiments reported indicate that placing ferric phosphate in holes in the tree is the most successful treatment yet found, and it is recommended. Of 113 trees treated in 1938 only 27 showed the need of another application by the end of the 1941 season. Other ferric salts have also been used successfully, especially ferric citrate. Ferrous salts have not given satisfactory results when injected, but a solution of ferrous sulfate (copperas) has corrected the chlorosis of herbaceous plants, shrubs, and small trees when applied as a spray.

Phloem necrosis: A virus disease of the American elm, R. U. Swingle (U. S. Dept. Agr. Cir. 640 (1942), pp. 8, figs. 4).—This disease caused an epidemic dying of American elms in the central and lower Ohio River watershed. It is identified by examining the inner bark of buttress roots or the lower trunk of phloem necrosis suspects for a yellow, yellowish-brown, or "butterscotch" discoloration and a faint odor of wintergreen. This discoloration is not usually found in branches and never occurs in the wood. Means of spontaneous spread under field conditions are not known, but the disease is readily transmitted by

⁴ Florists Exch. and Hort. Trade World, 98 (1942), No. 19, p. 11.

grafting. No cure is at present known, and no measure for the protection of healthy trees has yet proved effective.

Toxin formation by *Ceratostomella ulmi*, G. A. ZENTMYER. (Conn. [New Haven] Expt. Sta.). (*Science*, 95 (1942), No. 2472, pp. 512-513).—In this preliminary report on experiments begun in 1940, evidence is presented that *C. ulmi* produces a soluble toxic substance which is believed to be the primary factor in the pathogenesis of the Dutch elm disease, typical symptoms having been produced by injecting a sterile filtrate from cultures of the fungus. The significance of the finding and the chemotherapeutic possibilities are discussed.

A bluestaining fungus inhabiting the heartwood of certain species of conifers, C. M. CHRISTENSEN and F. H. KAUFERT. (Minn. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 8, pp. 735-737, fig. 1).—A bluestaining fungus was isolated from the heartwood of each of more than 50 white cedars (*Thuja occidentalis*) in Minnesota. No spores were formed, but it propagated readily by hyphal fragmentation. Inoculated with this fungus, sterilized pieces of heartwood developed the typical dark blue stain. The pathogen grew through all the wood elements much as do some wood-rotting fungi. One or more other fungi were closely associated with the stain fungus in the wood and have been recovered invariably with the latter in isolations on agar media.

The biology of *Fomes fomentarius*, M. T. HILBORN (*Maine Sta. Bul.* 409 (1942), pp. [3]+161-214, pls. 17, figs. 4).—The author's general observations indicate that *F. fomentarius* is among the most important decay-producing fungi attacking hardwoods, which make up much of the 15,000,000 acres of Maine forests, and that it attacks birch more frequently than most other trees. About 27 binomials have from time to time been applied to the fungus, which has been reported from most parts of North America and from the British Isles, Europe, China, Japan, and Africa on 23 genera and 53 species of trees. In New England it is practically restricted to species of birch and beech. The morphology of the sporophore was studied in detail, and the spore-discharge period was found to cover about 180 days and to be influenced by humidity, temperature, and food reserves present. A considerable variation in the time-growth curve in culture was noted for various isolates on the same medium and for cultures of the same isolate on different media, but the group of 28 isolates from North America and Europe studied gave no indication of the existence of strains or local races within the species. No significant differences were observed in the reaction of the isolates to temperature, acidity, or the ability to produce the oxidase reaction on gallic- or tannic-acid media. All isolates exhibited mutual aversion when any two were plated together.

The fungus destroyed heartwood and sapwood at equal rates in cultures, but different isolates varied in the rapidity with which they destroyed wood from the same source and in their saprogenicity according to the tree species. Field studies showed that the parasite causes a typical white mottled rot in the heartwood and sapwood of living and dead trees, apparently attacking both parts simultaneously in dead trees but the heartwood first in living trees. Cell walls were found to be penetrated in various ways, and the secondary cell wall is probably invaded following the ramification of the hyphae through the wood parenchyma and wood ray cells. Lignin and cellulose are attacked simultaneously, and no differences were found in the utilization of pentosans. The decrease in alkali solubility characteristic of the white rots was also noted here. Losses in calorific value of decayed wood were proportional to the reductions in dry weight. There are 88 references.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Interrelations of rodents and other wildlife of the range, E. E. HOEN and H. S. FITCH (*California Sta. Bul. 663 (1942), pp. 96-120, figs. 3*).—The subject is dealt with under the headings of wildlife and its interrelations, rodents and rabbits of the range, factors influencing rodent and rabbit abundance, and effect of rodents on vegetation in the enclosures, the details being given in seven tables. The pounds per acre of forage remaining in the fall on comparable areas subjected to use by different kinds of animals in 1937-39 is summarized in a graph.

Control of moles, L. HASEMAN (*Missouri Sta. Cir. 233 (1942), pp. [4], figs. 2*).—A practical account.

Studies on valley quail, T. I. STOREY, F. P. CRONMILLER, E. E. HOEN, and B. GLADING (*California Sta. Bul. 663 (1942), pp. 130-135*).—Report is made of studies commenced in the autumn of 1936 by the Cooperative Quail Study Committee, organized to plan and direct work on the California valley quail (*Lophortyx californica vallicola*), the principal upland game bird of the Sierra Nevada foothills. The findings, which are summarized in tables, include censuses of valley quail on the range, principal types of cover used by quail for nesting, summary of nesting data for valley quail at the San Joaquin Experimental Range, and losses in nesting of valley quail. It is pointed out that, while final conclusions and definite management recommendations must be based on further studies, these statements of progress will illustrate the results thus far obtained.

Management of farm fish ponds, H. S. SWINGLE and E. V. SMITH (*Alabama Sta. Bul. 254 (1942), pp. [2]+23, figs. 15*).—The principles of pond management are first dealt with, followed by an extended discussion of the management of fish ponds, including proper stocking for new ponds, management of old ponds, fertilization of ponds, fishing, pond weeds and their control, and mosquito control.

[Insect investigations by the Idaho Station]. (Partly coop. U. S. D. A.). (*Idaho Sta. Bul. 244 (1942), pp. 36-39*).—Progress (E. S. R., 85, p. 786) notes by W. E. Shull, R. A. Fisher, H. C. Manis, E. L. Turner, M. C. Lane, F. H. Shirck, T. A. Brindley, and F. G. Hinman which mention dusts for legume bug control, control of *Empoasca flamentosa* DeLong obtained, alfalfa in rotation reduces wireworm population, and reduced per acre poundage of rotenone dust shows possibility in pea weevil control.

[Investigations in economic zoology and entomology by the Indiana Station]. (Partly coop. U. S. D. A., Ohio Expt. Sta., et al.). (*Indiana Sta. Rpt. 1941, pp. 60-67, figs. 2*).—A progress report (E. S. R., 86, p. 65) by G. A. Ficht, T. E. Henton, S. A. Anderson, R. H. Wileman, W. B. Cartwright, D. W. LaHue, C. Benton, P. Luginbill, H. R. Painter, E. V. Walter, G. E. Gould, G. E. Marshall, F. P. Zschelle, N. F. Childers, H. W. Brody, L. F. Steiner, J. E. Fahey, E. N. Woodbury, G. C. Oderkirk, and C. M. Kirkpatrick noting studies on the European corn borer, including work with lights and plowing under corn for control; cutworm research; hessian fly-resistant wheats; white grub control in turf; corn earworm and cucumber beetle studies; plant bug injury to tomatoes; control of gladiolus thrips; notes on the apple and grape leafhoppers; studies on the codling moth and oriental fruitworm; cockroach control; work of the Federal Fruit Insect Laboratory; organic chemicals as insecticides; rodent control; studies on rabbit repellents; groundhog or woodchuck control; and an ecological rat survey.

[Investigations in economic zoology and entomology by the Puerto Rico Station]. (Partly coop. U. S. D. A. et al.). (*Puerto Rico Sta. Rpt. 1940, pp. 36, 50, 65-85, figs. 6*).—A progress report (E. S. R., 84, p. 639), noting

scale insect control on bamboo by introduced insect predators; the fall armyworm; corn earworm, and corn-silk fly *Euxesta stigmatias* Loew as pests of sweet corn ears; effective methods for controlling corn ear pests; and, by K. A. Bartlett, introduction of five new species of beneficial insects; *Diatraea* borers for rearing parasites; introduction, liberation, and recovery of two strains of the Amazon fly *Metagonistylum minense* Tns.; shipments of *M. minense* to Louisiana and Barbados; liberations of *Theresia claripalpis*, a parasite of the sugarcane borer, at Guayama; shipment of *Coelophora inaequalis*, a predator of the yellow sugarcane aphid *Sipha flava* Forbes, to Louisiana; effective reduction of population of the coconut mealybug by the parasite *Pseudophycus utilis* Timb.; notable reduction in pineapple mealybug infestation in Lajas District through establishment of the parasite *Hambletonia pseudococcina* Comp.; a ladybeetle, *Egilus platycephalus* Muls., effective against the bamboo scales (*Asterolecanium bambusae* Bdv. and *A. miliaris* Bdv.); several scale predators (*Cladis nitidula* F., *Curinus* sp., and *Penttila castanea* Muls.) well established in various sections of the island; a coccinellid predator, *Ohilcorus cacti* L., proved useful for combating the white peach scale on papaya; receipt of shipment of the ladybeetle *Erochomus jourdanii* Muls., a new predator of bamboo scales, from Brazil; redistribution of bamboo scale predators to new localities; shipment of the adults of the bamboo scale predator, *Egilus platycephalus*, to Haiti; introduction of black scale parasites from California; shipment of negro scale, *Saissetia nigra* Niet., to California for rearing of parasites and predators; shipment of *Spalangia* sp. to Colombia to aid in control of the hornfly of cattle; and shipment of the giant toad *Bufo marinus* to Cuba. Biological studies and control of the bamboo powder-pot beetle *Dinoderus minutus* F. are noted by H. K. Plank.

Cotton insect problem met by research information as basis of poison program, C. LYLE (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 6, pp. 1, 5-6).—A practical account.

Daytime use poison dusts is effective, C. LYLE (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 5, pp. 1, 8).—A practical account.

Insecticides for victory gardens, N. P. LARSON (*South Dakota Sta. Cir.* 40 (1942), pp. 16).—A practical account.

Grasshopper control aided by tillage methods, J. A. MUNRO and H. S. TELFORD (*North Dakota Sta. Bul.* 309 (1942), pp. 14).—As a result of experiments conducted from 1939 to 1941 it was concluded that plowing or fall disking is useful in preventing subsequent grasshopper development. The relative effectiveness of different methods was as follows: (1) Moldboard plowing (fall) 96 percent, (2) one-way disk plowing (fall) 90, (3) double disking (fall) 86, (4) moldboard plowing (spring) 83, (5) duckfoot cultivation (fall) 73, (6) one-way disk plowing (spring) 69, (7) duckfoot cultivation (spring) 58, and (8) double disking (spring) 40 percent. Apparently the efficiency of plowing is the result of placing egg pods at lower soil levels where lower temperatures prevail during the incubation period, which results in delayed hatching and prevents subsequent emergence to surface. Double disking was probably correlated with the interval of time between the treatment and the beginning of the hatching period. Plowing for summer fallow is deemed valuable when begun from the outer margin of the field and so continued as to leave a narrow strip of vegetation for the concentration and subsequent poisoning of the grasshoppers. Cultivation just prior to egg-laying discourages oviposition in tilled areas. Temperature and direction of wind currents may be the main factors accounting for the varying efficiencies of tilled barriers for preventing the invasion of crops by grasshoppers.

The carrot weevil (*Listronotus latiusculus* (Behe)) in New Jersey and its control, B. R. PEPPER (*New Jersey Stat. Bul.* 693 (1942), pp. 20, figs. 7).—

The biology, habits, and control of the carrot weevil, a serious pest of celery, carrots, and parsley in certain sections of New Jersey, has been considered. Spraying and dusting with organic materials in celery fields gave poor control. Lead and calcium arsenate in sprays or dusts reduced injury 80 to 85 percent. Most effective control was obtained with a poison bait consisting of 95 lb. of dried apple pomace and 5 lb. of calcium arsenate broadcast at the rate of from 40 to 50 lb. per acre every 15 to 20 days.

Biological control of *Diatraea mauriciella* Wlk. in Mauritius.—I, **Investigations in Ceylon in 1939**, J. VINSON (*Bul. Ent. Res.*, 33 (1942), No. 1, pp. 39-65, figs. 7).—This is a report of an investigation in Ceylon from January to June 1939 of the moth borer *D. mauriciella*, a serious pest of sugarcane in Mauritius.

Crops or cutworms, G. F. KNOWLTON (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 2, p. 12).—A practical account.

Wireworm injury and potato varieties, H. S. TELFORD (*North Dakota Sta. Bmo. Bul.*, 4 (1942), No. 5, pp. 7-8).—During 1940 and 1941 the potato varieties Warba, Red Warba, Sebago, and Bliss Triumph were less heavily attacked than Pontiac, Cobbler, Mesaba, and Early Ohio. Apparently more wireworm injury occurs in the potato varieties which have fewer tubers per hill and which have their tubers growing in close proximity to one another.

Preparing bees for winter, R. S. FILMER (*New Jersey Stas. Cir.* 424 (1942), pp. 4).—A practical account.

Package bees, R. S. FILMER (*New Jersey Stas. Cir.* 426 (1942), pp. 4).—A practical account.

Lice and mites of livestock, H. E. BROWN (*Missouri Sta. Cir.* 231 (1942), pp. [4], fig. 1).—A practical account.

Ticks infesting domestic animals in Southern Rhodesia, R. W. JACK (*Rhodesia Agr. Jour.*, 39 (1942), Nos. 2, pp. 95-109, pl. 1; 3, pp. 202-218, figs. 2).—This is a revision of the contribution noted (*E. S. R.*, 81, p. 402), which includes (1) tables of diseases known to be transmitted by southern Africa ticks and (2) species of ticks recorded to date in Southern Rhodesia.

The keg shelter as a diurnal resting place of *Anopheles quadrimaculatus*, G. E. SMITH (*Amer. Jour. Trop. Med.*, 22 (1942), No. 3, pp. 257-269, figs. 5).—Investigations conducted have led to the conclusion that light traps and baited traps do not give an adequate measurement of the common malaria mosquito density. It was established that this species seeks a suitable diurnal shelter at dawn. An empty nail keg tends to provide such a shelter. These keg shelters when properly located near mosquito breeding places show promise as a means of defining anopheline densities in localized areas. They have the advantages of uniformity and mobility which are lacking in conventional collecting stations.

Subspecific variations among neotropical *Anopheles* mosquitoes and their importance in the transmission of malaria, L. E. ROZEBOOM (*Amer. Jour. Trop. Med.*, 22 (1942), No. 3, pp. 235-255, pls. 5).—This contribution is accompanied by a four-page list of references to the literature cited.

Studies on copper arsenite, a new anopheline larvicide, E. H. HINMAN, R. L. CROWELL, and H. S. HUELBUT (*Amer. Jour. Trop. Med.*, 22 (1942), No. 3, pp. 271-281).—Description is given of the laboratory technic of biological assay of arsenical dusts as anopheline larvicides. "From a preliminary survey of a wide variety of arsenites, copper arsenite and calcium arsenite were selected for more intensive study as larvicidal dust. . . . In the field it has been demonstrated that copper arsenite is at least the equivalent of paris green as a larvicide despite the fact that quantitative sampling indicated that only a small fraction actually reaches the water surface. Laboratory studies on the influence of particle size,

utilizing samples which have been fractionated by the use of the Federal air classifier, indicate that fractions which average 5μ or 15μ in diameter are more efficient larvicides than fractions averaging 25μ in diameter. Since the copper arsenite, as prepared in the pilot plant, has been of uniformly fine particle size, it is believed that its superiority over paris green may be in part attributed to this physical property. Studies on the influence of dilution of larvicides indicate that paris green or copper arsenite may be diluted with soapstone as much as 1:19 without reducing the larvicidal efficiency. Attempts to determine the minimum lethal dose of paris green for fourth instar larvae indicate that this is less than 0.0000004 gm. An entirely satisfactory determination of this has not been possible. Copper arsenite has exhibited a marked larvicidal superiority over paris green for first instar anopheline larvae."

Studies on the concentration and distribution of paris-green-lime mixtures applied as anopheline larvicides, R. S. HOWARD, JR., and J. ANDREWS (*Amer. Jour. Trop. Med.*, 22 (1942), No. 3, pp. 283-293, figs. 3).—Report is made of an investigation conducted with a view to improving local paris green larviciding practice by relating its limitations to certain measurable or preventable conditions. The authors' findings suggest that improvements in ground dusting and efficiency may be expected from the use of (1) a diluent whose density and behavior in aerial suspension is comparable to that of paris green or (2) pure paris green assuming that equipment could be developed to apply uniformly a pound or less per acre. Their experience shows that it is difficult to obtain regular dust coverage with less than 3 lb. of dust per acre with equipment now available.

ANIMAL PRODUCTION

[Investigations in livestock production by the Idaho Station] (*Idaho Sta. Bul.* 244 (1942), pp. 5-8, 9-10, 15-17, 51-58).—Results are briefly reported by W. M. Beeson, D. W. Bolin, C. W. Hickman, D. E. Brady, G. C. Holm, P. J. Carlson, J. W. Pence, C. E. Lampman, J. N. Thompson, L. R. Berg, R. F. Johnson, and E. F. Rinehart on the phosphorus requirements and blood phosphorus of sheep with and without cottonseed cake, alfalfa, and oats; lack of response of sterile rams to ascorbic acid therapy; swine progeny testing shows differences in dressing percentage; Michels' grass seed unsatisfactory for fattening hogs; calculi in sheep not caused by vitamin A deficiency; sardine oil a good vitamin D supplement for poultry; activated sterols as vitamin D supplements for poultry; dried whey as a flush mash for poultry and a source of riboflavin; liberal use of oats for feathering quality, egg production, mortality, etc., in poultry; sugar beet tops, molasses, and beet pulp for lamb and steer feeding; phosphorus in lamb rations and beef by-product rations for steers; and studies of potatoes, corn, and sorghum for silage.

[Livestock feeding and production studies by the Indiana Station] (*Indiana Sta. Rpt.* 1941, pp. 42-45, 46-48, 91, 92-96, fig. 1).—Results are briefly reported by C. M. Vestal, C. L. Shrewsbury, C. Harper, F. N. Andrews, F. G. King, L. P. Doyle, A. L. Delez, E. Barrick, R. King, N. E. Weitkamp, J. R. Wiley, C. W. Carrick, R. E. Roberts, S. M. Hauge, E. L. Johnson, T. E. Henton, and I. D. Mayer of studies on the effect of fish meal and fish oil on the flavor of pork; the effect of hominy feed on the quality of pork; deficiencies in rations responsible for death losses in fall beef calves; the chemical and physical changes of beef and pork during freezing and storage; the role of fat in swine nutrition and the quality of pork; comparison of open-pollinated and hybrid corn for growing and fattening hogs; protein mixtures of meat and bone scrap and other materials, especially soybeans, for growing and fattening brood sows; comparison of Atlas sorgo and corn silage for fattening cattle; nonleguminous roughages and protein

supplements with alfalfa hay for breeding ewes in winter; cause for losses and shrinkage of market hogs; types and grades of market hogs and breeding quality of products; soybean meal for laying hens and growing and breeding turkeys; substitution of soybean meal and corn for bran and middlings for growth of chicks; wheat and oats as substitutes for corn in broiler rations; influence of increased and reduced amounts of protein in the growing ration of chicks; effect of electric lights upon the growth of young chicks; effect of ultraviolet irradiation on growing chicks and laying pullets; ad libitum and restricted grain and mash feeding of laying hens; and effect of temperature and ventilation on egg production.

[Animal nutrition investigations] (*Fed. Proc. [Fed. Amer. Soc. Expt. Biol.]*, 1 (1942), No. 1, pt. 2, pp. 70, 87-88, 99, 100, 107, 108-109, 117-118, 134, 137, 189, 191-192).—Abstracts are given of the following papers presented on animal nutrition before the annual meetings of the American Physiological Society and American Society of Biological Chemists: Studies on Absorption From the Rumen, by A. D. Rankin (p. 70) (Cornell Univ.); The Thiamin Requirement of the Albino Rat as Related to the Carbohydrate, Protein, and Fat of the Diet, by W. W. Wainio (pp. 87-88) (Pa. State Col.); Relation of Protein and Purine Metabolism in Pigeons and Rats, by F. W. Barnes and R. Schoenheimer (p. 99); The Utilization of Amino Acids for Growth in the Mouse, by C. D. Bauer and C. P. Berg (p. 100); Induced Hypoproteinememia and Vitamin C Excretion, by C. A. Baumann, J. B. Field, R. S. Overman, and K. P. Link (p. 100); The Effect of Sulfapyridine on Nicotinic Acid Metabolism, by C. A. Elvehjem, L. J. Teply, and A. E. Axelrod (pp. 108-109), and Intestinal Synthesis of Biotin and Growth of Rats on a Low-biotin Diet, by G. M. Shull and E. Nielsen (p. 134) (all Univ. Wis.); Synthesis of Amino Acids by the Chick Embryo, by F. A. Osonka and H. W. Titus (p. 107) (U. S. D. A.); Vitamin E and Muscle Degeneration in the Hamster, by O. B. Houchin (pp. 117-118); Influence of Alpha-tocopherol and Unsaturated Fatty Acids Upon the Utilization of Vitamin A, by W. C. Sherman (p. 134), and Biological and Chemical Studies Related to Choline Deficiency, by R. W. Engel (p. 189) (both Ala. Polytech. Inst.); Thiamin and Riboflavin Metabolism, by B. Sure and Z. Ford, Jr. (p. 137) (Univ. Ark.); and Some Nutritional Requirements of the Hamster, by J. I. Routh and O. B. Houchin (pp. 191-192).

Experimental herd management, K. A. WAGNON, H. R. GUILBERT, and G. H. HAFT (*California Sta. Bul.* 663 (1942), pp. 50-82, pls. 2, figs. 5).—Data are reported on the gains and grazing of pregnant cows and their calves on the San Joaquin Experimental Range, with and without supplemental feeding mainly of cottonseed cake and rolled barley to one group during the dry season, in comparison with a group receiving no supplemental feeding except under emergency conditions. These two groups were started with 33 2-year-old helpers each in 1935 with age naturally advancing to 1940 and others added in 1938. In each group animals were grazed at the rate of 1 to 9 acres, 1 to 14, and 1 to 18 acres. Because of the division of numbers, differences in lots, and seasonal variations, definite conclusions as to the effects on cattle and ranges were not drawn. In general, with the supplemental feeding the total calf crop at weaning was usually greater. Animals that had not received supplemental feed made the best gains during the subsequent pasturing season, but the possibility of finishing and marketing 450-500-lb. weaner calves or 800-900-lb. yearling feeders through supplemental feeding was indicated. Gains under close grazing were definitely less than those from light and moderate grazing. Observations on the grazing habits, salt lick locations, and analyses of forage samples were included. Apparently about 50 percent more acreage appeared to be required to carry cattle from August to February than from February to August.

Grazing investigations on the northern Great Plains, J. T. SARVIS. (Coop. U. S. D. A.). (North Dakota Sta. Bul. 308 (1941), pp. 110, figs. 37).—Continuous grazing with steers at the rate of 3, 5, 7, and 10 acres of native pasture per head with other groups rotated showed over a 25-yr. period that the variations in seasonal rainfall and climatic conditions were rather uniform over this period. About 25 percent of the vegetation should remain ungrazed at the close of the season. The 100-acre pasture in which there were 10 2-year-old steers provided a greater area than necessary for 5 mo. grazing. The average daily gains on the 100-acre pasture from 1916 to 1935 were 2.10 lb., as contrasted with 2.08, 1.87, and 1.47 lb. per head daily on the 10-, 7-, 5-, and 3-acre pastures. The pasture grazed at the rate of 7 acres per steer gave practically the same results as 10 acres per steer with continuous grazing, and the vegetation was not seriously affected over the period of years. In another group grazed at the rate of 5 acres for 2-year-old steers the pasture was overgrazed, and some of the plants were driven out prior to the drought of 1934 and 1936. The pasture grazed at the rate of 3 acres per head was sufficient to carry the steers for an average of 109 days. Gains were severely reduced and the vegetation suffered from overgrazing. A 70-acre pasture was grazed by deferred and rotation methods at an average rate of 1 2-year-old steer on approximately 5 acres with gains intermediate between those in the 100- and 70-acre pastures of continuous grazing. The real value of a system of deferred and rotation grazing appeared to be its aid in restoring an overgrazed area, but the continuous grazing ordinarily practiced on the smaller area for a limited time was not advantageous. The most prevalent and palatable grazing plants on the area throughout the period were furnished by blue grama followed in order by western wheatgrass, nigger wool or thread leaf sedge, needle-and-thread, and other grasses based on ability to withstand grazing and gains produced by the cattle. Certain of the grasses proved most satisfactory during portions of the season but did not prove as suitable as others throughout the year. Yearling steers replaced 2-year-olds in 1936-40, and indicated that yearlings consume about 60-65 percent of the forage required by 2-year-olds. Various grasses were especially useful for small cultivated pastures for emergency grazing and for early spring grazing before native range is ready for grazing. The chemical composition and amount of the grasses available for clipping on the different plats are tabulated for several species.

Either Alyce clover or lespedeza hay is good maintenance ration for beef cattle, H. W. BENNETT and S. P. CROCKETT (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 5, p. 7*).—Beef cows and steers were satisfactorily wintered in different years with Alyceclover and lespedeza as the hay crops.

Comparison of shock corn, crib corn, and corn silage on an acre basis for finishing two-year-old cattle, M. JACOB and H. R. DUNOAN (Tennessee Sta. Bul. 178 (1942), pp. 23, figs. 6).—From the standpoint of gain, quality of beef, and financial returns produced per acre by different types of corn average results obtained in 3 yr. were decidedly superior for steers fed for 150 days on corn silage ad libitum with a medium ration of cottonseed meal. Lesser amounts of cottonseed meal with and without legume hay, shock corn, or ground ear corn in place of corn silage were not as profitable. The acre beef yields were 877.2 lb. with corn silage fed with 4.98 lb. of cottonseed meal per steer daily, 793.2 lb. with corn silage fed with more limited cottonseed meal and legume hay rations, 722.4 lb. with corn silage and limited cottonseed meal, 555.7 lb. with shock corn, cottonseed meal, and legume hay, and 380.3 lb. for steers on corn-cob-shuck meal, cottonseed meal, and legume hay rations. The stover and ear corn were ground.

Kudzu hay compared with standard ration for beef calves, yearling heifers, cows, A. E. CULLISON and J. L. HOLMES (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 6, pp. 2, 7*).—Although beef calves in a 2-week test and beef cows in a 63-day feeding experiment lost weight with kudzu hay when fed as a part of the ration, a lot of beef heifers were wintered successfully over a 90-day period with kudzu hay. The heifers did not seem to relish the hay, but they came through the winter in a healthy and vigorous condition and were no less thrifty than heifers wintered on Dallis grass hay, sorghum silage, and cottonseed meal. Kudzu proved difficult in feeding because of the coarse stems, but it may serve as a feed for wintering heifers and beef cows when other feeds are too expensive or not available. A feed rack was improvised for feeding it. Chemical analyses of kudzu stems and leaves are included.

Effect of exercise on quality of beef, S. BULL and H. P. RUSK (*Illinois Sta. Bul. 488 (1942), pp. 105-120, figs. 2*).—Exercise had no effect on the toughness of beef and caused no significant difference in flavor or other factors of palatability. Two experiments were conducted. In the first four steers each walked on the treadmill for 123 days an average of 3.7 miles per day. A like number of steers walked in the second experiment 132 days for an average of 3.9 miles per day. Each exercised steer was paired with a comparable one unexercised, and feed consumption was restricted to that of the unexercised animal. To produce 100 lb. of gain lightly exercised steers required an average of 17 percent more concentrates, 10 percent more silage, and 10 percent more alfalfa hay than unexercised animals. With heavy exercise there were required 72 percent more concentrates and 9 percent more hay, but 4 percent less silage than was required by unexercised animals per unit of gain. Exercise had no effect on the development of any of the organs or the dressing percentage although heavy exercise increased dressing percentage by reducing the fill. The quality of beef was not influenced, although there was indication that heavy exercise decreased resistance to shearing, thus confirming the reductions in collagen noted by Mitchell and Hamilton (*E. S. R., 69, p. 700*).

The influence of nutrition on the reproduction of ewes, H. M. BRIGGS, A. E. DARLOW, L. E. HAWKINS, O. S. WILLHAM, and E. R. HAUSER (*Oklahoma Sta. Bul. 255 (1942), pp. 30*).—Flushing or increasing the feed available to ewes just prior to and during the breeding season was not found beneficial in a 9-yr. study. Observations were made on 150 ewes as to the breeding behavior and reproduction when fed submaintenance, maintenance, and rations causing an increase in ewe weight prior to breeding. The numbers per lot in each test were small, and the variations occurring in the results made differences in the number of lambs produced and the time and occurrence of first oestrous ascertained by variance analyses nonsignificant. The heat periods of the ewes on the low levels of nutrition were, however, lengthened. The effect of breed and age on reproductive behavior of ewes was nonsignificant. It was noted that the fertility of rams was low in June, July, and August. The improved nutrition did not result in more lambs or an earlier lamb crop.

Control of leafy spurge by sheep, E. A. HELGESON and J. H. LONGWELL (*North Dakota Sta. Bimo. Bul., 4 (1942), No. 5, pp. 10-12, figs. 2*).—Further studies of sheep grazing leafy spurge in 1940 and 1941 were similar to the results reported for 1937 and 1938 (*E. S. R., 82 p. 234*).

A lamb feeding trial at the Williston Substation, J. H. LONGWELL and W. H. HUBER (*North Dakota Sta. Bimo. Bul., 4 (1942), No. 5, pp. 16-18*).—Results of a lamb-feeding trial from December 6, 1941 to February 28, 1942 showed a high value for alfalfa hay when fed with corn, barley, and oats as a grain mixture. The average daily gains produced were 0.3 lb. Crested wheat-

grass was not eaten as well as alfalfa but when linseed meal supplemented the grain mixture average daily gains of 0.3 lb. were made.

The feed requirements of market hogs—A tentative feeding standard, E. W. CRAMPTON and G. C. ASHTON (*Sci. Agr.*, 22 (1942), No. 6, pp. 390-400, figs. 3).—The individual feed consumption and weights of 480 pigs from birth to 200 lb. live weight were analyzed on the basis of 14-day periods for consideration of hog feeding standards. The data were fitted for each period to the regression equation $Y = k - b_1 - (W)^{-b_2} - b_3(G)$, wherein Y indicated the daily feed, $(W)^{-b_2}$ the actual or 0.73 power of the weight, and (G) the daily gain. Regression equations were calculated for 30-60, 70-100, and over 110 lb. live weight. These results showed that if anything the choice in weight which most closely approached the observed data was obtained with the first power of the weight rather than the 0.73 power. A hog feeding standard is proposed for feed requirements of pigs from weaning to 100 lb. and 100-200 lb. in which b_1 in the equation equals 0.04 and b_2 equals 1.0. The small negative k value found was ignored. For practical purposes satisfactory values could be obtained by simplifying the equation to $k=2$, $b_1=0.02$, and $b_2=1.0$ lb.

Chick vitality as affected by breeding, F. P. JEFFREY (*New Jersey Stat. Hints to Poultrymen*, 29 (1942), No. 4, pp. 4, fig. 1).—Differences in the chick mortality to 20 weeks of age were noted in different breeds and strains of poultry over a period of years.

Growth of Barred Rock chickens, J. E. PARKER and B. J. MCSADDEN (*Tennessee Sta. Bul.* 180 (1942), pp. 8, figs. 3).—The weights at 4-week intervals of one strain of Barred Rock chicks from 0 to 32 weeks of age are presented. These results showed that both sexes increased periodically up to 12 weeks. The largest gains were made by both sexes from 9 to 12 weeks. After this age there were decreases in the gains except from 21 to 24 weeks for pullets and 25 to 26 weeks for cockerels. The maximum weights of pullets occurred during February and March when the pullets were 48-52 weeks of age. The weights did not seem to be correlated with pullet mortality during the first year.

Dubbing production-bred Single-Comb White Leghorns, C. M. BICE (*Hawaii Sta. Cir.* 20 (1942), pp. 8, figs. 5).—General directions are presented for dubbing White Leghorn cockerels and pullets, with data to show that the operation did not have a deleterious effect upon body weight or sexual maturity of cockerels or egg production or egg size in pullets. Dubbing combs of δ s with large combs also increased vigor.

Battery management of chicks and layers in Hawaii, C. M. BICE and B. A. TOWER (*Hawaii Sta. Cir.* 19 (1942), pp. 23, figs. 20).—A general description of battery breeding and management of the laying flock under Hawaiian conditions, with directions for the feeding and management of battery chicks and construction of battery brooders.

Poultry feeding and confinement rearing experiments, H. B. HINDS (*Arizona Sta. Bul.* 184 (1942), pp. [2]+20, figs. 2).—The results of three tests with poultry are briefly reported.

I. *The comparative nutritive value of certain locally produced poultry rations.*—Three tests of 11 mo. duration each in which White Leghorn pullets were fed rations made up of scratch and mash of corn, barley, and red milo, in comparison with a check ration of corn, oats, and wheat products indicated that feed consumption, egg production, and mortality were not greatly different. Thus locally produced grains may be used in poultry rations provided proper protein supplements are added.

II. *Feeding tests.*—Four-yr. tests of 11 mo. duration showed that a 14 percent protein diet intermittently fed moist and dry was satisfactory for egg production

by Leghorn pullets. Groups receiving liquid milk with red milo, barley, and wheat made nearly as good production, but the production was lower on a ration changed at monthly intervals according to the cost of ingredients. Supplementing the check ration with dehydrated carrots did not prove worth while on account of the excessive cost of the carrots.

III. Confinement rearing.—Comparisons of different methods of management of young chicks to 18 weeks of age showed that those raised in an outside run with a concrete floor were larger and the plumage was superior to that of those raised on wire floors with a wire porch. A group raised on a concrete floor with a sun porch was nearly equal to a group with outside runs, but the latter had the lowest mortality. During the 3-yr. period 656 chicks were started by each method. In the rate of growth the order in the 3-yr. tests to 18 weeks of age from heaviest to the lightest was outside run, concrete porch, and wire floor. The birds raised on the wire floor had rough and ragged plumage and the heaviest mortality. In another comparison with lots of 150 chicks each better growth was made by chicks started in colony houses than by other groups held for the first 2, 4, or 6 weeks in batteries and later transferred to colony houses. There was difficulty in getting battery-started chicks to use the colony brooders.

The utilization of casein and amide nitrogen by chickens, V. G. HELLER and R. PENQUITE. (*Okla. Acad. Sci. Proc.*, 21 (1941), pp. 85-86, figs. 2).—Although casein furnished an excellent source of protein for chick rations urea was practically worthless because of the lack of bacterial synthesis. See also a note by Ackerson et al. (*E. S. R.*, 84, p. 94).

Cottonseed meal, shrimp meal, soybean meal, meat scraps, for growing chicks, C. E. BARNETT and H. D. POLK (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 6, p. 8).—In two comparisons of protein sources for growing chicks in lots of 50 crossbreds each it was found necessary to supplement a ration of about 17 percent meat scrap with manganese sulfate to avoid slipped tendon. A ration without milk but which contained protein from soybean meal, cottonseed meal, and alfalfa meal produced the cheapest gains. Good gains were made to 9 weeks of age with dried skim milk, shrimp meal, soybean meal, and meat scrap. The poorest weights were recorded for chicks receiving a 22-percent cottonseed meal ration.

Wartime feeding of poultry, G. P. GOODEARL (*North Dakota Sta. Bimo. Bul.*, 4 (1942), No. 5, pp. 13-15).—A general discussion of the nutritive requirements of chickens and turkeys and wartime sources of essential materials.

Carotenoids of grass silage, W. BOLTON and R. H. COMMON (*Nature [London]*, 148 (1941), No. 3752, p. 373).—The ready isolation of a blue-green chromogen from the petrol ether solution of the carotenoids of grassland silage was thought to have a possible relation to the grass yolks in the eggs of hens fed on silage or early young pasture.

Inactivation of vitamin B₁ by raw fish, E. H. SPITZER, A. I. COOMBS, C. A. ELVENJEM, and W. WISNICKY. (*Univ. Wis.*). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 376-379).—Data are presented which indicated that a typical B₁ avitaminosis can be produced in chicks by feeding 25 percent raw whole carp as experienced in fox feeding with a ration adequate in B₁. The occurrence of polyneuritis was prevented by cooking and water extraction of the carp or partially prevented by ether extraction or air drying. These conclusions were derived from feeding tests with 14 lots of 10 each of day-old chicks. Raw carp entrails seemed to be the most potent in the sources of destructive materials but cooking prevented the destruction of any of the thiamin. When the combination including 2.5 gm. of entrails and from 100 to 600 µg. of thiamin was used, destruction was prevented by cooking.

Biotin and scaly dermatosis of the chick, S. ANSBACHER and M. LANDY (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 3-5).—Biotin deficiency symptoms in the chick, as noted by Hegsted et al. (*E. S. R.*, 84, p. 803), were completely cured by the administration of crystalline biotin methyl ester and growth was stimulated, suggesting that the chick may be used for a quantitative biological assay of biotin.

Refrigerated brine sprays for cooling dressed poultry, M. H. SWEET and G. F. STEWART. (Iowa Expt. Sta.). (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 5, pp. 261-265, 308-313, figs. 3).—By the use of liquid sprays it was found possible to reduce the time necessary for air cooling 30-40 percent. In these studies groups of poultry and turkeys were cooled in air after treatment with brine sprays at 20°, 21°, and 22° F. These results are in accord with those previously noted by Williams et al. (*E. S. R.*, 87, p. 141).

A bile depletion method to eliminate liver stain in stored dressed poultry, W. A. MAW and N. NIKOLAICZUK (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 5, pp. 275-278).—The inclusion of 25 percent refined cottonseed oil in one or two preslaughter trough or individual feedings of broilers and roasters was effective in depleting the weights of the gall bladder and contents to such an extent that the extensive gall stain in storage was reduced materially. From a single feeding the gall bladder and contents weights of broilers was reduced over 50 percent. With one feeding the gall bladder and contents of roasters were reduced as much as 30 percent and about the same with feeding on the day of slaughter as well as the day before. The level of oil and the time interval between feeding and slaughter were important matters as regards the efficacy of the method. There were included in the study groups of 6-14 fowls each of different age and with different amounts varying from 10 to 33 percent of cottonseed meal in the ration. Some of the birds were stored up to 8 days at 32° F.

Egg storage: A selected bibliography, H. E. GORESLINE (*U. S. Dept. Agr., Bur. Agr. Chem. and Engin.*, 1941, pp. 14).—This bibliography consists of selected references covering the years 1890-1941, inclusive.

Turkeying-off sorghums and proso, W. O. WILSON and W. E. POLEY (*South Dakota Sta. Cir.* 38 (1942), pp. 7, figs. 4).—Three-yr. tests of turkeying-off Sooner milo, feterita, amber cane, and proso millet are presented using 95, 65, and 123 poults 9-10 weeks old per lot in the respective years. It would appear that birds harvesting their own grains use their feed about 80 percent as efficiently as controls receiving a ration of various grains and proteins which have given good results in other feeding experiments.

DAIRY FARMING—DAIRYING

[Dairy investigations in Idaho] (*Idaho Sta. Bul.* 244 (1942), pp. 11-14, 35).—Progress reports (*E. S. R.*, 85, p. 809) are presented for the following studies: The results attained through continuous use of proved sires in Holstein and Jersey herds over a period of 24 yr., methods of ensiling potatoes, and the relative efficiency of utilization of hay when fed once, twice, or three times daily to milking cows, by D. L. Fourt and F. C. Fountaine; stud bull associations as a means of providing the service of good dairy bulls for the small herd, by G. C. Anderson and Fourt; practices which have proved valuable in controlling mastitis, by Fourt, Fountaine, G. C. Holm, W. V. Halversen, and V. A. Cherrington; the danger involved in applying the Babcock test to cream containing sodium chloride and factors involved in the development of rancidity in Cheddar cheese, both by H. C. Hansen and R. S. Snyder; and factors responsible for the development of "wintry" flavor in butter, by Hansen and D. R. Theophilus.

[Investigations with dairy cattle and dairy products in Indiana] (*Indiana Sta. Rpt. 1941*, pp. 54-58).—Brief progress reports (E. S. R., 86, p. 80), by G. O. Mott, J. H. Hilton, J. W. Wilbur, R. J. Westfall, S. M. Hauge, P. R. Elliker, W. H. Brown, B. E. Horrall, W. F. Epple, J. C. Crane, V. C. Manhart, and K. C. Boxell, are presented for the following: Comparative returns secured from alfalfa-bromegrass v. bluegrass pastures for dairy cattle, the relative availability of carotene in rations for dairy cows, alfalfa-bromegrass silage v. corn silage for dairy cows, factors affecting mold growth in cream, the effect of storage conditions on the phosphatase reaction of butter, the value of soybean lecithoprotein as an emulsifier in ice cream, a study of the lecithin content of milk and its products, the character of Indiana butter from the standpoint of quality, the copper content of dairy products and its relation to the quality of the finished product, the relation between methods of separating cream from milk on the farm and the quality of cream marketed, and consumer preference for butter of different grades and characteristics.

Metabolism stalls, A. D. PRATT and C. W. HOLDAWAY. (Va. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 4, pp. 293-295, fig. 1).—The arrangement and construction of metabolism stalls for cattle are described and illustrated.

Grass silage in wartime, H. A. HERMAN and A. C. RAGSDALE (*Missouri Sta. Cir. 234* (1942), pp. 4, fig. 1).—Three practical methods are outlined for making grass silage without the use of molasses or mineral acids as preservatives, including (1) the use of ground corn, corn-and-cob meal, or other cereal grains, (2) the use of no preservative but allowing the crop to wilt so that the moisture content is about 65 percent, and (3) the use of dry or green sugary crops, such as sorgo, corn fodder, or other dried roughage.

Feeding grass silage, C. B. BENDER (*New Jersey Sta. Bul. 695* (1942), pp. 8, fig. 1).—Practical recommendations are offered for the feeding of grass silage, both to milking cows and growing heifers. Repeated feeding trials gave evidence that rations containing molasses-grass silage or phosphoric acid-grass silage are practically equal in production value to rations containing corn silage when compared on a nutrient basis. Milk produced on rations containing grass silage was superior in flavor, color, and resistance to oxidized flavor development in comparison with milk produced on corn silage or beet pulp.

Mungbean hay and mungbean silage for milk production, A. H. KUEHLMAN (*Oklahoma Sta. Cir. 101* (1942), pp. [4]).—In this brief résumé of feeding experiments with milking cows it is reported that in two trials an average of 133 lb. of mung bean hay was required to replace 100 lb. of No. 1 alfalfa hay. In three trials with silage 100 lb. of alfalfa hay was replaced by 268 lb. of mung bean silage on the average. Precautions to be observed in making satisfactory hay or silage from mung beans are discussed.

Sorghum silage economical for dairy herd, J. S. MOORE (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 6, pp. 1, 7).

Hay crop silage, N. N. ALLEN and J. B. FITCH (*Minnesota Sta. Bul. 360* (1942), pp. 16, figs. 8).—General recommendations for making and feeding hay-crop silage and certain advantages and disadvantages of ensiling such crops are presented. The results of experiments with alfalfa and sweetclover silages, including lots ensiled alone and with various supplements, indicate that even those of high moisture content without preservatives were generally well preserved. "As judged by general observations on color, odor, and taste, it is doubtful if any lot would have been consistently chosen as superior to others." Palatability tests showed all legume silages to be less palatable than corn silage. Among the legume silages, those containing molasses, phosphoric acid, or ground corn consistently ranked relatively high in palatability.

Minerals in dairy cattle nutrition: A review, G. BOHSTEDT. (Univ. Wis.). (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 441-458).—A concise review, citing 64 references to the literature.

Increased milk and milk fat production following the feeding of artificially formed thyroprotein (thyrolactin), E. P. REINEKE and C. W. TURNER. (Mo. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 393-400, fig. 1).—Following earlier experiments (E. S. R., 86, p. 822) on the growth response of goats to iodinated milk proteins (thyrolactin), this product was fed to lactating cows and goats. When fed from 5 to 10 gm. daily, the goats in declining stages of lactation showed an average increase in milk production of 10.51 percent. Concurrently the heart rate was accelerated an average of 8.2 beats per minute. In 14 individual trials cows receiving from 50 to 100 gm. daily responded with an average increase in milk yield of 8.59 percent. In 6 cases where milk fat analyses were made there was an average increase of 6.77 percent in fat percentage and 13.9 percent in fat yield. In discussing the practical possibilities of using iodinated proteins the need for following tested methods in their preparation is emphasized (E. S. R., 87, p. 267).

Vitamin A and carotene requirements for the maintenance of adequate blood plasma vitamin A in the dairy calf, P. D. BOYER, P. H. PHILLIPS, N. S. LUNDQUIST, C. W. JENSEN, and I. W. RUPEL. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 433-440).—Guernsey and Holstein calves were used in these trials, which extended from the thirtieth to the three hundred and seventieth day of age. Three levels of vitamin A intake, designated as deficient, border line, and adequate, were employed. The blood plasma vitamin A values proved to be a more delicate measure of the state of vitamin A nutrition than either growth or blood carotene. Blood plasma vitamin A values from 7 γ to 8 γ per 100 cc. were border line, with values below this definitely inadequate and values of 10 γ or more entirely adequate. Blood plasma carotene levels which would maintain an adequate blood vitamin A were from 50 γ to 70 γ per 100 cc. for Holsteins but from 110 γ to 140 γ per 100 cc. for Guernseys, thus indicating distinct breed differences. The daily intake of vitamin A which would maintain deficient, border-line, and adequate concentrations of blood plasma vitamin A were approximately 6 γ , 12 γ , and 18 γ per kilogram of body weight, respectively. Carotene intakes required to maintain an adequate plasma vitamin A were approximately 75 γ per kilogram for Holsteins and 125 γ per kilogram for Guernseys.

Parathyroid glands and lactation in the rat, S. J. FOLLEY (*Nature [London]*, 147 (1941), No. 3737, p. 744).—Confirming the results of earlier experiments,⁵ it was found that removal of the thyroid gland and the associated parathyroids from female rats at the sixth day of lactation markedly suppressed subsequent lactation, as evidenced by the limited growth and high mortality of the nursing young. Rats subjected to the same operation, but subsequently injected with liberal doses of Para-thor-mone (Lilly), were significantly better in lactational performance, leading to the conclusion that the integrity of the parathyroid glands is essential for normal lactation.

Arrangement of the tissues by which the cow's udder is suspended, W. W. SWEET, P. C. UNDERWOOD, C. A. MATTHEWS, and R. R. GRAVES. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 1, pp. 19-43, figs. 12).—The suspensory apparatus of the bovine udder was studied by embalming a cow in a standing position and dissecting away the various structures that serve to attach the udder in a suspended condition to the cow's body. Photographs show the appearance and arrangement of the tissues at each stage of dissection. An out-

⁵ *Jour. Physiol.*, 93 (1938), No. 4, pp. 401-412, figs. 4.

standing feature of the findings was the relatively small size and great tensile strength of the elastic sheets which form the median septum. This septum, which had a fanlike attachment to the udder surface, was capable of supporting the udder in a well-balanced position when all other supporting tissue was removed. The relatively small area of contact between the upper surface of the udder and the abdominal wall and the fact that much of the udder is located to the rear of the abdominal wall and does not follow its curvature emphasize the difficulty of accurately estimating udder-capacity in the living cow. Anatomical changes that may occur in an udder which has become pendulous or broken down are discussed.

The humoral nature of the factor causing the let down of milk, W. E. PETERSEN and T. M. LUDWICK. (Minn. Expt. Sta. et al.). (*Fed. Proc. [Fed. Amer. Soc. Expt. Biol.]*, 1 (1942), No. 1, pt. 2, pp. 66-67).—Following an earlier report that the oxytocic principle is active in the ejection of milk in the bovine (E. S. R., 85, p. 392), evidence was obtained through perfusion experiments with surviving mammary glands that the factor causing the let-down of milk is humoral in nature. Blood drawn from cows that had been stimulated to let down their milk was potent in this factor, whereas blood from cows that were not so stimulated had no effect. Blood from cows that were markedly excited did not cause a let-down of milk but had pronounced vasoconstricting properties causing a marked reduction in rate of blood flow. When blood was permitted to stand for $\frac{1}{2}$ hr. the humoral agent for the let down of milk was destroyed.

Effect of certain hormones and drugs on the perfused mammary gland, W. E. PETERSEN. (Minn. Expt. Sta. et al.). (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 2, pp. 298-300).—In further perfusion experiments the effect of nine different hormones and drugs upon the blood flow and ejection of milk in the perfused mammary glands was determined by injecting the substances into the arterial blood as it entered the gland. Only Pitocin and acetylcholine caused complete evacuation of the milk from the gland, while pitressin, epinephrin, histamine, and acetyl- β -methylcholine caused partial ejection of the milk. Epinephrin and histamine were powerful vasoconstrictors and when administered in sufficient quantity completely stopped the blood flow. Pitocin, pitressin, and ergonovine also caused some vasoconstriction. Carbamylcholine and atropine caused a slight increase in blood flow but had no effect on the ejection of milk.

Dairy goat management, G. VAN DER NOOT (*New Jersey Stas. Cir.* 418 (1942), pp. 16, figs. 9).—Principal topics of discussion in this popular publication are selection of a breeding herd; the breeding, feeding, and management of the goat herd; treatment of common ailments; characteristics of goat's milk; and methods for preparing hard cheese and cottage cheese from goat's milk.

Ascorbic acid in goat's milk, blood, and tissues, M. S. RICHMOND, C. D. GRINNELLS, and G. H. SATTERFIELD (*North Carolina Sta. Tech. Bul.* 68 (1942), pp. 39, figs. 3).—A more detailed report of research previously noted (E. S. R., 85, p. 234).

Effect of inhaled substances on milk flavors, W. E. PETERSEN and J. G. BERRINGTON. (Minn. Expt. Sta. et al.). (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 381-387).—Cows were forced to inhale for 2 hr. the odors from various substances tested, after which they were immediately removed to a separate barn and milked by machine. Samples of the complete milking were then judged independently by three judges for evidence of off-flavors. From the opinions of these judges it is concluded that inhalation of turpentine, paradichlorobenzene, camphor, or vanillin caused flavoring of the milk characteristic of

each of these compounds; inhalation of benzaldehyde, onions, and garlic caused a change in the flavor of the milk which was not characteristic of the compound; inhalation of odors from corn silage, alfalfa silage, and decomposing manure produced off-flavors in the milk; and inhalation of synthetic orchid or scrapings of Roquefort cheese produced no detectable off-flavors in milk.

Milk lipase and milk flavor, I. HLYNKA and E. G. HOOD (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 389-392).—A total of 144 milk samples representing 51 different cows were included in this study by the Department of Agriculture, Ottawa. Surface tension of the milk was employed as a measure of lipolytic activity, observations being made in the morning and afternoon following collection of the sample from the evening milking. A coefficient of correlation of 0.23 was found to exist between surface tension and flavor, indicating that lipolysis may be responsible for off-flavors in milk even though they are not definitely recognized as rancid flavors.

The phosphatase test—extent of use in North America, L. H. BURGWALD. (Ohio State Univ.). (*Jour. Dairy Sci.*, 25 (1942), No. 4, pp. 285-291).—Returns secured from a questionnaire mailed to 454 milk control laboratories, including city, State, provincial, county, private, and milk plant laboratories, showed that a high percentage of those reporting are now utilizing the phosphatase test as a measure of pasteurization efficiency. The Scharer field test was used most commonly, followed in order by the Gilcreas and Davis modification, a combination of the Scharer field and laboratory tests, the Scharer laboratory test, a combination of the Scharer field and Gilcreas and Davis tests, and the original Kay and Graham test. Data on official pasteurization time and temperature, modification of the various tests, number of samples tested by each method, and percentage of positive reactions are summarized.

Bacteria in creamery well water, C. JENSEN (*North Dakota Sta. Bimo. Bul.*, 4 (1942), No. 5, pp. 18-19).—A study of the water supplies of 42 creameries revealed that all except 4 contained types of micro-organisms capable of causing decomposition of milk fats and proteins. Defects in butter most commonly resulting from the introduction of such bacteria in the wash water were butyric, cheesy, oily, stale, and tallowy. The defects occurred rapidly at 70° F. but more slowly at 40°, and generally developed more slowly in salted than in unsalted butter.

The Babcock test: A review of the literature, E. O. HERREID. (Vt. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 4, pp. 335-370).—A comprehensive review, with 239 references to the literature.

The relationship of errors in the Babcock test to losses in cream plants, J. L. HILEMAN, K. K. RUSH, and C. MOSS (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 373-379).—Based on the testing of a large number of milk and cream samples, data are presented to show that the percentage of butterfat as measured by the Babcock test is consistently higher than that determined by the Mojonnier test. Because the error in fat content by the Babcock method was proportionately greater in milk than in cream, an apparent loss in butterfat resulted when this test was applied to milk and to the cream separated from it. This loss increased with increasing fat content of the milk skimmed, but decreased with increasing fat content of the cream produced.

The carotenoid content of milk fat fractions, V. N. KAUROVSKY. (Cornell Univ.). (*Jour. Dairy Sci.*, 25 (1942), No. 4, pp. 287-300, fig. 1).—Milk fat fractions obtained by fractional crystallization (E. S. R., 84, p. 666) were analyzed for carotene content (E. S. R., 82, p. 243). Carotenoid content was found to be inversely related to the melting points of the various fractions and directly related to their iodine numbers. The degree of oxidized flavor development in

the various fractions during the 2 years' storage at 4°–5° C. was inversely related to carotenoid content. It appeared that the antioxidative factors present in butterfat are concentrated in the liquid fraction. It is further suggested that the efficiency of absorption of carotene by an animal from its feed might be influenced by the degree of unsaturation of the fat content in the feed.

The curd number test: A method of testing the curdling qualities of milk, B. SPUR and I. J. WOLMAN (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 409–425, figs. 8).—The proposed test consists in artificially curdling milk under rigidly controlled conditions and then hardening the curds in formalin, followed by drying. The dried curd particles are then sieved through a battery of three screens of $\frac{1}{2}$ -, $\frac{1}{10}$ -, and $\frac{1}{100}$ -in. mesh, and the curd masses thus obtained are weighed. By applying an empirically derived formula of a so-called a–b–c type to this weight data, a curd number is obtained which epitomizes the milk's curdling qualities. Various factors affecting the accuracy of results are discussed at length. The curd number was found in general to run parallel to curd tension, although broader in scope and with greater applicability to research.

The bacteriology of brick cheese, II, III, E. M. FOSTER, J. C. GAREY, and W. C. FRAZIER. (Wis. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 4, pp. 313–321, 323–333).—Two additional reports are noted (E. S. R., 80, p. 826).

II. Comparison of washed-curd and conventional methods of manufacture.—Experimental lots of brick cheese were made by the conventional method except that the curd was subjected to varying intensities of washing between the cutting and dipping stage. A so-called mild wash consisting of adding 25 lb. of water per 100 lb. of milk, removing 50 lb. of whey, and replacing with 50 lb. of water was judged most effective. "After this treatment enough fermentable lactose remained in the curd to lower the pH to about 5.00–5.15 in cheese with a moisture content of 40–42 percent." Such washing had no appreciable effect on the rate of development of starter bacteria, although there was a slightly slower rate of acid formation in the washed-curd cheese. A starter containing a combination of *Streptococcus lactis* and *S. thermophilus* proved most desirable. When washing was applied to cheese from low-quality milk undesirable fermentation was more pronounced than in the conventional cheese, but when milk of good quality plus a mixed starter was used undesirable fermentations did not appear in the washed-curd cheese.

III. The bacteria involved in ripening.—Examination of 1,016 cultures isolated from brick cheese at different stages of ripening showed that *S. lactis* was a predominant organism throughout the ripening period when it was used as part or all of the starter. Its numbers increased to a maximum in the first few days and declined after 3 or 4 weeks. When *S. thermophilus* was used as the starter its numbers increased very rapidly during the first 12 hr., then decreased sharply after 1 or 2 weeks, and was seldom found in the later stages of ripening. Lactobacilli were common in raw milk cheese after 1 or 2 weeks, but were seldom present in cheese from pasteurized milk, *L. casei* occurring most frequently. A few cases of bitter flavor were attributed to excessive numbers of *S. liquefaciens*. *S. bovis* and *S. fecalis* were commonly present in cheese made from pasteurized milk. When pH of the cheese did not drop below 5.3 during the first 3 days of ripening, late gas formation by anaerobic spore formers generally occurred.

Preservation of cottage cheese, C. JENSEN (*North Dakota Sta. Bimo. Bul.*, 4 (1942), No. 5, pp. 19–20).—In an effort to develop methods for satisfactorily prolonging the storage period of cottage cheese, freshly made cottage cheese curds were held in brine solution varying from 0 to 5 percent salt for periods up to 14 days at 45° F. Those in 3- to 4-percent brine solution retained their fresh flavor and a desirable consistency over a 14-day period, while those in weaker brine solution or fresh water or in a dry state deteriorated quite rapidly.

The effect of high-temperature short-time forewarming of milk upon heat stability of its evaporated product, B. H. WEBB and R. W. BELL. (U. S. D. A.). (*Jour. Dairy Sci.*, 25 (1942), No. 4, pp. 301-311, figs. 4).—Control samples of milk forewarmed to 95° C. and experimental batches forewarmed over a range of temperatures from 101° to 165° C., with heating, holding, and cooling times of 4, 25, and 4 sec., respectively, were all evaporated to 26 percent total solids. A comparison of the evaporated milks indicated that while the relationship between high forewarming temperature and heat stability varied with different milks, stability was generally doubled and in some cases increased as much as six times that of the control milk. The optimum forewarming temperature for most milks fell between 120° and 140°. Milks forewarmed to produce excessively high stability were generally too thin, while those with too low stability were rough after sterilization. The use of optimum high forewarming temperature gave a greater increase in heat stability in the evaporated milk than could be attained through use of the optimum quantity of stabilizing salt to a normally forewarmed milk.

Curd strength of evaporated milk, J. C. MARQUARDT and D. W. DENNISTON. (N. Y. State Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 427-432, fig. 1).—Twenty-six samples of evaporated milk of known history representing individual plants in 22 different States were included in this study. The curd strength of the reconstituted evaporated milks ranged from 3 to 6 Hill units, which was markedly less than that of commercially homogenized milks and well within the standard for soft-curd milk adopted by the American Medical Association. When mixed with equal volumes of water, reconstituted evaporated milk did not lose its homogeneous properties when held at 4.5° C. for 18 hr.

The availability of the iron of cocoa and of iron-fortified cocoa mixtures, F. KINDER, W. S. MUELLER, and H. S. MITCHELL. (Mass. Expt. Sta.). (*Jour. Dairy Sci.*, 25 (1942), No. 5, pp. 401-408).—Results obtained in feeding trials with rats over a 6-week experimental period gave evidence that approximately two-thirds as much hemoglobin was regenerated from the iron of cocoa as from an equivalent amount supplied as ferric chloride. However, iron added to a cocoa mixture was completely available and the addition of 1.7 percent of pure tannic acid did not reduce the availability of iron added to a milk ration. Thus it appears that fortification of cocoa or chocolate milk with iron is warranted, since the factor which limited the availability of the iron of cocoa had no influence on added iron.

VETERINARY MEDICINE

[Work in animal pathology by the Idaho Station] (*Idaho Sta. Bul.* 244 (1942), pp. 10-11, 17, 29-31).—The work of the year (E. S. R., 85, p. 815) reported upon by G. C. Holm, W. M. Beeson, W. B. Ardrey, V. A. Cherrington, W. V. Hulverson, D. L. Fourt, and C. E. Lampman includes control of chronic swine erysipelas, swine brucellosis, prevention and control of bovine mastitis, pullorum disease in chicks, diagnoses of poultry diseases, and the reduction of poultry mortality by selective breeding.

[Work in animal pathology by the Indiana Station] (*Indiana Sta. Rpt.* 1941, pp. 92, 97-100).—The work of the year (E. S. R., 86, p. 87) reported upon by E. E. Schnetzler, S. E. Hartsel, J. F. Bullard, R. K. Waugh, J. H. Hilton, P. R. Elliker, B. E. Horrall, C. R. Donham, F. L. Walkey, L. P. Doyle, and A. L. Delez includes bactericidal agents of avian blood; the prevention and control of mastitis; potency and purity tests of anti-hog-cholera serum and virus and vaccines; diagnoses of animal diseases; fowl paralysis, leucosis, and neoplastic conditions;

Brucella abortus (strain 19) in mature cattle; brucellosis in bulls and in swine; abortion and sterility in herds free from Bang's disease reactors; and the hog cholera virus.

Percutaneous application of sulfanilamide in animals and men, B. ZONDEK, Y. M. BRONBERG, and B. SHAPIRO (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 1, pp. 116-120).—It is concluded that the percutaneous use of sulfanilamide may serve as an auxiliary method of chemotherapeutic treatment in certain cases.

The effect of sulfanilylguanidine on *Brucella abortus* in vitro, T. H. GRAINGER, E. V. GIBSON, and E. P. CAMPBELL (*Jour. Bact.*, 43 (1942), No. 2, pp. 265-266).—A study made of the effect of sulfanilylguanidine on an avirulent strain of *B. abortus* is reported upon. The plating materials used to test the mixtures of drug and bacteria were beef-heart infusion glycerol agar and nutrient broth. It was found that concentrations of the drug as low as 0.025 percent showed inhibition of growth. The stronger concentrations of the drug likewise exerted a marked effect upon the growth of the organisms.

Studies on the allergic and antigenic activity of sonic filtrate of *Brucella abortus*, E. L. STUBBS and I. LIVE (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 146-153).—A review of the literature with references is followed by the results of experiments conducted, presented in detail in tables. "Sonic filtrate of *B. abortus* produced skin reactions in sensitized rabbits and guinea pigs. The degree of reaction seemed to depend upon the protein concentration in the filtrate. An intravenous injection of live *B. abortus* into rabbits produced the best skin sensitivity to sonic filtrate. Animals injected with live culture intraperitoneally and those injected with heated but not killed organisms intravenously were less uniformly sensitized, while a phenol-killed culture injected intravenously did not produce an allergic skin sensitivity. The groups of rabbits which received, respectively, intravenous and intraperitoneal injections of live culture had the highest agglutinative titers, the group injected intravenously with heated culture ranked second, and the group injected with phenol-killed culture ranked third. Precipitins and opsonins were also present in the blood serums of the injected animals. Intracutaneous injections of single doses of sonic filtrate into control rabbits and guinea pigs did not sensitize these animals to subsequent skin tests after 4, 7, 10, and 24 weeks. However, the intracutaneous inoculations stimulated the production of agglutinins. The initial agglutinative titer and the length of time it persisted depended upon the concentration of filtrate used."

Response of sulfonamide-fast pneumococci to penicillin, H. M. POWELL and W. A. JAMIESON (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 387-389).—Comparative experiments conducted by the authors with penicillin and sulfapyridine in mouse infections with three types of pneumococci have shown penicillin to be an effective chemotherapeutic agent against both parent and sulfonamidefast pneumococci.

Effects of tyrothricin and actinomycin A upon bacteriophage and bacterial toxins and toxin-like substances, E. NETER (*Jour. Bact.*, 43 (1942), No. 1, pp. 10-11).

Vitamin A and its relationship to some of the commoner diseases of farm animals, N. S. BARON (*Vet. Rec.*, 54 (1942), No. 3, pp. 29-37).—Estimations were made of the vitamin A content of the livers of certain domestic animals, both in health and disease, the details being recorded for 105 sheep and lambs, 184 pigs, 16 cows, 29 calves, 32 fowl, and 3 foals, as well as 72 samples of ewes' milk. It was found that while the fetal lamb appears to store no vitamin A in its liver and to depend upon its mother's colostrum for its early supplies, the pig is born with a limited reserve. Evidence presented also suggests that the calf relies very largely upon colostrum for its initial supply of vitamin. Disease conditions in

which gastritis and enteritis are present and certain respiratory conditions (though not tuberculosis) appear to cause a lowering of the vitamin A reserve. In other diseases there seems to be little, if any, correlation between the vitamin A reserve and the disease process. The livers of tuberculous cows contained very much greater reserves of vitamin A than those of nonaffected animals. The details of the study are given in tables, and a list of 57 references to the literature is included.

Identification of selenium indicator species of *Astragalus* by germination tests. S. F. TRELEASE (*Science*, 95 (1942), No. 2478, pp. 656-657).

Some growth requirements of *Erysipelothrix* and *Listerella*. S. H. HUTNER and D. REGAN (*Jour. Bact.*, 43 (1942), No. 5, pp. 629-640, figs. 3).—Report is made of a study of the growth requirements of two strains of *E. rhusiopathiae* and one strain of *Listeria monocytogenes*, which led to the development for each of simple media allowing heavy growth. Growth of both organisms was measured by titration of acid production. Both *E. rhusiopathiae* and *L. monocytogenes* required one or more amino acids supplied as a casein or gelatin hydrolysate. All strains required riboflavin. *E. rhusiopathiae* required in addition oleic acid, which satisfied the serum requirement. The oleic acid was noninhibitory in the presence of adequate saponin. The occurrence and some of the properties of unidentified growth factors for both organisms are briefly described. Some applications of these findings are outlined.

Experimental transmission of St. Louis encephalitis virus by *Culex pipiens* Linnaeus. W. C. REEVES, W. M. HAMMON, and E. M. IZUMI. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 1, pp. 125-128).—That certain species of *Culex* mosquitoes may act as vectors of the virus of St. Louis encephalitis is supported by the following evidence: "(1) In certain areas *Culex* mosquitoes have fitted into the epidemiological picture to the extent that several workers have stressed their probable importance as vectors. (2) Virus is available to mosquitoes in the blood of doves and a number of other species of experimentally infected vertebrates. Evidence of naturally acquired infection has been demonstrated in the serum of many vertebrate hosts. (3) Infected *C. tarsalis* have been collected in nature. (4) *C. pipiens* has been shown to act as an experimental vector, transmission having been demonstrated to occur between the fourth and the eleventh day after an infective meal. Virus persists in the mosquito for at least 13 days."

Studies on Johnin. H. W. JOHNSON and B. F. COX. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 131-138).—Part 1 of this contribution (pp. 131-136), which deals with the comparative sensitivity of rabbits, guinea pigs, and chickens inoculated with *Mycobacterium paratuberculosis*, presents the results obtained from the use of mineral oil suspensions of this organism for sensitizing these animals, the details being given in six tables. Suspended in mineral oil, *M. paratuberculosis* failed to produce a satisfactory sensitization in rabbits when injected either subcutaneously or intraperitoneally; it failed to produce a uniform sensitization in guinea pigs when injected intraperitoneally. When suspended in mineral oil and injected subcutaneously in guinea pigs it produced a satisfactory initial sensitization only.

Part 2 (pp. 136-138) reports upon a proposed method of testing the potencies of Johnins, the details also being given in tables. It is proposed that the term "potency titer" be applied to the highest dilution at which a Johnin will elicit a satisfactory reaction in birds sensitized to this organism. An average reaction index of 1 was considered the minimum which indicated a satisfactory response. The system employed for the purpose of assigning potency titers to different lots of Johnin is set forth in tables. A positive (+) in any dilution of Johnin employed

indicates that the average reaction of the five birds tested with the dilution is one (1) or greater. A negative (—) in any dilution of Johnin indicates that the average reaction of the five birds tested with the dilution is nine-tenths or less.

Some observations on the pathology of pneumonia in the food-producing animals, R. F. LANGHAM, F. THORP, JR., R. T. INGLE, and L. B. SHOLL. (Mich. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 139-145, figs. 15).—A study of the pathology of 31 cases of broncho-pneumonia, including 9 bovine, 12 ovine, and 10 porcine, is reported. " β streptococci (Lancefield's group C) were isolated from 4 of the bovine lungs. In the ovine cases *Pasteurella ovis-septica* was isolated eight times. β streptococci three times, and Spray's diplococci four times. In the porcine cases *P. suilla* and β streptococci were each isolated four times. The gross pathology usually was confined to the apical and cardiac lobes, but it sometimes involved the diaphragmatic and intermediate lobes. The broncho-pneumonia appeared to begin as a bronchiolitis which soon spread to the adjacent alveoli, giving it a patchy appearance. The cellular exudate usually was dominated by polymorphonuclear leucocytes, but in 2 cases the dominant cells were mononuclear phagocytes. The interstitial tissues, pleura, and blood vessels occasionally showed various stages of inflammation. In the 13 subacute cases and 1 chronic case there was proliferation of fibroblasts and some fibrosis."

Two new *Salmonella* types with undescribed flagellar antigens, D. W. BEUNER and P. R. EDWARDS. (Ky. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 1, pp. 174-175).—The authors report upon two new *Salmonella* types with undescribed flagellar antigens, each type being represented by a single strain isolated from the feces of normal human carriers. *S. tennessee*, from the feces of a normal carrier who was employed as a food handler in a fraternity house, a number of the occupants of which were affected with food poisoning, was represented by the antigenic formula VI, VII: z_{29} . The antigens of *S. simsbury* were characterized as I, III, XIX: z_{27} .

Frequency of occurrence of *Salmonella* species, S. BORNSTEIN, I. SAPHRA, and L. STRAUSS (*Jour. Infect. Diseases*, 69 (1941), No. 1, pp. 59-64).—The types of *Salmonella* strains found among 280 examined during 20 mo. were: In man, *S. paratyphi* A, *S. paratyphi* B, *S. chester*, *S. derby*, *S. abortus equi*, *S. paratyphi* C, *S. choleraesuis*, *S. thompson*, *S. virchow*, *S. oranienburg*, *S. baccilly*, *S. montevideo*, *S. amersfoort*, *S. newport*, *S. bovis morbificans*, *S. typhi*, *S. panama*, *S. gize*, *S. anatum*, *S. poona*, and the recently described *S. wichita* and *S. havana*; in man and animals, *S. typhimurium*, *S. muenchen*, and *S. enteritidis*; in food-stuffs (dried eggs), *S. senftenberg*.

Sulfanilylguanidine in control of *Salmonella* infection and carrier state in mice, P. R. BEAMER (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 418-421).—The findings in this study indicate that *Salmonella* infection in laboratory colonies of mice may be effectively reduced if carriers are isolated and treated with chemotherapy. The treatment of infected animals with sulfanilylguanidine resulted in a decrease of *Salmonella* organisms in stool cultures. It is pointed out that in those few instances where chemotherapy is not effective the mice may be sacrificed in order to decrease the sources of infection.

Active immunity in mice against *Trichinella spiralis*, J. T. CULBERTSON (*Jour. Parasitol.*, 28 (1942), No. 3, pp. 197-202).—The findings reported have shown that mice become partially immune to *T. spiralis* as a result of either prior infection with the parasite or vaccination with its antigens.

Passive transfer of immunity to *Trichinella spiralis* in the rat, J. T. CULBERTSON (*Jour. Parasitol.*, 28 (1942), No. 3, pp. 203-206).

A preliminary report of the effect of X-ray on trichinosis in the rat, R. F. HONESS. (Wyo. Expt. Sta.). (*Jour. Colo.-Wyo. Acad. Sci.*, 2 (1940),

No. 6, p. 44).—In a group of infested rats X-rayed, 800 r. was found to cause a reduction of about 26 percent of the 150 trichina that had been fed to each rat. In the group fed X-rayed trichina, 800 r. was found to cause a reduction of nearly 85 percent.

Animal inoculations with pure cultures of *Trichomonas vaginalis* and *Trichomonas foetus*, R. E. TRUSSELL and S. H. McNUTT. (Iowa State Col.). (*Jour. Infect. Diseases*, 69 (1941), No. 1, pp. 18–28).—In the experimental work reported “vaginal inoculations of *T. vaginalis* in bacteria-free culture were successful only in *Macacus rhesus* monkeys. This same strain has been used to produce vaginitis in humans. *T. foetus* could be implanted in cattle and for very brief periods in dogs. Sheep, swine, horse, goats, guinea pigs, rabbits, and cats could not be infected vaginally with either trichomonad. Oral inoculations with *T. vaginalis* in chickens, turkeys, mice, and pigeons were unsuccessful. *T. foetus* could not be implanted by the oral route in chickens, turkeys, and pigeons. Rectal inoculations of chickens and turkeys with *T. vaginalis* were unsuccessful, and *T. foetus* could not be implanted rectally in turkeys. Subcutaneous inoculations of both organisms in guinea pigs were without effect. Intraperitoneal inoculations of turkeys, guinea pigs, and mice with *T. foetus* gave negative results, as did similar inoculations of *T. vaginalis* in turkeys and guinea pigs. Intravenous inoculations of cattle, dogs, and rabbits with both organisms were without apparent effect. Intracranial inoculations of calves, guinea pigs, and rabbits were equally negative. Both *T. vaginalis* and *T. foetus* were successfully cultured in chick embryos, although this was more difficult with *T. vaginalis*.”

Bovine tubercle bacilli in sputum, M. BEATTIE and R. NICKWONGER (Amer. Rev. Tuberc., 45 (1942), No. 5, pp. 586–588; Ital. abs., p. 588).—Of 366 strains of *Mycobacterium tuberculosis* that were isolated from the sputum of persons in hospitals and sanitariums in various counties in California and classified for type by growth on culture media, none was identified as the bovine type.

Latent feline tularemia apparently responsible for a human infection, E. JUNGHER. (Univ. Conn.). (*Jour. Bact.*, 43 (1942), No. 5, p. 643).

Spermatogenesis and oogenesis in *Haemonchus contortus*, a nematode worm parasitic in the fourth stomach of ruminant animals, W. L. THRELKELD and M. E. HENDERSON. (Va. A. and M. Col. et al.). (*Va. Acad. Sci. Proc.*, 1941, p. 172).

Bang's disease control, W. BINNS (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 2, pp. 9, 11, fig. 1).—The importance and means of eliminating Bang's disease from dairy herds are dealt with, and the Bang's disease vaccination program adopted in Utah is described.

Actinomycotic-like clubs associated with coccidioidal granuloma in cattle, J. TRAUM and O. W. SCHALM (6. Pacific Sci. Cong., Calif., 1939, Proc., vol. 5, pp. 873–876, figs. 4).—Observations which indicate that *Coccidioides immitis* may be included in the group of microbial agents capable of provoking club formation in granulomatous suppurating processes are presented.

Sporadic bovine encephalomyelitis, S. H. McNUTT (*North Amer. Vet.*, 23 (1942), No. 4, pp. 242–246).—A further account of the newly recognized disease of cattle first reported upon by the author in 1940 (E. S. R., 84, p. 528).

The diagnosis of Johne's disease of cattle by cultural methods, F. C. MINETT (*Jour. Pathol. and Bact.*, 54 (1942), No. 2, pp. 209–219).—This contribution refers to experiments on the reliability of methods which may be used for isolating the bacillus of Johne's disease from the intestinal mucosa or glands. The chief points dealt with are the preliminary treatment of infected material, the choice of culture medium, methods of seeding tubes, and the size and sealing of culture tubes.

Listerella infection in cattle, L. H. SCHWABE and H. E. BIESTER. (Iowa State Col.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 165-176, figs. 10).—Report is made of an investigation of a number of outbreaks of an infectious disease in cattle manifesting central nervous disturbances found to be caused by a small, motile, gram-positive organism belonging to the genus *Listeria*. Transmission experiments indicate that cattle are far more resistant to the disease than either sheep or swine. "The organism apparently loses its pathogenicity after repeated cultivation on artificial media. The virulence may be restored by serial passage through a series of laboratory animals. Infections of various degrees of intensity were reproduced under experimental condition. Fatal cases were obtained by intracranial inoculations in cattle. Intravenous inoculation in cattle resulted in a severe reaction of relatively short duration followed by complete recovery. Intracranial inoculation of the bovine strain proved fatal to the experimental swine. The intravenous inoculations produced less severe reactions followed by recovery. The disease transmitted to sheep by intracranial inoculation terminated fatally. The sheep inoculated intravenously experienced a severe reaction accompanied by a rise in temperature which was of short duration followed by complete recovery. Fatal infections were secured by intracranial inoculations in chickens. Intravenous inoculations in chickens produced no apparent reaction. The bovine strain of this organism is similar morphologically to that isolated from sheep and swine and possesses similar staining properties as well as cultural characteristics. Inoculation of animals with the cultures of the bovine strains produced agglutinins in the serums of most of them. These serums agglutinated antigens of both ovine and porcine strains. The reactions, however, were so variable and inconsistent that they can not be depended upon as a routine laboratory procedure."

The relation of leucemia and bovine lymphocytoma, W. W. THOMPSON and L. M. RODERICK. (Kans. State Col.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 159-165, figs. 6).—It is concluded that the term lymphocytoma is the most appropriate designation for the neoplastic process of animals primarily involving lymphoid cells and tissues. There is thought to be little justification for a more complicated nomenclature to supply a more descriptive terminology for variations in fundamentally the same malignant condition. Observations indicate, moreover, that lymphocytomatosis is probably the most common neoplasm of cattle, and that if adequate means of recognition are utilized it may be found to constitute a problem of economic significance. The neoplastic process is more or less regularly characterized by a varying degree of leucemia, while the differential white cell count quite constantly shows a large proportion of atypical lymphocytes in the circulating blood. Laboratory work indicates that a total white cell count and differential leucocytic count in cases of obscure bovine ailments usually will aid in diagnosing the condition. The pathology of the occasional cases of myelogenous leucemia is described.

Concise methods for the detection of streptococci of Lancefield's group B or C in milk samples, E. J. FOLEY (*Jour. Milk Technol.*, 5 (1942), No. 2, pp. 94-98).—Description is given of a laboratory method for the diagnosis of bovine mastitis caused by streptococci of Lancefield's group B or C by the use of Hotis tests and Edwards' broth modified by the addition of selective inhibitory agents. It is pointed out that the value of the tests described is emphasized by the recent finding of Minett (*E. S. R.*, 88, p. 247) that the study of incubated milk samples is the most suitable method of demonstrating *Streptococcus agalactiae*. The use of crystal violet to inhibit micrococci and of sodium azide to inhibit *Escherichia coli* greatly improves the Hotis test. The number of tubes suitable for prolonged incubation or further examination is increased. Typical

positive Hotis reactions develop in many positive samples. The significance of an acid cream line is enhanced as this change within 16 hours' incubation usually indicated streptococcus growth. The occurrence of growth of extraneous bacteria in broth transfers from incubated milk samples is reduced by the presence of 1/100,000 crystal violet in the modified Edwards' medium. By conducting several tests in practically one operation distinct advantages are obtained, and as there is a certain amount of overlapping in the efficiency of the diagnostic tests they tend to merge and confirm each other in the majority of instances. One need not rely alone on the reaction seen in the incubated milk sample since the nature of the streptococci can be quickly determined by serological methods. The results of one test complements the other.

Feeding as a contributory factor in the development of chronic mastitis, E. N. MOORE, H. O. HENDERSON, A. H. VAN LANDINGHAM, and C. E. WEAKLEY, JR. (W. Va. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 154-158).—Report is made of a study of 28 animals, conducted with a view to determining the effect of heavy corn feeding as a contributory factor in the development of mastitis, and with 16 animals to determine the effect of rate of feeding the grain ration. No appreciable difference was noted in the incidence or severity of mastitis between the experimental and control lots. Physical, biologic, and chemical tests demonstrated wide variation in the severity of mastitis among individuals, but not between the two groups. Thus it appears that no appreciable increase in the incidence or severity of mastitis occurred as a result of the kind of ration or the rate of grain feeding under the conditions of these experiments.

The role of disinfectants in the control of mastitis, C. S. BRYAN, C. W. DARBY, W. L. MALLMAN, and A. C. CORBETT. (Mich. Expt. Sta.). (*Jour. Milk Technol.*, 5 (1942), No. 2, pp. 77-85).—In the experiments conducted, the details of which are given in nine tables, soap solutions were found to be unsatisfactory germicidal agents inasmuch as many strains of streptococci, *Staphylococcus aureus*, and *Escherichia coli* were unaffected. Sulfonated alcohols exhibited germicidal properties comparable to soaps. Soaps and sulfonated alcohols are unsatisfactory agents for destroying the organism on the udder causing mastitis. Hypochlorite solutions containing 1 p. p. m. available chlorine killed α , β , and γ streptococci in less than 1 min. A fresh hypochlorite solution containing 200 p. p. m. available chlorine is recommended for the disinfection of cows' udders. Hypochlorite solutions, turbid from the introduction of organic matter, are unreliable disinfectants.

Bovine tuberculosis: Its incidence in bone, joint, and cervical lymph node lesions in Italy, P. F. DE GARA (*Amer. Rev. Tuberc.*, 45 (1942), No. 5, pp. 576-585; *Ital. abn.*, p. 583).—In the examination of 195 cases of extrapulmonary tuberculosis in northern Italy from 1934 to 1939, the bovine type of tubercle bacilli was found in 9.2 percent. Of these cases, 174 had tuberculous bone and joint lesions, 13 of which were caused by bacilli of the bovine type. The remaining 21 cases had cervical lymph node lesions; 5 of these were due to the bovine type. Bovine tuberculosis was observed in 40 percent of the children below 5 yr. of age, in 16.6 percent of those between the ages of 5 and 15 yr., and in 6.4 percent of the persons older than 15 yr. The importance of infected raw milk or of prolonged contact with infected cattle in the etiology of infection with bovine tubercle bacilli is discussed. The contribution is presented with a list of 46 references to the literature.

A study of Actinobacillus lignieresii from sheep affected with actinobacillosis, H. A. TURNICLIFF. (Mont. Expt. Sta. et al.). (*Jour. Infect. Diseases*, 69 (1941), No. 1, pp. 52-58).—In two outbreaks of actinobacillosis of sheep in Montana *A. lignieresii* was recovered. A bacteriological study made with

these strains included their biochemical properties, fermentation reactions, and antigenic relationship, and comparisons were made with cultures of *A. lignieresii* of bovine origin. *Bacterium purifaciens* (Christiansen) seems to correspond in all essential details to *A. lignieresii*, and in all probability they are the same organism.

The development of cobalt deficiency in sheep, J. E. BOWSTEAD, J. P. SACKVILLE, and R. D. SINCLAIR (*Sci. Agr.*, 22 (1942), No. 5, pp. 314-325, figs. 3).—The feeding tests here reported supplement earlier work (E. S. R., 82, p. 233).

Helminth parasites of sheep, W. L. THRELKELD. (Va. A. and M. Col.). (*Va. Acad. Sci. Proc.*, 1941, pp. 172-173).—A contribution based upon work noted (E. S. R., 85, p. 669).

John's disease of sheep, D. F. EVELETH, R. GIFFORD, and C. H. ANTHONY. (Ark. Expt. Sta.). (*Vet. Med.*, 37 (1942), No. 6, pp. 241-247, figs. 10).—In work in Arkansas a high percentage of sheep have reacted to the intradermic Johnin test. The authors have found it possible to demonstrate acidfast organisms in the intestinal mucosa of 15 of 24 reacting sheep. It is sometimes possible to demonstrate acidfast organisms in the intestinal mucosa of sheep that fail to react to Johnin. The interrelationship between the symptoms of ovine John's disease and parasitism is discussed and the possibility of interspecies transmission of John's disease considered. Preliminary studies have indicated that the usual symptoms of John's disease rarely if ever develop in the pig. Numerous "reactor" swine have been examined post mortem, and acidfast organisms have been demonstrated in the intestinal mucosa. The animals examined have never presented evidence of avian tuberculosis. At the present time the authors are inclined to regard John's disease-infected swine as possible dangerous carriers of the disease.

Stomach worm (*Haemonchus contortus*) infection in lambs and its relation to gastric hemorrhage and general pathology, J. S. ANDREWS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 1, pp. 1-18, pl. 1, figs. 8).—A study of *H. contortus* infection in 19 crossbred Hampshire-Southdown lambs from 2 to 8 mo. old, conducted at the Beltsville Research Center in 1933 and from 1936 to 1938, inclusive, is reported upon. In the course of this work from 2,000 to 181,000 infective larvae of *H. contortus* were administered to lambs in single and multiple doses. Although one dose of 35,000 larvae undoubtedly would have produced death in 1 lamb had this animal been allowed to die naturally, much larger total doses were not fatal when administered in small daily doses. This observation indicates the development of resistance to infection in the lambs receiving the multiple doses. The data show that *H. contortus* produced a severe and sometimes fatal anemia in sheep. Blood appeared in the feces from 6 to 10 days after infection. In the two cases which were fatal, blood was present in the feces until the death of the animals. In lambs recovering from the infection the anemia was negatively correlated with the number of worm eggs per gram of feces. In lambs dying before the worms matured anemia developed rapidly, but a positive diagnosis of the infection was impossible before autopsy owing to the absence of worm eggs in the feces. In two of the fatal cases no worm eggs were passed in the feces, whereas one of the nonfatal cases had an egg count of 24,800 eggs per gram of feces. Accordingly, there was no correlation between the number of eggs per gram of feces and the fatality of the infection.

The quantities of blood lost during a period of 10 days in 2 of the lambs that died were 1,492 and 2,380 cc., or 1.57 and 2.50 times, respectively, the original quantity of blood in the lambs, as calculated from the body weight of the animals. These quantities compared favorably with the 3,560 cc. of blood taken from the jugular vein of a healthy lamb over a period of 15 days, until approximately the

same degree of anemia had been produced. This volume of blood was about 2.5 times the original volume of blood in this lamb, as calculated from its body weight. That the anemia associated with *H. contortus* infection in sheep was due to gastric hemorrhage alone was further indicated by the normal icteric index, the presence of reticulocytes in the blood of the anemic lambs, and the gross pathology and histological findings.

Internal parasites of sheep, C. ELDER (*Missouri Sta. Bul.* 447 (1942), pp. 8, figs. 2).—A practical summary of information.

Neutralizing antibodies in the cerebrospinal fluid in relation to cerebral resistance to equine encephalomyelitis virus, I. M. MORGAN, R. W. SCHLESINGER, and P. K. OLITSKY (*Jour. Bact.*, 43 (1942), No. 1, pp. 83-84).

A large-scale serum-neutralization survey of certain vertebrates as part of an epidemiological study of encephalitis of the western equine and St. Louis types, W. M. HAMMON, H. W. LUNDY, J. A. GRAY, F. C. EVANS, F. BANG, and E. M. IZUMI. (Univ. Calif., Wash. State Col., U. S. D. A., et al.). (*Jour. Immunol.*, 43 (1942), No. 5, pp. 75-86).—Further investigations in the Yakima Valley, Wash., during the spring of 1941 (E. S. R., 86, pp. 385, 386; 87, p. 117) are reported. "From an irrigated western valley region, where both St. Louis and western equine encephalitis occur in annual epidemics, 576 sera representing 74 species were examined by means of the neutralization test for antibody against both viruses. Each of the viruses was neutralized by approximately 50 percent of the sera from domestic fowl and to a less extent by sera from domestic mammals. The sera from wild species from each group showed a significantly lower percentage of positives than those from the respective domestic groups. Only 8 percent of the sera from wild mammals possessed antibodies. No sampling error was found which would alter the significance of these differences. From 'control' areas, where encephalitis was not recognized, 132 sera, largely from domestic species, were tested. Only 1 was positive. This confirms the specificity of the neutralization test. In this valley the epidemiology of these two diseases appears to be parallel. It is concluded that many of these birds and mammals, principally the domestic fowl, probably serve as reservoirs for infection of mosquitoes. The percentage of susceptible horses which become infected is very high."

The findings suggest that in a region where encephalomyelitis has occurred previously a large percentage of the horses which have not been clinically ill have nevertheless been infected and have developed antibodies. The percentage of "immune" horses in Yakima approached 100 percent. This indicates that for some reason infection rates are higher among horses than other animals, and that when a new epizootic occurs the number of susceptibles is very limited, in fact limited almost entirely to a few of the 1- and 2-year-olds. It is readily understandable, therefore, that with a high infection rate among susceptibles and a few susceptibles available to start with that the horse epizootic burns out comparatively early in the season. In view of this fact, it is not necessary to postulate a separate vector for the horse, but that the one or principal vector bites horses very frequently. The present data on the feeding habits of *Culex tarsalis* are considered to be entirely compatible with this hypothesis (E. S. R., 86, p. 386).

A list is given of 24 references to the literature cited.

Infection of horses with St. Louis encephalitis virus, experimental and natural, W. M. HAMMON, B. N. CABLE, and E. M. IZUMI. (Univ. Calif.). (*Soc. Nupt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 335-340).—In continuation of these studies (see above) it is shown that horses from many of the Western States and from Massachusetts have antibodies, in varying proportion, to the

St. Louis encephalitis virus. Inoculation in nonimmune horses by the subcutaneous, intranasal, or intracerebral routes of a St. Louis virus freshly isolated from mosquitoes failed to produce clinical disease. It did produce inapparent infection resulting in the presence of virus in the blood in two instances in which suitable tests were made, and in all four inoculated animals induced a high titer of serum antibody. It is concluded that in horses inapparent infection occurs frequently in many widely scattered areas of the United States.

Notes on susceptibility of the golden hamster (*Cricetus auratus*) to equine encephalomyelitis virus, M. S. SHAHAN and G. T. CREECH. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 193-194).—Experiments reported have shown the golden hamster to be susceptible to both western and eastern equine encephalomyelitis virus injected intracerebrally or subcutaneously. The pathology of the disease in hamsters corresponds to that found in guinea pigs.

Transmission of equine infectious anemia by the stablefly (*Stomoxys calcitrans*), the horsefly *Tabanus sulcifrons* (Macquart), and by injection of minute amounts of virus, C. D. STEIN, J. C. LOTZE, and L. O. MOTT. (U. S. D. A.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 183-193, figs. 8).—Following a review of the literature on the transmission of infectious anemia by arthropods, report is made of experimental work which indicates that infection in a susceptible horse can be induced by the subcutaneous inoculation of 1 cc. of virus in 1:1,000 dilution, or by repeated pricking of the skin with a hypodermic needle contaminated with virus. It is pointed out that the findings on fly transmission of infectious anemia here reported confirm the earlier work by Scott (*E. S. R.*, 48, p. 283) and support the contention that blood-sucking flies probably play an important role in the dissemination of infectious anemia. Three positive cases of fly transmission are reported. Two susceptible horses developed infectious anemia 10 to 11 days after having been bitten by *T. sulcifrons* and one susceptible horse 24 days after being bitten by the stablefly. Conclusive evidence also was obtained that the mouth parts of horseflies subsequent to feeding on an infected horse contained virulent virus.

Neutralization studies of the viruses of influenza A, influenza B, and swine influenza with equine influenza convalescent serums, T. O. JONES and F. D. MAURER (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 179-182).—In studies of serums from horses convalescent from equine influenza, detailed in three tables, no significant increase in neutralizing capacity against the WS, Melbourne, and PR-8 strains of influenza A, swine-influenza virus, or the TM strain of influenza B virus was detected.

Occurrence in the horse of two parasites of cattle, *Ostertagia ostertagi* (Stiles, 1892) and *Cooperia oncophora* (Railliet, 1898), H. ROTH and N. O. CHRISTENSEN (*Jour. Parasitol.*, 28 (1942), No. 3, p. 245).—These unusual parasites, normally inhabiting the alimentary tract of ruminants, are reported as having been met with three times in the horse when a large number of horse stomachs and duodenum were examined.

Epithelial tumors of horses, R. A. RUNNELLS and E. A. BENBROOK. (Iowa State Col.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 176-179, fig. 1).—Of the 73 epithelial tumors of horses which form the basis of the report here presented, 7 were papillomas, 54 squamous-cell carcinomas, 2 adenomas, and 10 adenocarcinomas.

Some effects of cobalt and liver substance on blood building in dogs, D. V. FROST, E. H. SPITZER, C. A. ELVEHJEM and E. B. HART. (Wis. Expt. Sta.). (*Amer. Jour. Physiol.*, 134 (1941), No. 4, pp. 746-754, fig. 1).—The authors observed an inhibition of the normal hematopoietic response to iron and copper

feeding in dogs made anemic by hemorrhage and fed cobalt prior to the addition of iron and copper. Hematopoietic activity was resumed on the feeding of whole dry liver or liver extract. The compounds in liver which caused this profound hematopoietic response have not been determined. A temporary polycythemia was produced in adult dogs by feeding from 3 to 6 mg. of cobalt per kilogram of body weight in addition to the usual mineralized milk diets. High levels of cobalt had a toxic effect on young growing dogs and little apparent effect on the blood picture.

A note on the probability of error in the diagnosis of rabies by microscopic search for Negri bodies, S. R. DAMON and T. F. SELLERS (*Vet. Med.*, 37 (1942), No. 6, pp. 253-255).

Encephalitis (?) in red fox in southwestern Ohio, H. BEZDEK (*Jour. Mammal.*, 23 (1942), No. 1, p. 98).—Brief reference is made to a native red fox in Ohio apparently afflicted with encephalitis, examination of the brain for rabies having proved negative.

The role of coccidia as parasites of wild life, J. W. SCOTT. (Univ. Wyo.). (*Jour. Colo.-Wyo. Acad. Sci.*, 2 (1940), No. 6, p. 45).—This is an abstract of a contribution in which previous work relating to coccidiosis in wildlife is reviewed and information pertaining to coccidiosis among sage grouse in Wyoming is considered. Serious outbreaks of this affection occurred in Wyoming in 1933 and 1939, with the heaviest losses, estimated at 15 to 25 percent, among young birds which began to die about the middle of July. See also a contribution by Honess on coccidia infesting the bighorn sheep in the State (*E. S. R.*, 87, p. 273).

Observations on a fungus skin disease of Iowa muskrats, P. L. ERRINGTON. (Iowa Expt. Sta. et al.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 195-201).—It was found during the summers of 1935, 1936, and 1938 that 9.6 percent of 364 litters of muskrats handled on or in the vicinity of Round Lake, a northwest Iowa marsh, suffered from skin disease due chiefly to *Trichophyton mentagrophytes*. Evidence from other localities, where less intensive studies of young animals were carried on between 1934 and 1940, suggests that the disease may be widespread, at least within the boundaries of the State. Only young muskrats less than 2 mo. old appeared visibly affected, infections being invariably fatal to those showing gross manifestations before the age of 2 weeks. Ninety-eight of 134 members of infected litters were recorded as contracting the ailment, and of the 98 individuals, 90 appear to have died. In general, incidence and severity of infection alike rose as the breeding season (mid-April to late August) of the muskrats progressed.

Causes of death of chickens: A review of a California study, H. L. WALTER (*North Dakota Sta. Bimo. Bul.*, 4 (1942), No. 5, pp. 8-9).—This is a review of the work by Hoffman and Stover in California previously noted (*E. S. R.*, 87, p. 571). The most frequent causes of death (3 percent or more) for birds of all ages were coccidiosis 23.3 percent, colds and coryza 7.7, intestinal roundworms 6.0, paralysis 5.6, enteritis 5.3, pullorum disease 5.2, tumors 3.6, and ulceration (gizzard) 3.2 percent. The birds were classified in six age groups, the frequency determined by age groups being as follows: 4 weeks and under, 5 to 12 weeks, 3 to 6 mo., 7 to 12 mo., 1 to 2 yr., and 2 yr. and over. The study revealed that 64.4 percent of the causes of death were of birds less than 7 mo. old.

Diseases of brooder chicks, C. D. LEE. (Iowa State Col.). (*North Amer. Vet.*, 23 (1942), No. 4, pp. 259-264).

The effect of phenothiazine on the hemoglobin concentration of chickens, E. C. McCULLOCH and L. G. NICHOLSON. (Wash. Expt. Sta.). (*Vet. Med.*,

37 (1942), No. 6, pp. 248-252, fig. 1).—The work reported, details of which are given in three tables, indicates that the administration to chickens of the therapeutic dose of phenothiazine and 2, 5, and 10 times this amount does not significantly lower the hemoglobin concentration of the blood.

Preparation of living nuclei from hen erythrocytes, M. LASKOWSKI. (Minn. Expt. Sta.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 354-356).

Isolation of filterable virus from chickens affected with "blue comb" disease, E. F. WALLER. (N. H. Expt. Sta.). (*Science*, 95 (1942), No. 2474, pp. 560-561).—Observations on an outbreak in two flocks at the New Hampshire Station of the affection reported upon by Jungherr and Levine (E. S. R., 86, p. 96), known as pullet disease, blue comb, "X" disease, etc., are reported. Many of the birds were found dead without having been observed to be sick; others died after an illness of only a few hours. From the blood stream of such acutely affected birds from both flocks a filtrable agent was obtained that grows readily on the chorioallantoic membrane of chick embryos. One strain was carried through 56 transfers made at 72- or 96-hr. intervals and the other strain through 39 such transfers. A third strain obtained from the eggs of an infected flock is now in its seventh transfer. When the infected chorioallantoic membrane, embryo, or embryonic fluid is injected into susceptible chickens they, after 84 to 96 hr., become somewhat depressed and cyanotic. Death has not been produced by such an inoculation.

"A suspension of the feces and intestinal contents of experimentally infected birds is infective to other birds of the same age when given by way of the mouth. A bacterial-free filtrate of the feces is infective when injected intraperitoneally. Bacterial-free fecal filtrates are also capable of establishing the virus in incubating chick embryos. The virus is readily filterable through either or both the Seitz E-K 3 and the Chamberland-Pasteur L-3 filter."

Differential characters of two strains of *Clostridium botulinum*, type E: Action of toxins in chickens, E. L. HAZEN (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 1, pp. 112-114).—Descriptions are given of the differential characters of two strains of *C. botulinum*, type E, one isolated from German canned sprats and the other from Nova Scotian smoked salmon. Culturally they can be differentiated by colony formation on horse blood agar plates. Agglutination and absorption tests indicate them to be of distinct serologic groups. Tests for toxigenic activity demonstrated, however, that the toxins were not identical. Subcutaneous injections of both toxins uniformly gave rise to symptoms characteristic of botulism in guinea pigs, mice, rabbits, and kittens. White Leghorn chickens were highly susceptible to the toxin of the salmon strain but not to that of the sprat strain. In chickens 4 to 12 weeks old, approximately 6 to 8 guinea pig median lethal doses of the salmon toxin gave rise to fatal botulism, while doses of the sprat toxin several hundred times as large failed to kill or induce symptoms of botulism. The sprat toxin was demonstrable in the blood and also in the excreta of some of the chickens 72 hr. after inoculation.

Ineffectiveness of cow urine in the control of *Eimeria tenella* infection in chickens, H. FISHER, C. INKSTER, and J. BIELY (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 221-224).—In determining the effect of cow urine and its constituents on the course and development of coccidiosis in chickens, several groups of chicks were inoculated with *E. tenella* at the rate of 120,000 sporulated oocysts per chick. The inoculated chicks were studied to determine the effects of (1) urine on growth, (2) urine on coccidiosis, (3) varying amounts of culture, (4) hydrolyzed and unhydrolyzed urine, (5) urine fractions, and (6) urea.

Favorable differences were not observed in the virulence of coccidiosis in the treated and control groups. It was thus established that cow urine, various fractions of the urine, and urea did not protect growing chicks against lethal doses of *E. tenella*.

Transmission of virus of infectious tracheitis in chicken by contaminated egg shell. I. J. KLIGLER and M. PEREK (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 357-359).—Report is made on an infectious disease hitherto unobserved in Palestine which has been reported among chickens from different poultry farms. Its symptomatology resembles infectious laryngotracheitis, but it differs from this affection by its mild course, with absence of fatalities and of any noticeable effect on development. The disease is milder in young than in old chicks. Experiments demonstrated a virus to be transmitted on the surface of the eggshell.

Infection was most readily produced by dropping infected material into the trachea, also by intraperitoneal or intrathoracic inoculation. The incubation period varied with the age of chicks and the concentration of virus. One-week-old chicks showed the first symptoms of infection after 5 days; in chicks 2 weeks old, the incubation period was 9 to 24 days; in 6-8-week-old chicks the incubation period varied from 11 to 42 days. The infection spread quickly by contact. The time of exposure before appearance of symptoms (8-10-week chicks) ranged from 22 to 64 days. The virus could be demonstrated in the tracheal secretion in 1:1,000,000 in unfiltered and in 1:10,000 in filtered fluid.

A survey and study of spontaneous neoplastic diseases in chickens. C. OLSON, JR., and K. L. BULLIS (*Massachusetts Sta. Bul.* 391 (1942), pp. 56, pls. 12, fig. 1).—The results of a study contributing to the knowledge of the morphological characteristics of the various types of neoplasia and providing information on the relative incidence of the specific types are presented. They are based upon the histological examination of specimens received at the diagnostic laboratory and suspected of neoplastic disease at the time of necropsy. The collection included 384 cases of spontaneous neoplastic disease found in 365 chickens. An incidence rate of 12.9 percent for neoplastic disease was found in 2,304 chickens over 6 weeks of age that were examined in the laboratory. Twenty-five different kinds of neoplasms were found. Lymphocytoma was the most common and accounted for 55.5 percent of the 384 cases. Six other varieties (leiomyoma, embryonal nephroma, myelocytoma, leucosis, epithelioblastoma, and fibrosarcoma) accounted for 33 percent of the tumors. Each of the varieties of neoplasia is described, and the data are compiled for study. The incidence of neoplasia was studied in relation to various factors, such as age at necropsy, sex, seasonal occurrence, and breed. Each of these appeared to be of significance in one or more types of tumor. In some of the cases tentative diagnoses, based on macroscopic examination only, were later correlated with the final diagnoses in an effort to determine the accuracy of such tentative diagnoses. The results, together with sources of error, are discussed. The data on lymphocytoma provided a basis for a possible explanation of the different forms of this disease. Other neoplasms on which new information of significance was found were leiomyoma, neurogenic sarcoma, and carcinosarcoma. It may be concluded that spontaneous neoplastic disease in the chicken is relatively common and that, although lymphocytoma is the most common and causes the most loss, the other kinds are responsible for a significant share of the loss due to neoplasia.

A list of 29 references to the literature is included.

A large unilateral fibrosarcoma of the pectoral muscles of a fowl. E. P. SINGSEN and F. W. COOK. (*Univ. N. C.*). (*Poultry Sci.*, 21 (1942), No. 4, pp.

291-293, figs. 2).—Report is made of observations of a very large tumor which constituted 65.2 percent of the total weight of a young male bird. Grossly, it was firm to the touch, glistening, and mottled white, red, and yellow in color. Histologically it proved to be a fibrosarcoma.

An electrophoretic study of pullorum-agglutinating chicken serums, C. L. SAN CLEMENTE. (Mich. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 219-221, figs. 4).—An estimate was made of the electrophoretic mobilities and compositions of several pullorum-agglutinating chicken serums. The relative mobilities of the protein fractions of all samples were uniform, while the percentage concentrations of the protein fractions were relatively irregular for the doubtful and positive serums. The pullorum antibody is believed to be associated with the γ -fraction. The albumin concentration was decreased in serums of high titer.

A filtrable virus, the cause of a respiratory-nervous disorder of chickens, D. E. STOVER (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 207-213).—Report is made of the study of a respiratory nervous disorder of chickens, reported by Beach (*E. S. R.*, 84, p. 821), which has become increasingly important since its first appearance in northern California flocks early in 1940. Most of the affected birds were from 3 to 10 weeks of age, but some outbreaks were observed in younger chicks and in mature hens. "The respiratory phase of the disease was similar to infectious bronchitis, and it was difficult to differentiate between the two on the basis of symptomatology. It is probable that a flock may become affected with both diseases at the same time. Nervous symptoms of three general types usually were observed in each affected flock within a few days after the birds first began to show evidence of a respiratory disease. These were muscular incoordination involving particularly the neck and leg muscles, constant tremor of the body, and paralysis of the legs. The infective agent was present in the air sacs, lungs, and tracheas of the affected chickens and produced the disease in other chickens when inoculations were made intranasally, intratracheally, subcutaneously, or directly into the crop. The disease was transmitted by pen contact.

"Experiments have shown that infective material extracted from the air sacs, lungs, and trachea when suspended in physiologic salt solution and passed through Berkefeld V, N, or W filters produced the disease. These results demonstrated that the disease is caused by a filtrable virus. Studies showed that chickens refractory to infection with the virus of infectious bronchitis were susceptible to the virus of the respiratory nervous disorder. Chickens refractory to the respiratory nervous disorder were susceptible to infectious bronchitis in 50 percent of the cases tested. Chickens that were immune to the respiratory nervous disorder and to infectious bronchitis were shown to be susceptible to the virus of infectious laryngotracheitis and to coryza caused by *Hemophilus gallinarum*. The results of the cross-immunity experiments indicate that the virus of the respiratory nervous disorder is distinct from the virus of infectious bronchitis and from that of infectious laryngotracheitis."

The relationship between body temperature and genetic resistance to *Salmonella pullorum* in the fowl, J. C. SOHOLES and F. B. HURT ([*New York Cornell Sta. Mem.* 244 (1942), pp. 35, figs. 10).—The results of a series of studies with Rhode Island Red chickens on the physiological basis for resistance of fowls to *S. pullorum* led to the conclusion that differences in body temperature are responsible for differences in susceptibility of young chicks to this organism. The supporting evidence is as follows: "(1) By brooding chicks at 28° C. their body temperatures were lowered by amounts ranging from 0.7° to 1.4° F. below the temperatures of control chicks brooded at 35° C. These differences were

statistically significant at all ages up to 8 days after hatching. (2) In a series of 8 experiments chicks thus chilled were consistently more susceptible to *S. pullorum* than were controls brooded at 35° C. when both classes were inoculated on the day after hatching. In uninoculated controls at 28° C. mortality was insignificant. (3) By injecting sodium amytal the mean body temperature of chicks was lowered by 8.4° F. Recovery followed gradually and was complete 4.5 hr. after treatment. (4) In chicks with their body temperatures thus temporarily lowered by sodium amytal susceptibility to *S. pullorum* was higher than in inoculated controls not given the drug. (5) By exposing chicks to a 60-w. carbon-filament lamp at a brooder temperature of 38° C. their body temperatures were raised by amounts ranging from 1.26° to 2.10° F. above their temperatures when brooded at 28° C. and from 0.63° to 1.34° F. above the temperatures of controls kept at 35° C. (6) In 10 different experiments the resistance of chicks (thus subjected to artificial fever) was consistently greater than that of untreated controls when both classes were inoculated with *S. pullorum* on the day after hatching. (7) The average body temperature of chicks following inoculation was from 0.2° to 1.1° F. higher than that of uninoculated controls, but was more variable because the temperatures did not rise in all chicks. Of 397 inoculated chicks, 48 percent attained in the first 8 days a temperature of 107° F., whereas of 80 uninoculated controls only 3.75 percent reached that temperature. (8) Chicks that attained a body temperature of 107° F. following inoculation were more resistant than were those that did not. Even among the chicks that died, those with high temperatures lived longer than did those without. (9) In three lots of chicks brooded at 28° C. and inoculated when 1 day old the mean daily body temperatures from 1 to 8 days of age were consistently higher in the chicks that survived than in those that died. (10) In chicks not inoculated with *S. pullorum* until they were 2 or 3 days of age the body temperatures of those that subsequently died after infection were significantly lower, even before inoculation, than the temperatures of those that survived after infection. (11) Among chicks from different dams those with mean familial body temperatures higher than the average were more resistant to *S. pullorum* than were those with familial temperatures below the average. The families were first differentiated according to the temperatures of uninfected chicks. In 5 later experiments with inoculated chicks, the resistance of the high-temperature families was consistently and significantly higher than that of the low-temperature families. (12) From 2 to 10 days of age the body temperatures of White Leghorn chicks (which, as a breed, are comparatively resistant to *S. pullorum*) were consistently higher than those of Rhode Island Red chicks (which are comparatively susceptible). Moreover, when samples of both breeds were brooded at 28° C. the White Leghorns were better able to maintain and raise their body temperatures than were the Rhode Island Reds. (13) The body temperatures in chicks of both breeds were found to rise fairly rapidly in the first 8 days after hatching, as does also resistance to *S. pullorum*."

From all the evidence presented, the authors consider it reasonably certain that high temperatures and resistance to *S. pullorum* are not associated merely by chance, but that either the high temperatures or the greater adaptability of the temperature-controlling mechanism which these temperatures indicate, or both together, are responsible for the increase in resistance to *S. pullorum* which accompanies them. This effect is not necessarily attributable to the direct action of high temperatures upon that organism; it might result from their acceleration of the processes whereby the invading bacteria are destroyed.

The pathogenicity of *Aerobacter aerogenes* and *Escherichia acidilactici* for turkeys and their response to the agglutination test for pullorum dis-

case, H. BUNYEA and A. D. MACDONALD. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 306-310).—Tests made of experimental antigens on a flock of breeding turkeys are reported. The findings have shown that some strains of *A. aerogenes* and of *E. acidii lactici* are pathogenic for turkeys and poults and may be responsible for a considerable young poult mortality. The fact that these organisms possess some cross-agglutinating ability in the presence of pullorum antiserum, and vice versa, suggests the possibility that the presence of these infections in a flock of turkeys might tend to complicate the interpretation of the pullorum test. The predilection of the infections for the ovaries suggests the possibility of egg transmission of the infections. No definite proof of this has been developed, however. Although poults experimentally inoculated with bovine strains of *E. acidii lactici* were not shown to be susceptible to infection with laboratory cultures of the bovine organisms, yet it is conceivably possible that under field conditions young turkeys ranging areas or inhabiting buildings contaminated with virulent calf scour infection might become infected thereby. The findings indicate that the mammalian strains used in these studies may have become attenuated by prolonged maintenance in the laboratory.

Further observations on a blood protozoan of turkeys transmitted by *Simulium nigroparvum* (Twinn), E. P. JOHNSON. (Va. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 7, pp. 214-218, figs. 6).—Report is made of studies conducted in continuation of those noted (E. S. R., 79, p. 687). "In histopathologic studies of tissues from 21 turkeys infected with *Leucocytozoon smithi* and killed 24 hr. to 12 days after the injections, schizogonous stages of this protozoan were not found. From continued observations it is concluded that the gametocytes of this protozoan as observed in the blood of affected turkeys occur in the plasma and not in any host cell. In a further study of turkeys which were infected with this parasite and in which numerous gametocytes could be demonstrated in the peripheral blood for several months, when kept screened away from flies for a year gametocytes did not recur in their blood, while in control turkeys exposed to flies, gametocytes did recur, indicating that asexual reproduction of the parasite did not take place in the turkey. The oocyst stage occurs in the stomach wall of *S. nigroparvum* and not on the wall, as do malaria organisms in the mosquito. From this work it appears that the life cycle of *L. smithi* as it occurs in turkeys and in *S. nigroparvum* is as follows: Macro- and micro-gametocytes are taken into the stomach of these blackflies while engorging on blood from infected turkeys. These develop into macro- and micro-gametes, respectively, and after fertilization the resulting zygote uncoils in the stomach of the fly to become a motile ookinete which finds its way into the stomach wall, where it rounds up to become an oocyst. The oocyst, after maturing, ruptures to release sporozoites, which find their way to the lumen of the salivary glands of the fly. When the infected flies bite turkeys the sporozoites enter the blood stream, where they develop in the plasma into gametocytes."

Course of infections with the 3H2 strain of *Plasmodium cathemerium* in canaries, H. BECKMAN (*Soc. Expt. Biol. and Med. Proc.*, 50 (1942), No. 1, p. 90).—The author has found the 3H2 strain of *P. cathemerium* to be very virulent when transmitted (exclusively) through the bite of infected northern house mosquitoes.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Idaho Station] (*Idaho Sta. Bul.* 244 (1942), pp. 23-27).—These include studies of runoff and of the irrigation of potatoes with cold well and warmer canal waters, by H. Beresford,

M. R. Kulp, H. S. Riesbol, J. L. Toevs, and W. Watson; analysis of mechanized production of potatoes and beets and threshing various crops with a small combine, by N. B. Akesson and Beresford; the use of light in agriculture, by Akesson, Beresford, D. E. Brady, W. V. Halversen, and J. M. Raeder; farm frozen storage, by Beresford; and reduction in amount of cement required in concrete, by Beresford and W. R. Friberg.

[Agricultural engineering investigations by the Indiana Station]. (Partly coop. U. S. D. A. et al.). (*Indiana Sta. Rpt. 1941, pp. 21-30, 80-81, figs. 3*).—This report contains notes on a study of the suitability of earth stabilized with emulsified asphalt for farm building construction as applied to a poultry laying house, and poultry housing studies, both by I. D. Mayer and C. W. Carrick; atmospheric corrosion of wire and wire products, and factors entering into the storage of shelled corn with high moisture content in small wire-sided bins, both by Mayer; study of temperature, humidity, and air movement in a concrete dairy barn, by Mayer and J. H. Hilton; hydrologic studies and measurement of runoff from small watersheds, by R. B. Hickok, Mayer, H. Kohnke, and G. D. Scarseth; a study of the structural and economic factors involved in the use of plywood in hog houses and poultry houses, by Mayer, E. J. Kirsch, C. M. Vestal, J. H. Martin, and Carrick; studies with Purdue plow trash shields, and a study of a fertilizer attachment for plows, both by R. H. Wileman; investigations on weed control implements, by Wileman and O. C. Lee; seed corn drying investigations, by Wileman and A. J. Ullstrup; the use of electricity in brooding chicks, by T. E. Hinton, S. W. Hanners, and W. P. Albright; mechanical refrigeration of milk with units driven by gasoline engines and electric motors, by Hinton and R. L. Witz; use of mechanical refrigeration for cooling and holding eggs on the farm, by Hinton, Witz, and G. W. Newell; a study of the use and practicability of electric heat for warming drinking water for livestock, by Hinton, G. H. Foster, and C. F. Gobble; the use of electric heat in brooding early spring farrowed pigs, by Hinton, Foster, and C. M. Vestal; the development of portable driers for the dehydration of hay and grain, by W. Aitkenhead, Wileman, and Mayer; and power consumption and comparative costs of stationary and portable spraying and stationary v. portable spraying plants, by C. L. Burkholder and Hinton.

[Agricultural engineering investigations by the Puerto Rico Station] (*Puerto Rico Sta. Rpt. 1940, pp. 36-38, 93-97, figs. 4*).—The construction of split-bamboo fishing rods was found by J. K. Alvis and P. A. Folch to be an industrial possibility for Puerto Rico. A ditcher for use on sugarcane land was developed, and its first model worked satisfactorily in friable soils. Experimental essential-oil stills were completed, and an experimental solar drier effectively reduced the moisture content of bamboo wood.

Surface water supply of the United States, 1940, parts 9, 13, 14 (*U. S. Geol. Survey, Water-Supply Papers 899 (1941), pp. VI+294, pl. 1; 903 (1941), pp. VI+246, pl. 1; 904 (1941), pp. V+208, pl. 1*).—These papers record measurements of stream flow for the year ended September 30, 1940, No. 890 covering the Colorado River basin, No. 903 the Snake River basin, and No. 904 the Pacific slope basins in Oregon and lower Columbia River Basin.

Reduction of mineral content in water with organic zeolites, R. F. GOUDEY (*Amer. Soc. Civ. Engin. Proc., 68 (1942), No. 2, pp. 225-236, fig. 1*).—The development of improved organic zeolites for the removal of positive and negative ions, completely or in part, provides superior methods for softening water, reducing sodium content, removing excess alkalinity, lowering sulfates, or reducing chlorides to produce suitable water for domestic, irrigation, and industrial

uses, and in special cases where inconvenience, expense, or failure to secure an adequate working plan are involved. Although the costs of operation in the more aggravated cases may be relatively high, they are, in most cases, not prohibitive and are certain to be lower as increased production and availability of suitable materials develop. A quality comparable for many purposes with that of distilled water can be produced by treatment with organic zeolites.

The grease problem in sewage treatment, A. L. FALES and S. A. GREELY (*Amer. Soc. Civ. Engin. Proc.*, 68 (1942), No. 2, pp. 193-209, fig. 1).—The quantity of "grease" found in sewage by the present standard method of analysis is largely dependent upon which of the three standard solvents is used for extraction. Furthermore, the standard method of determination of grease in sewage has proved not entirely satisfactory in other ways. The following steps appear to be desirable: (1) Agreement upon what substances should be included in the term grease, (2) adoption of a standard method for determination of grease in sewage as thus defined, and (3) accumulation of data based upon this standard method.

A considerable proportion of the ether-soluble matter can be removed by sedimentation and plain skimming. A somewhat larger proportion can be removed if the sewage is aerated prior to sedimentation and skimming. Aero-chlorination prior to sedimentation and skimming accomplishes a still larger removal of grease. At present, however, available operating data are insufficient to form a basis for a sound conclusion as to the value of preaeration and of aérochlorination in the over-all removal of grease from sewage.

Reduction of irrigation water losses, O. W. ISRAELSEN (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 2, pp. 6-7, figs. 4).—Of conveyance losses, seepage is the greatest and probably cannot be entirely prevented. The points of greatest seepage can be located, however, and the ditches lined with clay or the like at these points. Transpiration losses through vegetation along the canal bank and vegetative or other obstructions in the canals can be dealt with more promptly. Irrigating on the basis of examination of the soil to ascertain actual need rather than on that of the "watering turn," which wastes such water as is applied when the soil is already wet, could save much water. The best irrigation practices are considered seldom to store in the soil root zone more than 75 percent of the water delivered to the farm. The major cause of low water-application efficiencies is the application of excessive depths of water in single irrigations. A depth of 6 in. is usually quite enough, and on shallow soils it is too much. Careful control of the size of stream, avoiding excessively long runs, frequent transfer of water from one plat to another, careful inspection of depth of water penetration, use of runoff of high land to irrigate lower lands, or better still, prevention of runoff completely are some of the means by which irrigators can increase water-application efficiencies. Other important measures are to avoid runs of 660 ft. or longer, to apply the water at a rate greater than the rate of infiltration into the soil, to avoid land slopes of 3 percent and higher in the direction of the flow of the irrigation stream, not to let the water concentrate into large streams on parts of the farm and thereby cause erosion and gullyng, to measure the stream or get the water master to measure it, and to keep records of the depth of water applied.

1941 Supplement to A. S. T. M. Standards, including tentative standards.—II, Nonmetallic materials—constructional (*Philadelphia: Amer. Soc. Testing Mater.*, [1941], pt. 2, pp. XIV+427, figs. [55]).—This second supplement to part 2 of the 1939 A. S. T. M. Standards contains the 39 newly adopted and 37 revised standards and the 15 new and 35 revised tentative standards in the nonmetallic constructional materials field that have been accepted since the appearance of the first supplement, issued in November 1940.

The Utah snowmobile: This machine provides power transportation over snow-covered areas and may be of use to the Army for such purposes, G. D. CLYDE (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 2, p. 5, figs. 3).—This device is provided with a split endless track running over six rubber tires, the middle set of wheels being somewhat lower than the other two pairs so that the machine tends to pivot on the middle pair. Steering is accomplished by means of a small runner outrigger in front of the machine and operated by the steering wheel in the cab. In snow survey work the machine carried 11 men and their equipment weighing about 1,500 lb. a round trip of about 12 miles in about 3 hours' driving time over a course at elevation 8,250 ft. and grade which, in some instances, reaches 25 percent. The snow was soft in the timber and crusted in the open.

The total area of the tracks is approximately 32 sq. ft., and the maximum weight of the equipment with its load, exclusive of that carried as the guiding runners, is about 2,000 lb. This equipment can therefore be operated on very light snow as the weight is less than 0.5 lb. per square foot. In very loose soft snow the tracks settled as much as 20 in., but no stalling of the motor occurred. The sled was powered by a 65-hp. Chevrolet motor and a 1.5-ton rear end. The transmission was geared for a compound low speed, which gave ample power under the most adverse conditions. It is believed that this type of equipment will solve the problem of power transportation over snow-covered areas and should be of greater interest to the Army as well as irrigation, power, and municipal water users.

Adapting horse-drawn mowers to tractor power, L. E. HIGHTOWER (*Missouri Sta. Cir.* 217 (1941), pp. 4, figs. 5).—The author notes that the mower attached to the tractor should not be hitched directly to the end of a stub tongue. The brace bar beneath the frame extends downward at an angle, and in heavy cutting an upward thrust is produced. This tends to lift the weight of the mower frame off the wheels and thereby cause slippage. A drawing shows an arrangement which permits the mower to be pulled from the regular doubletree hitch. About one-half the force required to pull the mower is applied, through the draft rod, to the yoke of the cutter bar. This type of hitch allows much heavier cutting to be done without adding weight to the mower to provide traction. Square turns are possible if the regular tractor drawbar is extended backward about 18–20 in. in a manner illustrated. The tractor must be turned very short just as the rear tractor wheel clears the corner of the land. It may be necessary to use the right wheel brake. It is not necessary to stop the tractor, and it is usually not necessary to lift the cutter bar on square corners. Some safety device should be provided in the hitch unless the operator is sure the cutter bar will encounter no obstruction. Figures show one very simple type of safety device which consists of a small rivet or nail which shears and allows the drawbar extension to slide through the clamps which hold it to the tractor drawbar. A satisfactory arrangement for lifting the cutter bar from the tractor seat is illustrated.

Plow adjustment and operation, M. M. JONES and L. E. HIGHTOWER (*Missouri Sta. Cir.* 232 (1942), pp. 23, figs. 30).—The authors describe and illustrate sharpening of plowshares—the chilled iron type by grinding, the steel by heating and hammering—to restore down suction and side suction, give brief directions for hardening soft-center shares, and mention the hard-surfacing of steel shares by adding suitable material to the points and cutting edges with the aid of the welding torch. With respect to hitching for minimum draft they discuss and illustrate center of resistance and the importance of so hitching as to pull straight ahead from this point. Hitching adjustments for tractor plows are

taken up in detail with numerous diagrams. Other main topics are rear wheel adjustments, coulters, walking plows, and horse-drawn riding plows. General suggestions and hints on plow adjustment and operation conclude the treatment.

Spray machinery for home orchards, gardens, and truck crops, T. E. ASHLEY (*Mississippi Sta. Cir. 106 (1942), pp. 18, figs. 15*).—The author describes various commercial types of hand- and power-operated sprayers; gives details of the construction and operation of a hand-pump barrel sprayer converted for $\frac{1}{2}$ hp. gasoline motor drive, of which set-up a similar description has previously been published (E. S. R., 82, p. 263), together with directions for making a hemicylindrical horizontal sprayer tank; takes up nozzles for sprayers; briefly notes dusting equipment and its use; and adds some discussion of spraying schedules for various fruits.

A new castor-bean sheller, H. A. ARNOLD and M. A. SHARP (*Tennessee Sta. Bul. 179 (1942), pp. 12, figs. 7*).—The authors redescribe a device already reviewed elsewhere (E. S. R., 87, p. 125).

Dairy engineering, A. W. FARRALL (*New York: John Wiley & Sons; London: Chapman & Hall, 1942, pp. XV+405, figs. 190*).—This treatment of the subject is directed primarily to the operator and to the student without technical engineering training. Material has been drawn from the author's experience as a teacher of dairy engineering and from his research on dairy machinery in a large dairy-equipment manufacturing company as well as from previously published data. The contents are: Physical and chemical properties of milk; simple mechanical principles; power transmission; electrical power and equipment; hydraulics and pumping; heat measurement, transfer and control; steam and its use in the dairy; principles of refrigeration; insulation and cold storage rooms; heaters—coolers and heat-exchange equipment; ice cream freezing equipment; homogenizers; pasteurizing equipment; evaporating and drying equipment; can washing and sterilizing equipment; bottle washers and fillers; cream and butter handling equipment; cheese and casein plant equipment; equipment maintenance; pipe, pipe fittings, fitting, and soldering; and dairy plant design, layout, and utilization. An appendix, consisting of numerical data in common use, some physical constants of metals and other materials, and other physical data likely to be of use in dairying applications of refrigeration engineering, electrical power, etc., is also included.

"Gascolgne" auto-releaser milking plant, E. H. LAMB and F. H. JORDAN ([*Gt. Brit.*] *Min. Agr. and Fisheries, Agr. Mach. Testing Com. Certif. and Rpt., 73 (1942), pp. [4]+10, figs. 2*).—This report covers the performance of a complete set-up of milking equipment of four stalls and a building provided for the tests. The trial was continued through 15 mo. with generally very satisfactory results. The special feature of the equipment, the "auto-releaser", consisted essentially of a metal cylinder counterpoised, when empty, in the horizontal position, but tipping to a position about 30° from the horizontal after filling with milk. The tipping operated means for shutting off the flow of milk and the vacuum lines from the cylinder and for opening a large diaphragm valve at the lowered end of the tipped cylinder so that its contents were emptied into a receiving vat. The counterpoise then returned the cylinder to the horizontal position, completing the cycle of movements by reopening the milk flow and vacuum line.

The over-all report is that the lay-out of the plant is compact, labor-saving, convenient, and gives reasonable comfort for the cows. Under the conditions of the test the plant gave generally satisfactory results. Its general mechanical efficiency was good.

Air conditioning for houses in California, H. S. GORDON and R. L. PERRY (*California Sta. Cir. 351 (1942), pp. 48, figs. 13*).—The subject matter is separated into the four general divisions (1) the physiological principles of air conditioning and the optimum conditions desired, (2) the loads and requirements to be satisfied (heating and cooling loads which will be required for different climatic and internal conditions for various types of building construction and the requirements of air movement, purity, and humidity), (3) fulfillment of air conditioning requirements, and (4) equipment for comfort cooling and air conditioning. The last-named division takes up attic fans for ventilation and night air cooling, evaporative cooling, cooling with well water and with ice, complete air-conditioning equipment, cost of air-conditioning equipment, and unusual applications (the final subtopic indicating the general principles of reverse-cycle heating and of panel heating and cooling). The general treatment is nontechnical, and a glossary of the more technical terms employed is appended.

Keeping your house in repair, A. F. COLLINS (*New York and London: D. Appleton-Century Co., 1941, pp. XVI+314, figs. 121*).—The author states that this book was written "for the man of moderate means who owns his house and who would rather keep it in repair himself than to suffer the slings and arrows that are his lot when he hires the average mechanic to do the job for him." Practical directions for selecting the most suitable tools and materials and for making both minor and major repairs and renovations are given, the following being the specific subjects covered: Making carpentry repairs, making roof repairs, masonry and plastering repairs, making stucco and concrete repairs, painting the outside of your house, finishing the inside of your house, papering the rooms of your house, making glazing repairs, repairing the plumbing system, repairing your heating plant, repairing the electric installation, and repairing builder's hardware. Chemical formulas having almost no relation to the actual chemical composition of the compounds named appear on pages 115 and 128.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Idaho Station, 1941] (*Idaho Sta. Bul. 244 (1942), pp. 27-29, 50*).—In addition to findings previously noted, there are included a brief statement by N. Nybrotten and P. A. Eke based on interviews with 180 settlers as to the need for capital and credit by settlers on the raw lands in the Black Canyon irrigation project in Canyon and Payette Counties; findings by Nybrotten as to the relation of wheat yields to selling values of land in the Palouse area; a brief statement by L. Fenske as to the cost per acre of operation and management, the costs per unit of grazing and the carrying capacity, etc., of improved pastures of different kinds; a brief statement of findings by Eke and R. Brown as to prices paid for butterfat and cream in Lewiston, Idaho, Spokane and Seattle, Wash., and Portland, Oreg.; and causes for cull grades of potatoes, by J. E. Kraus and J. L. Toevs.

[Investigations in agricultural economics and farm management by the Indiana Station, 1941]. (Partly coop. U. S. D. A. et al.). (*Indiana Sta. Rpt. 1941, pp. 48, 67-68, 69-73, 87, 96-97, fig. 1*).—In addition to findings previously noted, brief statements are included as to the following lines of work and findings: Livestock marketing from farm to processor, by J. R. Wiley, T. K. Cowden, and D. L. Henry; size of farms in central Indiana and costs of operating tractors, both by J. C. Bottum; rehabilitation farms and cost of production of tobacco, both by F. V. Smith; costs and practices in producing grains and sod crops, by Bottum, L. E. Slater, G. P. Walker, and T. M. Bushnell; economics of poultry production, by E. C. Young, J. W. Oberholtzer, and E. R. Menefee;

cost of keeping dairy sires in northwestern Indiana, by L. S. Robertson, Slater, V. C. Manhart, and G. A. Williams; marketing dairy products, by Cowden and C. M. Hardin; farm tenure during changing price levels, Indiana farm tenure by type-of-farming areas, and landlord-tenant compensation, all by O. G. Lloyd and H. S. Morine, Jr.; relation of slope and erosion to farming adjustments and land use on farms in the southern Indiana limestone area, by Smith; farm labor, by Young, Robertson, and B. R. Bookhout; a historical analysis of farm prices in Indiana, by E. L. Butz and H. J. Houk; selling tomatoes on a graded basis, by F. C. Gaylord and K. I. Fawcett; a study of the retail egg markets in Indiana, by Menefee and Cowden; and Federal-State egg inspection service, by Menefee and G. W. Newell.

[Investigations in agricultural economics by the Mississippi Station] (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 5, pp. 1, 7, 8).—Included are two articles by M. Guin on High Prices Reflected in Higher Farm Income (pp. 1, 7) and Income and Profit Increase on Truck Farms (p. 8).

[Investigations in agricultural economics by the North Dakota Station] (*North Dakota Sta. Btmo. Bul.*, 4 (1942), No. 5, pp. 21-23, figs. 2).—Included are articles by W. L. Ettesvold on (1) The War Presents Problems in Livestock Marketing (pp. 21-22), with charts showing how different kinds of livestock were moved from farms in North Dakota in 1940 and the average size of sales, and (2) North Dakota Farm Prices (pp. 22-23), showing the average prices received by farmers for 14 commodities on April 15, 1942, with comparisons with earlier dates.

Current Farm Economics, [June 1942] (*Oklahoma Sta., Our. Farm Econ.*, 15 (1942), No. 3, pp. 73-106, figs. 2).—In addition to the usual discussion of the agricultural situation and the usual tables of prices, price indexes, etc., the following articles are included: Dairy Marketing in Oklahoma, by A. L. Larson and D. C. McWhorter (pp. 79-85), discussing the importance and location of the industry, use made of products, marketing agencies, etc.; Large Scale Business Management in Farming, by P. Nelson (pp. 85-86); and An Analysis of the Public Finance Situation in Rural School Districts in Oil-Producing Areas, by L. A. Parcher (pp. 87-101), presenting data and discussing the actual difference in the public finance situation in school districts with and without oil development. Oil development causes an increase in population and encourages or requires an increase in expenditures and debt. Corporate and personal property are much more important as sources of revenue in the districts where oil is found. Net debt is higher in the oil districts, but the ratio of debt to valuation is not unusually high. In spite of higher taxes in the oil districts, tax delinquency is less than in nonoil districts. The per acre levy on land is slightly higher in the oil districts.

Land-use adjustments needed on farms in Deer Creek Township, Cass County, Indiana, B. R. HURT, E. C. YOUNG, and L. ROBERTSON. (Coop. U. S. D. A.). (*Indiana Sta. Bul.* 466 (1942), pp. 32, figs. 12).—This study is based on land-use data for 156 farms for the period 1932-36. The farms were divided into three groups on the basis of the dominant soils—dark upland, light upland, and mixed soils—and each soil group was further divided into three groups on the basis of size—99 acres or less, 100-174 acres, and over 174 acres. A typical farm in each size group in the dark and light upland soil groups was studied in detail. The area and the land-use pattern of the farms in it are described. The desirable land-use adjustments needed, the representativeness of the typical farms selected, the changes in farm organization and practices required to facilitate desirable adjustments, the directional effects of land-use adjustments on number and types of livestock, and the possibilities of carrying out the needed

adjustments are analyzed and discussed. Changes needed in organization are outlined for a 120-acre farm needing little adjustment and a 140-acre farm needing much adjustment. An appendix includes a description by T. M. Bushnell of the minor soil types in the township.

Of the farms on the dark upland soils, one-fifth needed almost no adjustment, three-fifths only minor adjustments, and one-fifth extensive revisions of the cropping systems. For the farms on light upland soils, the proportions were one-sixth, one-half, and one-third, respectively. The farms on the mixed soils needed drastic adjustments to keep erosion losses to a minimum. The principal adjustments needed for the township as a whole are a slight decrease in corn acreage; a considerable increase in sod legumes, particularly alfalfa and mixed pasture; some substitution of wheat for oats; removal of stock from land to be kept in woods; increased use of lime and fertilizers; adaptation of layout and field operations to physical features of the land; and a slight increase in the total livestock. Approximately 38 percent of the farmers lack financial means or managerial ability (chiefly financial means) to put the needed changes into operation. It is estimated that immediate income on 60 percent of the 156 farms would be reduced if the recommended land-use adjustments were carried out under average management but that incomes over a longer period would be increased.

Farming adjustments and agricultural conservation programs in West Virginia, F. D. CORNELL, JR., and C. W. CRICKMAN. (Coop. U. S. D. A.). (*West Virginia Sta. Bul. 304* (1942), pp. 40, figs. 5).—The study deals with farm-management problems in the area which includes Upshur, Harrison, Lewis, and Braxton Counties, and is typical of the larger livestock-grazing area in the northern and west-central part of the State. Particular attention is paid to the adaptability of the State agricultural conservation program and of the Upshur County experimental program. The outstanding feature of the experimental program was the requirement that part of the soil-building practices be carried out on pastures. Other features were that (1) payments for the application of superphosphate were made only where the land had been limed the same year or in the preceding 5 yr., (2) payments for seeding were made only where the land had been limed within the same or preceding 5 yr. and treated with superphosphate within the same or preceding year, and (3) arrangements were made by which farmers participating could obtain lime and superphosphate in lieu of payments. The area and types of farming and farm organizations are described. The pasture and low-income farm problems are discussed. The participation under the State and the experimental programs are analyzed and discussed. Some of the findings were:

Any program well suited to the needs of one county should be reasonably well adapted to all counties in the same type-of-farming area; the experimental program, in spite of its additional requirements, was accepted with little opposition; this program was instrumental in bringing about much more pasture improvement in Upshur County than in adjacent counties under the State program; the supplying of conservation materials in lieu of payments greatly stimulated their use, both as to amount and widespread application; the effects on pastures from the applications of lime and superphosphate resulted in enthusiastic support in Upshur County for a regular plan of pasture improvement; because of small farm allowances and the fact that small farms were among the last to cooperate in the program, the low-income farms probably benefited least from the programs; more emphasis on the educational phase of the program would be beneficial; and personal interviews were the most satisfactory source of information on the programs.

•

Ranch organization and management in the granite area, E. C. VOORHIES, L. A. CRAWFORD, R. L. ADAMS, and G. A. CARPENTER (*California Sta. Bul. 663* (1942), pp. 83-95, fig. 1).—The ranch management in the region surrounding the San Joaquin Experimental Range of the U. S. D. A. Forest Service is discussed in sections covering the development of the cattle industry, size of business and of breeding herd, feeding and breeding practices; stocking the range, calf crop, death losses, dehorning and branding, weaning, culling practices, other livestock enterprises, and flexibility in ranch management.

Measuring the productive value of pastures, H. J. L'HOTE (*Missouri Sta. Bul. 443* (1942), pp. 34, figs. 9).—The major objective of this study was to develop a method for measuring pasture productivity under farm conditions. The method adopted embodied "the determination of the feed requirement necessary to maintain the livestock and to produce the gains and products on pasture. The feed fed while the animal is on pasture is deducted from this requirement and the residual is the amount contributed by the pasture and therefore measures the pasture yield." Another phase was the determination of pasture animal unit values for various classes of livestock. This was done on the basis of value of pasture per head per day and per head for the pasture season. Data were obtained for seven areas representative of the major soil and type-of-farming areas of the State and included 364 permanent pastures (9,837 acres), 155 rotation pastures (1,952 acres), and 5,667 acres of supplemental pastures. The areas, the monthly rainfall and pasture conditions, 1936-38, and the methods of computing the productivity of the pastures and the value of pasture to various classes of livestock are described. The significance of pasture production and the potential pasture production in the State are discussed.

The yields per acre of permanent pastures in 1937 in corn equivalent on the different types of soil varied from 8 to 18.1 bu., averaging 11.2 bu. "The most productive rotation pastures were Sudan, second-year sweetclover, and barley pastured out. These crops may be expected on the average to give a return of 20 bu. of corn equivalent or more. A second group of medium productivity would include timothy, oats and Korean lespedeza, timothy and Korean lespedeza, rye, wheat, first-year sweetclover following small grain, and Korean lespedeza following small grain. These crops may be expected to yield between 10 and 20 bu. of corn equivalent. Crops yielding under 10 bu. of corn equivalent are mostly in the class of supplemental pastures. The more important ones in this group would be Korean lespedeza alone, rye pastured and harvested, pasture in small grain stubble, and pasture on timothy and clover meadow following the harvest of the hay crop." The potential pasture production for the State is estimated at 213,500,000 bu. of corn equivalent.

"The results of this study in addition to showing specific values for various pastures indicate two additional important facts. The first of these is that pasture production can be practically determined by this method of differences or by subtracting the supplemental feed received by animals on pasture from the normal feed requirement to maintain the animal and produce the gains which are realized while on that pasture. The second important fact is that pasture production under farm conditions will be materially less than that secured under very highly controlled experimental conditions, because farmers are not usually in a position to procure as nearly complete utilization without overgrazing as is true under experimental conditions."

Feeder cattle and sheep shipped into Minnesota, K. BJORKA, A. A. DOWELL, and G. ENGELMAN. (Coop. U. S. D. A. et al.). (*Minnesota Sta. Bul. 359* (1942), pp. 24, figs. 20).—Tables and charts are presented and discussed showing for

feeder cattle and sheep the volumes received, proportions bought at public stockyards and direct from other States, the ranks as to shipments of the stockyards and other States, the seasonal and geographical distribution of the shipments, and the relationship between incoming shipments and marketings.

During 1936-40 the incoming shipments of feeder cattle amounted to about 18 percent of the marketings; of sheep, they were about 42 percent. The largest shipments of both were in the months of August to October, but considerable numbers of feeder cattle were received in July and November. Of the feeder cattle, 57 percent cleared through public stockyards and 43 percent came direct from other States. Direct shipments of sheep amounted to 67 percent. The largest numbers of both cattle and sheep were fed in the southwestern part of the State.

Reducing the cost of producing dairy and poultry products in Missouri, B. H. FRAME (*Missouri Sta. Cir.* 237 (1942), pp. 7).—The possibilities of reducing costs are briefly discussed under the headings interest and taxes, miscellaneous charges, housing and equipment, labor, and feed.

Problems in marketing Utah fruits and vegetables, W. P. THOMAS, G. T. BLANCH, and A. L. STARK (*Farm and Home Sci. [Utah Sta.],* 3 (1942), No. 2, pp. 1, 8, figs. 2).—Brief summaries are made of an investigation of the economic position of Utah fruits and vegetables on out-of-State markets and of a business analysis of the 1941 peach and cherry deals handled by cooperative marketing associations of the State. Information for the first study was obtained "largely by interviewing brokers, commission men, wholesalers, and retail handlers of fruits and vegetables and by observing Utah products on the markets in comparison with products from competitive production areas." The second study analyzed the efficiency of the business organizations which marketed most of the 1941 crop of peaches and cherries. "Attention was also given to the volume of Utah's production of fruits and vegetables and its distribution." The need for improvements in marketing fruits and vegetables in the State is discussed, and the essentials for a general program are outlined.

Production and prices of milk in the Springfield-Holyoke-Chicopee milkshed in 1935, A. A. BROWN and M. BOOTH (*Massachusetts Sta. Bul.* 389 (1942), pp. 32, figs. 6).—This is the third of a series of bulletins (F. S. R., 81, p. 724; 82, p. 269). The first part describes the milkshed in sections covering the geography, the area, exclusiveness of the milkshed, disposal of commercial production, number and distribution of producers among market groups and throughout the milkshed, premium milk, the significance of scale of production, and the importance of transportation and cartage rates. The second part analyzes and discusses the producers' farm prices. It includes tables and charts showing the average prices by areas; the average net prices by areas; the average prices f. o. b. for 3.7 percent grade B milk paid by dealers in three selected areas; a comparison of the weighted average of 3.7 f. o. b. prices for the three areas adjusted for charges with dealer's product costs; analysis of variance in milk prices received by 1,174 producers; the statistical measures of the effect of ratings when the sum of producer's ratings is approximately equal to the dealer's class 1 sales and when about equal to dealer's purchases from producers; a summary of price analysis of two groups of 29 shippers having a ratio of ratings to dealers of less than 90 and of 95-104 percent; distribution of prices received by full-time producers of grade B milk in three selected areas; and a comparison of prices received by shippers in three areas. The findings in the three studies are reviewed, and pricing f. o. b. the farm rather than f. o. b. the city is discussed.

Economic analysis of the Weber Central Dairy Association, W. U. FUHRMAN, H. H. CUTLER, and W. P. THOMAS (*Utah Sta. Bul.* 301 (1942), pp. 42,

figs. 8).—The objective of this study was to ascertain the factors affecting the marketing of dairy products and the relationship of marketing to production. The report describes the association, a cooperative organized in 1923, and analyzes the financial history and the methods used in marketing sweet cream, butter, powdered milk, and market milk. The first section on financial history and organization deals with borrowings, building up membership equity, percentage of assets owned by members, capital and current ratios, interest and equity payments to members, and loans to producers. The second section discusses the number of patrons and the butterfat deliveries per patron, yearly and monthly butterfat receipts, receipts from local associations, butterfat receipts in milk and cream, and the distribution of butterfat by departments. The third section deals with production and distribution costs and returns by departments and discusses the major expense items, the basis of assigning charges to departments, the expenses per pound of butterfat, the costs of processing market milk and manufacturing and selling powdered milk, departmental losses and profits, net profits per pound of butterfat by departments, returns to patrons, etc. Appendix tables show the monthly prices paid for butterfat in milk for 1928–30 and 1932 and 1933, in grade A, B, and C milk for 1931 and 1934–38, in all cream for 1928–30, and in sweet and sour cream for 1931–38.

Financial management analysis of farmers' cooperatives in Michigan, H. E. LARZELERE (*Michigan Sta. Spec. Bul. 315 (1942), pp. 96, figs. 11*).—"The general purpose of this study was (1) to obtain and analyze data relative to the nature and volume of business and to the capital structure of various types of cooperative marketing and purchasing associations in Michigan, (2) to compare the financial condition of Michigan cooperatives, and (3) to develop selected management ratios for the use of managers and directors of cooperative associations in formulating policies and in controlling operations." It is based on data mostly for the year ended June 30, 1937, collected by the St. Paul Bank for Cooperatives assisted by the station. In the analysis the associations are divided into 11 groups according to the major type of service performed, consisting of 55 dairy, 31 livestock, 25 grain, 21 fruit, 23 potato, and 3 miscellaneous marketing associations; 30 associations the business of which was about equally divided between the marketing of produce and the sale of supplies; 67 associations selling farm supplies chiefly; 20 associations handling petroleum and consumer merchandise; 3 milk-bargaining associations; and 5 federated commodity exchanges. The different types of associations and their locations are described. The volume of business and methods of operation, sources of capital and methods of financing, the financial condition of the local cooperatives as reflected in the average balance sheets and in the operating statements for the different types of associations, and the policies in the disposition of earnings are analyzed and discussed. Seven management or sales ratios—sales to net earnings, to gross margin, to expenses, and to total assets, revenue to fixed assets, supply sales to accounts receivable, and cost of goods sold to inventory—and four financial or balance sheet ratios—current assets to current liabilities, inventory to accounts receivable, and net worth to total capital and to fixed assets—were used to measure the financial condition and operating efficiency of the associations. An appendix includes tables showing the methods of operation in the various types of associations; number of associations having various forms of membership equity; secondary sources of credit used by the associations in 1936; short-term commodity, operating capital, and facility loans outstanding in 1936; and the proportion of total assets represented by notes payable and long-term liabilities for different types of associations in 1937.

World wheat survey and outlook, May 1942, J. S. DAVIS (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 18 (1942), No. 8, pp. [2]+339–366, figs. 6*).—

"Huge wheat surpluses in all four chief exporting countries and varied but growing bread shortages in Europe (outside the United Kingdom) continue to dominate the world wheat position. War developments since December 7 have influenced it mainly by making shipping scarcer, stopping the flow of basic products from the Southwest Pacific, and spurring the United States to all-out efforts as a leading partner in the United Nations. In this country, political measures have boosted wheat prices to levels suggestive of shortage instead of embarrassing abundance. The Commodity Credit Corporation, having been hampered in disposing of its owned stocks and having acquired well over half of the 1941 wheat put under loan, will control some 60 percent of the carry-over of 610-650 million bushels. Advance steps are being taken to cope, as best may be, with the storage crisis that harvesting the big crop of winter wheat will bring. . . . Japan now controls the rice-surplus areas of Asia. By contrast, the European Axis and neutral countries are weak in bread-grain supplies, in which the United Nations are exceptionally strong."

The fruit industry of Argentina, F. A. Morz (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr. Rpt. 1 (1942), pp. [2]+102, figs. 44*).—The fruit industry of Argentina is discussed in sections on the production and marketing of deciduous fruits, of grapes, and of citrus fruits and Argentina as a market for American fruit. The section on deciduous fruits deals with the quantity and variety of production, the fruit regions, production practices, harvesting dates, packing and packing facilities, cost of production and prices, transportation and cold-storage facilities, markets and marketing methods, Government inspection service, canning and drying industries, trends and general outlook, etc. The section on grapes discusses the producing regions, production practices, yields, harvesting dates, packing, costs of production and marketing, marketing, and future prospects. For citrus fruits the description covers the producing regions, growth of the industry, rootstock problems, cultural practices, production costs, yields, grading and packing, marketing season, markets, selling prices, and prospects for the industry.

The author states that Argentina as an important outlet for American fruits is extremely doubtful and decidedly remote because of the excessive tariff barriers, exchange restrictions, and high freight rates; that United States exports to Argentina declined nearly 93 percent from 1929-30 to 1938-39; that trade agreements of October 14, 1941, between the United States and Argentina may restore some of the trade lost; that only about 10 percent of the population of Argentina, mostly in Buenos Aires, has sufficient purchasing power to buy United States fruits; that assuming all trade barriers in Argentina were removed it is doubtful whether takings of United States apples and pears would exceed half a million boxes annually; that Argentina is a doubtful potential market for California grapes as the landed cost is prohibitive and the demand is restricted entirely to a limited luxury-class trade; and that exports of fruits to Argentina are limited to a few varieties popular on its markets.

The fruit industry of Brazil, F. A. Morz (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr. Rpt. 2 (1942), pp. [2]+45, figs. 17*).—The fruit industry of Brazil is discussed in sections on fruits other than citrus (Temperate Zone and tropical fruits), citrus fruits, cultural practices of the citrus industry, disposal of the citrus crop, and Brazil as a market for American fruits.

In summarizing it is stated that Brazil is capable of producing an almost unlimited variety of fruits; that from a commercial point of view pineapples, bananas, and oranges are the most important fruits produced or are those entering export channels; that commercial development of citrus fruit, especially oranges, has taken place rapidly and on a large scale during the last few years;

that this development can go on almost indefinitely; and that without a great deal of effort Brazil could produce more than the world's requirements of summer oranges and could almost supply the year-round requirements.

"The possibility of developing an important market in Brazil for American fruit is very doubtful. Apple exports to Brazil under normal trading conditions in the pre-war years 1936-37 to 1938-39 averaged about 1.5 percent of the total United States export business, and pears average about 3.3 percent. While it is believed that exports to Brazil could be increased slightly, provided certain conditions were met, the volume moved could in no way replace or even approach the shipments made to certain European countries."

The fruit industry of Chile, F. A. Motz (*U. S. Dept. Agr., Off. Foreign Agr. Relat., Foreign Agr. Rpt. 3 (1942), pp. [2]-46, figs. 10*).—The several sections discuss the land and the people; the fruit-producing regions; the varieties, extent of season, production, and exports of apples, pears, plums, peaches, apricots and nectarines, grapes, melons, citrus fruit, and miscellaneous tree fruits; the cultural practices; harvesting, storage, and marketing; canning and drying industries; and the United States in relation to the Chilean fruit industry. The following statements are made regarding the United States in relation to the Chilean fruit industry:

"Because of its small population with very limited purchasing power, Chile offers but little encouragement as a market for United States fruit. High production costs and transportation charges on American fruit practically eliminate Chile as an outlet for any volume of fruit from the United States. Domestic supplies of apples and pears are available in Chile throughout the greater part of the year, and during the off season the trade is supplied with canned and dried fruits, which are of good quality and cheap. Early fruits and vegetables are on the market when storage supplies are no longer available. Since Chilean exports to neighboring South American countries have been decreasing and exports to Europe increasing, the European war is having a serious effect upon the industry. Supplies that are ordinarily destined for overseas markets have to be disposed of locally, which brings up the problem of wider distribution on local markets and extension of the marketing period. With only about 4.5 million inhabitants, nearly 25 percent of which live in two cities, Chile can boast of no large consuming centers. The envy of the average Chilean fruit grower is the market of 130 million people in the United States, all of whom are regarded as potential consumers of Chilean fruits. Instead of offering a market for American fruits, Chile is looking toward the United States as an outlet for its surpluses."

RURAL SOCIOLOGY

Some cultural factors related to occupational mobility among Wisconsin farmers, G. W. HILL and H. T. CHRISTENSEN. (*Univ. Wis. et al.*). (*Rural Sociol.*, 7 (1942), No. 2, pp. 193-200; *Span. abs.*, pp. 193-194).—"Based upon a field survey of Wisconsin farm families, this study shows that farm boys are entering nonfarm occupations to a greater degree than formerly and that their movement is influenced by a number of cultural factors. Nearly two-fifths of the farm-reared boys of today are in nonfarm work, as compared with about one-fifth two generations ago. Desertion of farming as an occupation is greater in families of low economic status. Nationality and religion also affect this behavior, but their influences were found to be greatest where economic pressures are weakest, i. e., in families of high economic status. In comparison with German farmers, Scandinavians have the greater occupational mobility and the greater increase in the same; and in comparison with Lutheran farm-

ers, Catholics have the greater occupational mobility and increase in the same. Thus it seems that the German-Lutheran-high economic status combination is most favorable to the retention of farming as a family occupation. There was found to be a negative relationship between size of family and occupational mobility, a fact which taken along with the observation that Catholic families are disproportionately large may help explain the higher occupational mobility among Catholics. Factor comparisons based upon territorial mobility resulted in essentially the same generalizations as those for occupational mobility given above."

Migrants from rural South Dakota families: Their geographical and occupational distribution, W. L. SLOCUM (*South Dakota Sta. Bul. 359 (1942), pp. 20, figs. 6*).—This report presents a graphic picture of the main currents of geographical migration and of the patterns of occupational choice. "Prior to 1936 the pattern of geographical migration was mainly that of short-range movement. More migrant sons stayed in the home county than left it, and more than 6 out of 10 of both sexes stayed within the borders of the State of South Dakota. For those who left the State, the west coast, especially California, seemed to be peculiarly attractive; all but a few avoided the southern and far eastern States. . . .

"With the advent of defense work and of war major changes have taken place in the patterns of migration and occupational choice. The traditional pattern of short range migration has been altered for girls and boys alike, but especially for boys. Instead of emphasis upon short range movement the current emphasis is upon long range migration, especially to California. Likewise the movement of young men into agriculture has almost ceased. Defense work and service in the armed forces now takes boys leaving parental homes."

The Riner Community, an area of population flow, C. G. BURR and L. E. MOSELEY (*Virginia Sta., Rural Sociol. Rpt. 21 (1942), pp. [6]+24, figs. 4*).—This is the fourth in a series of community studies (E. S. R., 68, p. 120; 70, p. 556; 74, p. 564). The point most stressed in this study is the high degree of population turnover in the Riner community, i. e., the constant population flow through the community from adjacent areas of population pressure.

Boom migration: Incidence and aftermath, R. T. McMILLAN. (Okla. A. and M. Col.). (*Rural Sociol., 7 (1942), No. 2, pp. 145-155; Span. abs., p. 145*).—"It is estimated that 3.5 million civilians have migrated as a result of employment opportunities and increased wages in nonagricultural industries. The defense boom is primarily industrial, with the heaviest population movement recurring within and between cities, followed in order by withdrawals from rural-nonfarm and rural-farm aggregates. Defense migration is selective of white, single men under 30 yr. of age. Generally, migrant families are smaller than the average. Occupationally, skilled and semiskilled workers are in greatest demand. Uncertainty of the future, increased living costs, and high taxes seem to discourage savings among defense-boom workers. To counteract some of the effects of vast unemployment, relatively low wages, and undesirable levels of living anticipated in the post-war period, strongly centralized governmental control over the economic structure appears imminent. The measures utilized may afford greater protection to the socioeconomic status of large capitalists and public officials than to that of small-property holders, salaried employees, and wage earners."

The influence of tenure status upon rural life in eastern South Dakota, W. L. SLOCUM (*South Dakota Sta. Cir. 39 (1942), pp. 20, figs. 6*).—"The evidence of this study suggests that . . . families that own their farms and their equipment free of encumbrance take better care of their property than do other

types of operators; they also tend to be more neighborly, and more of them support the church. They do not, however, participate in the programs of organized groups to any large extent."

The role of rural society in the production of workers and soldiers, W. S. THOMPSON (*Rural Sociol.*, 7 (1942), No. 2, pp. 127-133; *Span. abs.*, p. 127).—"The role of rural society in providing the Nation with soldiers and workers is not adequately measured by the number of persons going directly from rural communities into these tasks. . . . Because of the declining birth rate and the stationary rural farm population this group will in the future contribute a smaller proportion of soldiers and workers to the Nation than in the recent past in spite of the fact that its birth rate remains considerably higher than that of the urban population. . . . Because of the declining proportion of farm population and the declining birth rate, we shall also have a smaller total of soldiers and workers in the prime of life 25 yr. hence than we now have."

Louisiana farm laborers and total war, H. HOFFSOMMER and R. J. RAMSEY. (Coop. U. S. D. A.). (*Louisiana Sta. Bul.* 346 (1942), pp. 18, figs. 4).—A total of 564,000 persons over 14 yr. of age were enumerated in the census of April 1940 as living on farms in Louisiana, of whom 290,000 were capable of full-time work. "When the estimated loss of labor to the armed forces and industry is accounted for, the labor force remaining on farms in 1942 will be approximately 165,000 men and 35,000 women, or a total of 200,000. Since most of those leaving the farm are from 18 to 35 yr. of age, those remaining will not be capable of doing as much work as those leaving the farm." The conclusions are reached that "the solution must be a more intensive use of the normal labor force remaining" and, "under extreme conditions, all available able-bodied town and city dwellers will be needed for a short harvest season."

The role of the village in American rural society, T. L. SMITH. (La. State Univ.). (*Rural Sociol.*, 7 (1942), No. 1, pp. 10-21; *Span. abs.*, p. 10).—"As a center of trade and commerce the village has long played a vital role in American rural society. Its function as a trade center continues to wax in importance, and at the same time the village is rapidly coming into its own as the center of the emerging rural community. Exact data concerning the number, distribution, and population of American villages are not to be had. The census includes in its tabulations only incorporated villages, numbering 10,436 in 1940, and gives very scanty information for these. A method for estimating the population of unincorporated villages from a knowledge of the number of business firms doing business in them is described, and the number of such places estimated to be approximately 7,500. The total population of villages of all types is estimated at 14,500,000. In addition to its roles as a center of trade and commerce and as the nucleus of the emerging rural community, other functions of the village are analyzed. The village serves as a place of residence for disproportionately large numbers of some of the most dependent groups in American society and particularly for aged persons of both sexes and for widowed and divorced females. The village is also the arena in which rural and urban attitudes and patterns of living collide with one another."

The local community and social control, C. R. HOFFER. (Mich. State Col.). (*Rural Sociol.*, 7 (1942), No. 1, pp. 81-84).—"The author examines the hypothesis that "the local community has an important influence in social control, notwithstanding the fact that within recent years numerous social changes suggest a different conclusion."

Patterns of crime in a rural South Dakota County, J. USEEM and M. WALDNER (*Rural Sociol.*, 7 (1942), No. 2, pp. 175-185; *Span. abs.*, p. 175).—"In a rural area, relatively untouched by urbanization, a survey of offenders during

the past 50 yr. reveals delinquency is growing in excess of population increase. There is a high incidence of criminality among town people, certain ethnic groupings, the divorced and unmarried, and the young. These are reflections of the roles which members of these strata occupy in the local social order. Communities have little insight into the factors producing criminality, and regard each delinquent as a case of personal demoralization. The administration of justice is attuned to punishment rather than to prevention or rehabilitation. Crime in a rural society requires analysis in the context of rural life rather than merely through comparison with urban patterns."

Rural public assistance and national defense, J. C. BROWN (*Rural Sociol.*, 7 (1942), No. 2, pp. 133-145; *Span. abs.*, p. 133).—"The effect of the defense program on rural public assistance is most apparent in rural 'defense areas,' in the neighborhood of army stations, naval shore and coast guard establishments, and new defense industrial plants. Reports from such areas in 20 States indicate that the situation of relief recipients and low-income families is aggravated by the increased cost of living, that the composition of part of the relief load is being modified without a reduction of the total need, and that the lack of suitable housing and sanitation, the increase in migration, and juvenile delinquency have created serious social and health problems. Federal leadership and funds are badly needed, as well as additional professional personnel to assist State and local public welfare agencies in handling these problems which so acutely affect family life and child welfare."

The Farm Security Administration and its attack on rural poverty, J. J. KING. (U. S. D. A.). (*Rural Sociol.*, 7 (1942), No. 2, pp. 155-161; *Span. abs.*, p. 156).—"The practical technics of action are premised on the initial assumption that low-income farm families, if provided with sound economic and social opportunities, will democratically grasp these opportunities and improve their conditions. The technics are: The rural rehabilitative loan with supervised guidance in home and farm management; the tenure improvement program; the water facilities work; the farm debt adjustment activity; the community and cooperative services, permitting small-scale operators to compete with large, corporate producers; the tenant purchase program; the migratory labor camps; the medical services; the cash grant aids; and others. All these technics are being integrated into one concentrated drive on mental and physical rural poverty."

Farmers, attitudes to farm programs, D. R. JENKINS. (Clemson Agr. Col.). (*Rural Sociol.*, 7 (1942), No. 2, pp. 185-193, fig. 1; *Span. abs.*, p. 185).—"In a further discussion of the survey noted (E. S. R., 87, p. 301), it is noted that "clusters of individuals reacted in a similar manner to certain groups of questions. For example, one cluster strongly favored youth programs, old-age assistance, and land-use planning but was neutral toward live-at-home programs. Another cluster strongly opposed all programs except cover crops and conservation payments, and so on. A statistical technic is applied here to identify the patterns of response in detail. Background traits that explain the cluster blocs are examined."

FOODS—HUMAN NUTRITION

[Food and nutrition studies at the Idaho Station] (*Idaho Sta. Bul.* 244 (1942), pp. 8-9, 42-43).—This progress report (E. S. R., 85, p. 855) summarizes work on drip and evaporation losses of frozen steaks, by D. E. Brady, P. Freil, and C. W. Hickman (pp. 8-9); studies on the value of the protein of field peas, by E. Woods, W. M. Beeson, J. W. Pence, and D. W. Bolin (pp. 42-43); and studies in extension of earlier work on the ascorbic acid metabolism of young men and the vitamin B complex factors in Russet Burbank potatoes, both by Woods (p. 43).

[Food studies by the Indiana Station] (*Indiana Sta. Rpt. 1941*, pp. 77-78).—This progress report (E. S. R., 83, p. 121) summarizes an extension of studies on the palatability, cooking losses, and tenderness of frozen pork and preliminary work on frozen beef, both by R. Jordan and O. D. Milligan.

Food values in shares and weights, C. M. TAYLOR (*New York: Macmillan Co., 1942*, pp. XI+92, figs. [11]).—This book presents data on the calories, protein, calcium, iron, vitamin A, thiamin, ascorbic acid, and riboflavin in serving portions, defined by weight and measure, of approximately 500 common foods and prepared dishes. The values are tabulated in terms of shares and again in terms of weight. The share system is explained. The measures, weights, and calorie values of many of the recipes are taken from Food Values of Recipes in Shares and Vitamin Units, by M. S. Rose and C. M. Taylor, a booklet which the present publication replaces. The protein, mineral, and vitamin values have been recalculated on the basis of more recent data on food composition, and the share values are based on the new dietary allowances.

Some nutritional values of common foods [and] nutritional requirements of individuals (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 2, pp. 14-16).—Tabular material is given on the values of selected foods grouped as animal products, cereals and nuts, fruits, vegetables, and sugar in terms of the calorie values and quantities of various nutrients, including proteins, vitamin A, thiamin, ascorbic acid, riboflavin, calcium, phosphorus, and iron present in average servings; and on the nutritive requirements of individuals of different ages in terms of the daily allowances for specific nutrients recommended by the committee of food and nutrition of the National Research Council.

Sorghum and sugarcane sirups increase in importance as good substitutes for sugar, O. SHEETS (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 5, p. 2).—These sirups, although not as sweet as cane or beet sugar, offer the advantage of being comparatively cheap and easily prepared in the southern farm household. They are good energy foods and are superior to sugar in nutritive value in that they contain the essential minerals Ca, P, Fe, and Cu.

Edible soybeans, W. C. SHERMAN and H. R. ALBRECHT (*Alabama Sta. Bul.* 255 (1942), pp. 16).—Since soybeans are successfully grown in the South and offer definite possibilities of improving the protein, mineral, and vitamin content of southern diets, experiments were conducted to determine what varieties of edible soybeans are best adapted to culture in Alabama. Data are reported on yields, the date of maturity, seed characteristics, and cooking quality of mature soybeans of early, late, and midseason varieties grown in these experiments. From results with the green shelled soybeans, also included in the test, it is concluded that green vegetable soybeans for table use from mid-July to late September or early October will be assured by selection of one or more varieties in each of the following groups: Early—Willomi, Imperial, or Emperor; midseason—Funk Delicious, Hokkaido, or No. 85550; and late—Rokusun, Tokio, No. 93057, Delsta, or Delnoshat. The nutritive value of soybeans is considered, particularly in comparison with that of cowpeas and other beans and peas. Recommendations for growing edible soybeans and the methods of preparing them for table use are also given.

Arsenic in fresh-water fish, M. M. ELLIS, B. A. WESTFALL, and M. D. ELLIS. (Univ. Mo. et al.). (*Indus. and Engin. Chem.*, 33 (1941), No. 10, pp. 1331-1332).—The arsenic content of 15 species of fresh-water fish, determined by analysis of 681 fish from 15 inland waters in Florida, Georgia, Alabama, and Texas, was found to average about 0.75 p. p. m. as As_2O_3 on the basis of total wet weight, or 3.54 p. p. m. on the basis of total dry weight. This content, it is pointed out, is considerably lower than that reported for marine fish. Figures on the total

wet basis are representative of the arsenic content of fish meals. The eviscerated portion representing the part usually consumed as food was analyzed separately for 156 of the fish, including bass, buffalo, carp, suckers, sunfish, and five other species. Average and maximum values obtained for these were 0.48 and 2.55 p. p. m. on the wet basis and 1.85 and 11.89 p. p. m. on the dry basis. Total oil obtained as the ether extract of the whole fish averaged 11.80 p. p. m. of arsenic (As_2O_3) and ranged as high as 160.71 p. p. m. This oil, constituting only 2.49 percent of the total wet weight, carried 22.8 percent of the total arsenic of the fish. Fourteen visibly fat, large-mouthed black bass in which the liver masses were assayed separately showed the total oil (constituting 5 percent of the weight of the fish) to contain on an average 3.13 p. p. m. of arsenic; the body oil 2.29 p. p. m.; the oil from viscera without liver 4.37 p. p. m.; and the liver oil 40.51 p. p. m. In view of the findings it is considered that fresh-water fish, and particularly their livers and oils, must be regarded as potential sources of arsenic in foods and other commercial products utilizing fresh-water material.

Mold inhibitors for food products, H. MACY. (Univ. Minn.). (*Assoc. Food and Drug Off. U. S., Quart. Bul.*, 6 (1942), No. 1, pp. 9-12).—This paper, presented as an address, reviews briefly significant research contributions concerning mycostatic and fungistatic agents applicable to foods as mold inhibitors. It is indicated that of the various chemical compounds or methods suggested for inhibiting mold growth on foodstuffs none to date have proved as unobjectionable as the sodium or calcium propionates.

Preservation of victory foods a farm home goal, E. A. CURREY (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 5, p. 1).—Canning, possibly at community canning centers; freezing and frozen storage at freezing plants; sun-drying; and storage in ventilated pantry, storage basement, or outdoor cellar or storehouse are noted as methods available for preservation of fruits and vegetables grown in Mississippi home and victory gardens.

Preparing fruits and vegetables for refrigerated locker storage (*Oklahoma Sta. Misc. Pub.* 7 (1942), pp. 6).—Products desirable to conserve under Oklahoma conditions, selection of varieties desirable from the standpoint of quality and production, and selection of suitable containers are discussed in general terms; and specific directions are given for individual fruits and vegetables with regard to handling and preparation for freezing.

Drying fruits and vegetables for home use, A. L. STARK and E. MILLER (*Farm and Home Sci. [Utah Sta.]*, 3 (1942), No. 2, pp. 3, 10-11, figs. 3).—General information is given concerning temperature, air movement, and the sulfuring process applied in the drying procedure. Practical directions for drying individual fruits and vegetables under Utah conditions cover such points as satisfactory stage of maturity, preparation for drying, sulfuring (when applied), and drying times and conditions.

Medical evaluation of nutritional status, II-VI. (Cornell Univ. et al.). (*Milbank Mem. Fund Quart.*, 18 (1940), No. 4, pp. 403-424, figs. 4; 19 (1941), Nos. 1, pp. 45-71, figs. 6; 3, pp. 207-240, pls. 2; pp. 241-251; pp. 252-281, figs. 9).—This continues the series (E. S. R., 84, p. 842).

II. Measurement of visual dark adaptation with the adaptometer, E. P. HUNT and C. E. PALMER.—The Hecht-Shlaer adaptometer is subjected to critical examination as to the uniformity of results obtained with three different instruments of the same type and the errors of measurement as determined by repeated tests with one instrument on the same individual. Certain suggestions are given for modifications and extensions of the original specifications, and the results of the study of errors of measurement are summarized as follows:

"Variation in the subjective criteria of perceptible light flashes may be of sufficient magnitude to account for a considerable proportion of the variation among different individuals in final threshold values obtained after 30 min. of dark adaptation. Study of duplicate adaptometer tests indicates that there is a marked difference in the reliability of threshold measurements for different periods during dark adaptation. The variability of duplicate tests increases rapidly from 30 sec. to a maximum at 9.5 min. and thereafter declines to a minimum of ± 0.09 log unit after 30 min. of dark adaptation."

III. *Hemoglobin and erythrocyte values for adolescents in high-income families*, D. G. Wiehl.—A detailed study was made of hemoglobin and erythrocyte values in 155 boys between 12 and 18 yr. of age and 140 girls between 12 and 17 yr. These children, selected as being without apparent infection, disease, or nutritional deficiency, were all attending a private school in New York City and were mostly from Jewish families. In the girls, the change from childhood levels apparently began before the age of 12 yr. In the 12- to 17-yr. age period observed it was found that hemoglobin in the whole blood was about the same at every age, averages at the specific ages varying from 13.9 to 13.7 gm. per 100 cc.; that the number of red cells per cubic millimeter of blood decreased with age from 5.4 to 5.1 millions; that mean red cell volume increased from $82.1\mu^3$ at 12 yr. to $87.8\mu^3$ at 16-17 yr. combined; that hemoglobin content per cell increased slightly with age from 26.0 to $27.2\mu\text{g.}$; and that the concentration of hemoglobin in the red cells varied significantly at these ages. With the boys, hemoglobin in whole blood increased from 13.6 gm. per 100 cc. at 12 yr. to 15.3 gm. at 17-18 yr., most of the increase coming at 13 and 14 yr.; the number of red cells increased at 13 yr. and then decreased to a fairly constant count of about 5.7 millions; the mean red cell volume increased from $70.6\mu^3$ at 13 yr. to $85.6\mu^3$ at 15 yr. and to $87.7\mu^3$ at 17-18 yr. The marked changes observed in this detailed study of adolescents indicated that in any study of a comparable group the results must be evaluated on the basis of standards according to sex and year of age.

IV. *The ocular manifestations of avitaminosis A, with especial consideration of the detection of early changes by biomicroscopy*, H. D. Kruse.—This is a preliminary report on the biomicroscopic examination of the conjunctiva as a means of detecting early vitamin A deficiency and of determining the requirements of this vitamin. Of a group of 166 adults, including both white and Negro, in a low-income group 65 showed gross ocular manifestations of vitamin A deficiency in the form of one or more characteristic raised spots known as Bitot's spots. These are described in some detail, with colored photographs illustrating lesions of varying degree. Among 143 subjects who were given, in addition to the gross examination, a microscopic examination under slit-lamp illumination, 45 percent showed gross and 54 percent microscopic ocular lesions. The latter are described and differentiated from those of riboflavin deficiency. In addition to further characterization of the spots, the biomicroscope reveals changes in the degree of light transmission of the conjunctiva, with transparency, translucency, and opacity representing progressively advancing stages.

Following continuous vitamin A therapy in daily doses of 100,000 International Units of a part of the group, the conjunctival lesions of 9 subjects disappeared entirely in from 6 to 8 mo. In all the others marked improvement "to the point of near disappearance" took place, while a control group not receiving therapy showed no improvement.

The report includes a lengthy review of the literature on the ocular manifestations of vitamin A deficiency with particular reference to the relative time of appearance of xerosis conjunctivae and night blindness, with the conclusion that xerosis probably precedes night blindness as an early sign of avitaminosis A.

V. *Prevalence of deficiency diseases in their subclinical stages*, D. G. Wiehl and H. D. Kruse.—Data from the survey described in the first report of the series were used in the estimation of the relative prevalence of mild cases of vitamin A, riboflavin, and vitamin C deficiency and nutritional anemia in three groups—(1) high school students in the group of relatively high income (not tested for vitamin A), (2) high school students of the low-income group, and (3) W. P. A. employees, all in New York City. The diagnoses of vitamin A deficiency and ariboflavinosis were based on examination with the biomicroscope under slit-lamp illumination, as noted above for vitamin A and by Kruse et al. (*E. S. R.*, 84, p. 707) for riboflavin, hemoglobin by colorimetric determination of oxyhemoglobin with the Evelyn photoelectric colorimeter, and plasma ascorbic acid by the photoelectric colorimetric procedure of Mindlin and Butler (*E. S. R.*, 80, p. 728).

In (1) few of the subjects showed a deficiency of ascorbic acid, iron, or riboflavin, and in no case was there multiple deficiency. Among the boys the only significantly low values were for ascorbic acid, with values less than 0.6 mg. per 100 cc. in 6.7 percent. Among the girls hemoglobin values less than 12 gm. per 100 cc. were found in 3.1 percent, mild riboflavin deficiency in 4.7 percent, and low ascorbic acid values in 4.2 percent of the group. In (2) 86.6 percent of the children showed some stage of vitamin A deficiency, 75.8 percent mild ariboflavinosis, 49.9 percent low plasma ascorbic acid values, and 3.3 percent hemoglobin values below the assigned minimum. Boys showed relatively advanced stages of these deficiencies to a greater extent, with the exception of iron, than the girls. Many had multiple deficiencies. In (3) all but one showed some stage of vitamin A deficiency, with 45.5 percent of the group showing the more advanced or spot changes. These were much more prevalent among the men than the women. Riboflavin deficiency was evident in 38.4 percent of the subjects, with no significant differences between the men and the women. Low plasma ascorbic acid levels were found in 55.2 percent and hemoglobin levels below the standard in 6.8 percent of the women and 7.6 percent of the men.

VI. *Dark adaptation of high school children at different income levels*, E. P. Hunt.—High school students from the groups represented in the cooperative investigation, selected as being in good health and willing to participate in the study, served as subjects. The dark-adaptation tests were made with a Hecht-Schlaer adaptometer, and preceding the test each subject was given a physical examination, including observations on the condition of the eyes and the Snellen visual acuity test. Diet histories were obtained for the 2-day period immediately preceding the adaptation test, and anthropometric measurements were taken either on the day of the test or 1 or 2 days later. The data, subjected to extensive statistical treatment, are summarized essentially as follows:

The mean threshold after 20 min. for 131 of the low-income group was 2.765 log units with a variability of ± 0.516 log unit, and for 136 children in the high-income group 2.540 log units with a variability of ± 0.330 log unit. The mean threshold level at this time was not affected in either income group by age; sex; visual acuity; pigmentation of the iris; hour of the test; time of color change from purple, violet, or blue to gray or white; or phase of the menstrual cycle. The mean threshold level at 30 min. for 175 cases of the high-income group was 2.463 log units with a variability of ± 0.154 log unit. In the low-income group 78 percent and in the high-income group 44 percent of the diets provided less than 5,000 International Units of vitamin A daily.

Appraisal of nutritional status (*Amer. Jour. Pub. Health*, 31 (1941), No. 10, pp. 1061-1082, figs. 7).—This report of a symposium held at the 1940 meeting of the American Public Health Association consists of Introductory Remarks, by F. G. Boudreau (pp. 1061-1062) and the following papers on different phases

of the cooperative nutritional status investigation noted above: Dark Adaptation Characteristics of Private School Children Measured With the Adaptometer, by C. E. Palmer (pp. 1063-1067); Medical Evaluation of Nutritional Status—Roentgen Appraisal of Development, by W. M. Schmidt (pp. 1068-1072); Selecting Cases of Anemia Among Adolescents, by D. G. Wiehl (pp. 1073-1078); and Chemical Methods for Determining the Plasma Level of Vitamin C, by H. D. Kruse (pp. 1079-1082).

Effect of various dietary supplements on growth and lactation in the albino mouse, Z. B. BALL and R. H. BARNES. (Univ. Minn.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 3, pp. 692-696).—The basal diet in the experiment reported consisted of glucose, casein, lard, yeast, and salt mixture. Young mice on this diet with no supplements grew at a better rate than others on a commercial food mixture (Purina Fox Chow) alone or supplemented with lettuce and a dried brewers' yeast. Ascorbic acid had no effect on the food intake or growth. Lactation was unsatisfactory. The addition of ascorbic acid or liver extract alone did not increase the survival period of the young through the suckling period, but dehydrated grass and wheat bran improved the lactation and there was evidence that the effects were additive, as was also the case with ascorbic acid and wheat bran. Supplementing the wheat bran with inositol or phytin not only was without beneficial effect but appeared to have a deleterious effect. It is concluded that the lactation-promoting effect of the dehydrated grass and wheat bran is not due to an increase of thiamin, riboflavin, pantothenic acid, factor W, or inositol in the diet.

Cucurbit seed globulins.—I, Amino acid composition and preliminary tests of nutritive value, H. B. VICKERY, E. L. SMITH, R. B. HUBBELL, and L. S. NOLAN. (Conn. [New Haven] Expt. Sta.). (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 613-624).—As noted in a preliminary report (E. S. R., 85, p. 270), globulins from cucurbit seeds were prepared as possible substitutes for edestin, now scarcely available. The method of preparation consisted of extracting the ground, air-dried, nondefatted seeds with warm 10 percent NaCl, heating the turbid extract to 75° [C.] to effect coagulation of minor quantities of the proteins, presumably of the albumin type, and of siphoning the aqueous phase from under the fat emulsion which separated upon cooling and standing. The aqueous phase thus obtained was filtered through a thick layer of paper pulp, centrifuged, and refiltered, and the globulin was precipitated by treatment of the filtrate, heated to 60°, with 4 volumes of water also at 60°, and allowed to stand overnight in the cold. The precipitate obtained was recrystallized and washed by suspension in 30 percent alcohol and finally with 95 percent alcohol on the funnel. By this method yields of from 6.2 to 15.4 percent, on the basis of air-dried, whole seeds, were obtained from seed of the various species of Cucurbitaceae. Low ash values indicated a high degree of purity of the preparations with respect to inorganic contamination. The crystalline globulins from the squash and the pumpkin seeds were indistinguishable on the basis of yields of arginine, tyrosine, and tryptophan, but these three globulins did differ on this basis from those from watermelon, cantaloup, and cucumber seeds. The watermelon seed globulin yielded 17.9 percent arginine, this being a higher proportion than from any other vegetable protein on record. Feeding tests with rats receiving hemp seed edestin or the globulin of *Ocurebita moschata* as the sole source of protein in an adequate diet showed these to have about equal nutritive value. Neither was as satisfactory as casein or lactalbumin in producing rapid growth. Watermelon seed globulin was less satisfactory than that of squash seed as the sole source of protein for young animals.

The synthesis of cystine in vivo, W. C. ROSE and T. R. WOOD. (Univ. Ill.). (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 381-389).—Young rats were fed a

basal diet in which the nitrogenous components were supplied in the form of a mixture of amino acids devoid of cystine and methionine and in which other dietary factors were adequate. In experimental ad libitum feeding experiments of 36 or 48 days, the rats received this basal diet supplemented (1) with cystine and methionine or (2) with methionine alone. At the end of the feeding tests the animals were killed and analyzed in toto to determine the gain in tissue cystine over the content at the beginning of the tests, as determined by analysis of control rats killed at that time. The results showed that as much as from 4 to 6 mg. of cystine had been synthesized daily for purposes of growth. No significant differences were observed in the cystine increases in the tissues or in the rates of gain in body weight of animals receiving (1) methionine alone, and (2) methionine plus cystine. The 4-6 mg. appeared thus to represent a close approximation of the cystine requirement of the young growing rat for new tissue formation. Since in certain of the experiments methionine was the only organic sulfur compound available in sufficient proportions to account for the cystine deposition in the tissues, it is concluded that the sulfur of methionine was utilized in the manufacture of cystine.

The utilization of the methyl group of methionine in the biological synthesis of choline and creatine, V. DU VIGNEAUD, M. COHN, J. P. CHANDLER, J. R. SCHENCK, and S. SIMMONDS. (Cornell Univ.). (*Jour. Biol. Chem.*, 140 (1941), No. 2, pp. 625-641, fig. 1).—The experiments here described were devised to test the previously suggested theory (E. S. R., 84, p. 274) that methionine in the diet might serve as a source of methyl groups in the metabolic elaboration of choline. Rats were fed methionine containing a deuteriomethyl group, and the transfer of these labeled methyl groups was demonstrated by the isolation of deuteriocholine and deuteriocreatine from the tissues and of deuteriocreatinine from the urine. All the deuterium of the isolated choline was shown to be in the methyl groups. After a feeding period of 14 weeks, the methyl groups of the isolated choline, creatine, and creatinine contained 85 percent of the deuterium in the deuteriomethionine fed, thus indicating that the latter substance was the sole precursor of the methyl groups in the diet fed. The transfer of methyl groups from choline to creatine was also demonstrated by the isolation of deuteriocreatine from the tissues and deuteriocreatinine from the urine of rats fed deuteriocholine and homocystine. It is suggested that this ability of choline and methionine to furnish a labile dietary supply of methyl groups explains the action of these compounds in the prevention of fatty infiltration of the liver and hemorrhagic kidneys. "The data support the hypothesis that the body is incapable of generating methyl groups for certain methylations and that methyl groups must be supplied in the diet in a biologically labile form such as occurs in methionine and choline."

The partial replacement of dietary methionine by cystine for purposes of growth, M. WOMACK and W. C. ROSE. (Univ. Ill.). (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 375-379, fig. 1).—Growth response of young rats fed diets containing varying proportions of cystine and methionine, but otherwise adequate, indicated that cystine is capable of stimulating growth only when methionine is furnished in suboptimal amounts.

Absence of supplementary relationships in requirements for pyridoxin and essential fatty acids, G. A. EMERSON. (Univ. Calif.). (*Soc. Exptl. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 445-448).—The possible sparing action of linoleic acid on the pyridoxin requirement or of pyridoxin on the linoleic acid requirement of rats was tested by the feeding of three levels (20, 40, and 80 mg.) of ethyl linoleate in conjunction with two levels (5 and 15 μ g.) of pyridoxin as supplements to a diet of extracted casein 24, sucrose 72, and salt mixture (Mc-

Collum 185) 4 parts, supplemented six times weekly by crystalline thiamin 15, riboflavin 20, and carotene 80 μ g., liver filtrate equivalent to 5 gm. fresh liver, calciferol 12 International Units, and α -tocopherol 0.5 mg. The carotene, calciferol, and α -tocopherol were each fed in 2 drops of ethyl laurate.

The rats on the fatty acid-deficient diet showed the characteristic symptoms and signs of this deficiency. Complete protection against the dermatitis was secured with the smallest (20 mg.) dosage of ethyl linoleate, but growth was stimulated to a greater extent on the larger amounts. Rats on the highest dosage of ethyl linoleate but with no pyridoxin showed the typical acrodynia of pyridoxin deficiency. The dermatitis was partially but not completely prevented by 5 μ g. of pyridoxin. Little difference was apparent between the animals receiving the different levels of ethyl linoleate. Growth was limited by the amount of pyridoxin.

It is concluded that the two deficiencies are entirely independent of each other and that the types of dermatitis produced are easily distinguishable.

The dipeptidases of intestinal mucosa, F. B. GAILEY and M. J. JOHNSON. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 141 (1941), No. 3, pp. 921-929).—The crude enzyme used in this study represented a glycerol extract of hog intestinal mucosa obtained by mixing equal volumes of fresh mucosa and pure glycerol at the packing plant; by storing at -8° [C.] for about 10 days, in which time maximum activity was attained and found to be retained even after 50 days; and finally, by centrifuging to remove insoluble cellular material. The extent of hydrolysis of peptides was determined by the acetone-HCl titration method of Linderström-Lang. Largely because of the instability of the dipeptidases in hog mucosa, it was impossible to obtain one or more of them in a state of enzymatic homogeneity. Information was obtained, however, concerning the nature and activation behavior of three dipeptidases of erepsin. An alanyl-glycine-splitting enzyme was not activated by Co^{++} , Mn^{++} , or cysteine, or combinations of these; an enzyme hydrolyzing diglycine rapidly was activated somewhat by Mn^{++} but best by Co^{++} ; and an enzyme hydrolyzing prolylglycine and probably other dipeptides not having an amino group in the *l* configuration was activated by Mn^{++} . Leucylpeptidase was found to be responsible for most of the peptidase activity of dried intestinal mucosa. There was no evidence for the existence of a specific prolinase attacking all propyl peptides.

The coenzyme I content of rat tissues in experimental hyperthyroidism, E. KATZENELBOGEN, A. E. AXELROD, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 141 (1941), No. 2, pp. 611-617).—The coenzyme I content of the tissues was determined by the yeast fermentation method of Axelrod and Elvehjem (*E. S. R.*, 82, p. 727). As compared with normal controls the hyperthyroid rats, fed a ration low in nicotinic acid, showed marked decreases in the coenzyme I content of the tissues; these decreases amounted to as much as 50 and 37 percent in liver and kidney cortex, respectively, when the ration contained no added nicotinic acid. When the nicotinic acid content of the ration was increased to 20 mg. per 100 gm., the coenzyme I content of the tissues of the hyperthyroid rats remained normal. The addition of nicotinic acid did not increase the growth rates of either the control or the hyperthyroid rats.

One hundred studies of the calcium, phosphorus, iron, and nitrogen metabolism and requirement of young women, R. M. LEVERTON, and A. G. MANN. (*Nebraska Sta. Res. Bul.* 125 (1942), pp. 39, figs. 6).—This study was carried out over a 3-yr. period as part of the regional project of the North Central States relating to the nutritional status of college women. Ca, P, Fe, and N metabolism tests of 7 days' duration were conducted, by procedures fully

outlined, on 70 healthy college women between the ages of 18 and 27 yr. living on their customary freely chosen diets. Fifty-three of the individuals were studied once, 7 twice, 7 three times, and 3 four times, making a total of 100 tests. The results, presented and discussed in detail, showed that in the case of each of these elements the lowest retention or the largest negative balance occurred on the lowest intake, and as the intakes rose the negative balances decreased and finally disappeared and the size of the retentions increased. The average daily intakes and the retentions of each of the four elements showed appreciable variations in the 100 tests, averaging, respectively, as follows: Ca, 0.857 (intake) and 0.013 gm. (retention); P, 1.088 and 0.033 gm.; Fe, 10.44 and 1.37 mg.; and N, 9.46 and 0.58 gm. In the 17 individuals, each studied from two to four times, the variations shown by a subject between successive tests were less than the variations between individuals. It was not possible to demonstrate that body size had any effect on metabolism or requirement. On the basis of the percentage of each nutrient retained at different levels of intake, the following recommendations for the "minimum requirement" and the "optimal allowance," respectively, are given: Ca, 0.83 and 1.08 gm.; P, 1.06 and 1.43 gm.; N, 8.15 and 11.34 gm.; and protein (calculated from N), 50.94 and 70.87 gm.

The results of the iron metabolism studies of these young women bear out the earlier conclusion (E. S. R., 86, p. 419) "that if the diet is generous in essential nutrients, other than iron, which have been shown to promote efficient iron absorption and utilization, there will be a sufficient amount of iron to meet daily needs and to replace that lost during menstruation even at as low a level of intake as 7.21 mg. daily."

The iron metabolism and requirement of young women, R. M. LEVERTON and A. G. MARSH. (Nebr. Expt. Sta.). (*Jour. Nutr.*, 23 (1942), No. 3, pp. 229-238).—This is a separate publication of the results of the studies of the Fe metabolism included in the study noted above.

Studies in mineral metabolism with the aid of artificial radioactive isotopes.—VI, Cobalt, D. H. COFF and D. M. GREENBERG. (Univ. Calif.). (*Natl. Acad. Sci. Proc.*, 27 (1941), No. 3, pp. 153-157, fig. 1).—This study is one in the series noted previously (E. S. R., 84, p. 554). Radioactive cobalt, Co^{60} , prepared by bombardment of iron with deuterons was made up, after purification and determination by procedures noted, as a cobalt chloride solution containing 0.1 mg. of cobalt per cubic centimeter. Two 250-gm. male rats were each given 10 μg . of the radioactive cobalt, one by intraperitoneal injection, the other by stomach tube. The animals were then placed on the stock diet, urine and feces were collected separately at regular intervals, and after 96 hr. the animals were sacrificed and the blood, muscle, bone, and various organs were analyzed for their content of radioactive cobalt. The results indicated that 70 percent of the cobalt was eliminated within the first 10 hr. and 90 percent within 2 days. The urine was the chief path of excretion of the injected cobalt, although there was a small but continuous elimination in the feces. About 60 percent of the cobalt given by stomach tube was recovered in the feces, and most of the 40 percent absorbed was rapidly excreted in the urine. Even with the small dose administered less than 5 percent was recovered in the body after 4 days. Spleen, pancreas, kidney, and liver showed relatively high concentrations (5.60, 2.50, 1.89, and 0.67 μg . per 100 gm. dry weight) and bone contained 0.42 μg . per 100 gm. dry weight. It is suggested that the concentration in bone may have some bearing on the polycythemic effect of cobalt, but that the requirement of the tissues for cobalt, if any, must be very small.

The retention and elimination of fluorine in bones, G. E. GLOCK, F. LOWATER, and M. M. MURRAY (*Biochem. Jour.*, 35 (1941), No. 10-11, pp. 1235-1239,

fig. 1).—Fluorine was determined spectrographically and chemically in human rib bones obtained as autopsy material from subjects dying at different ages from various causes but with no obvious signs of fluorosis. In general the fluorine content of the bones increased with increase of age. The lowest value was 0.02 percent and the highest 0.3 percent. Rats fed small amounts of fluorine from the age of 6 weeks for periods up to 84 weeks showed the concentration in the long bones to increase with age. The uptake was at first rapid and then more gradual, the increase with age apparently following a logarithmic curve. The bones of the fluorine-fed rats were unusually white, thickened, and brittle. After withdrawal of the fluorine from the diet, the elimination from the bones was the inverse of the uptake.

The absorption and excretion of 'minor' elements by man.—I, Silver, gold, lithium, boron, and vanadium, N. L. KENT and R. A. McCANCE (*Biochem. Jour.*, 35 (1941), No. 7, pp. 837-844).—The study involved spectrochemical analyses and prolonged balance experiments with patients and normal persons receiving the minerals in various ways.

"A patient with severe generalized argyria excreted less than 2 mg. of silver per week, all of it in the feces. A patient who had received 550 mg. of gold intramuscularly excreted 6.7 and 9.1 mg. in 2 successive weeks, 78 percent of it in the urine. Soluble lithium salts taken orally by normal persons were rapidly and completely excreted in the urine, but the Li in natural foods was poorly absorbed. Only 25 percent of the Li in a brown bread diet was excreted in the urine. Boron taken by mouth as boric acid was rapidly excreted in the urine. B in foods was much more readily absorbed than Li, 92 percent of it appearing in the urine. Eighty-one percent of the vanadium, which had been administered intravenously as sodium tetravanadate to normal persons in six daily doses, was excreted in the urine by the seventh day after the last injection. Nine percent was excreted in the feces in the same time."

Vitamins, A. G. HOGAN (*Missouri Sta. Bul.* 446 (1942), pp. 15).—Practical information on the chemically identified vitamins is presented in concise form. Nutrients in feedstuffs and foods are first differentiated as the "big things" and the "little things" in nutrition. A tabulation of the vitamins is given, consisting of 11 whose existence is undisputed, of which vitamin A (carotene), B₁ (thiamin), C (ascorbic acid), G (riboflavin), nicotinic acid, and D are classified as of practical importance because many foods contain insufficient amounts of them, and E, K, B₆ (pyridoxin), pantothenic acid, and biotin as of less practical importance because most foods contain adequate amounts. Choline is noted as a substance with many of the characteristics of a vitamin, but which has not been officially classified as such, and inositol and *p*-aminobenzoic acid as compounds concerning the vitamin nature of which there is some evidence, but which have not been extensively investigated. In addition it is thought that at least one and probably several vitamins are in existence but have not yet been recognized. Each of the 14 recognized vitamins is discussed as to symptoms of deficiency in various species, stability, and general destruction.

Concerning the provision of vitamins to meet human needs, the author steers a middle course between the extremes of complete indifference to their provision in the diet to undue concern that each meal should provide its mathematical quota of any vitamin. "Either extreme is to be avoided. A more reasonable attitude is to adopt a flexible but consistent daily dietary regimen that includes approved quantities of the protective foods." As for the use of pure vitamins and vitamin mixtures, it is emphasized that they "have their proper place, if taken under the guidance of a dietitian or physician. They may be helpful to many individuals with bad food habits, but they are not a

substitute for proper food, and they cannot be depended on to maintain optimum health."

Where to get the vitamins and minerals important in human nutrition, W. ARMSTRONG (*Oklahoma Sta. Cir. 100 (1942), pp. 11*).—In this nontechnical publication information on the vitamins is tabulated as to properties, functions in the body, conditions in man caused by lack of the vitamin or cured by feeding it, and best plant and animal sources. The sources are listed in decreasing importance of the food as a source of the vitamin in question as calculated from the approximate potency of an average serving. Minerals, tabulated in a similar manner, include calcium, iron, phosphorus, copper, and iodine. Information is also tabulated on conditions which may increase an individual's need for food nutrients, with checks against the separate vitamins, protein, and minerals (not differentiated).

The human excretion of carotenoids and vitamin A, G. WALD, W. R. CARROLL, and D. SCIARRA (*Science, 94 (1941), No. 2430, pp. 95-96*).—From observations reported in the literature on the relative potency of carotene and vitamin A for rats and from a series of studies here reported on human subjects with determinations of carotene, xanthophyll, and vitamin A in feces on unrestricted diets and on diets high and low in one or more of these factors, the authors suggest that "due to its low apparent absorption, carotene in human bio-assay should be at best only about 40 percent as effective as an equal weight of vitamin A, and should possess only about two-thirds the potency now assigned to it on the basis of rat assays." The report of Booher et al (*E. S. R., 83, p. 278*) is thought to afford some confirmation of this conclusion. The fact that in rats the different potencies of β -carotene and vitamin A are explained by their differential absorptions is considered to imply that following absorption they are about equally effective. On the assumption that β -carotene is converted into vitamin A in vivo by symmetrical cleavage, 1 molecule of carotene yielding 2 molecules of vitamin A, carotene and vitamin A should be about equally potent in vivo following absorption. The present experiments are considered to indicate a similar possibility in man.

Inadequacy for mice of a synthetic diet supplemented with all known vitamin B factors, E. TROESCHER-ELAM and H. M. EVANS. (*Univ. Calif. et al.*). (*Soc. Expt. Biol. and Med. Proc., 48 (1941), No. 3, pp. 549-555, fig. 1*).—Young mice on a diet containing extracted casein, sucrose, salts, cod-liver oil, corn oil, and butterfat and supplements of pure thiamin chloride, riboflavin, pyridoxin hydrochloride, nicotinic acid, calcium pantothenate, choline hydrochloride, ascorbic acid, inositol, and *p*-aminobenzoic acid grew at a good rate, but after some weeks the fur was not consistently clean. Increasing the casein and salts or doubling the quantity of vitamin supplements had no effect on growth or the condition of the fur, but growth was increased and the condition of the fur improved by feeding fresh beef liver and to a less degree by a concentrate of a liver extract, the preparation of which is described. Pimelic acid as an additional supplement was without effect.

Studies on the rat growth assay method for riboflavin, H. R. STREET (*Jour. Nutr., 22 (1941), No. 4, pp. 399-408, fig. 1*).—In the method described the B vitamins other than riboflavin are supplied by aqueous rice bran extract, which is given at standard time intervals. The riboflavin content of the materials being tested is calculated from the effective gain, this being the gain of a group receiving the unknown material minus the gain of a similar control group. The technic is described in detail, and data are given on seasonal variations in results, the validity of the procedure, and on analyses of wheat extract as a source of the B complex. With the diet and procedure as described, the relation

between the growth response, expressed as effective gain, and the dose of riboflavin is linear. The bran extract is considered preferable to the wheat extract used in the Bourquin-Sherman rat growth method, as the latter does not furnish the other B vitamins in adequate amounts.

A riboflavin excretion test as a measure of riboflavin deficiency in man, V. A. NAJJAR and L. E. HOLT, JR. (*Bul. Johns Hopkins Hosp.*, 69 (1941), No. 5, pp. 476-481).—In a volunteer subject on a riboflavin-free dietary regime for 30 days it was observed that the urinary excretion of flavin, as determined by the fluorometric method of Najar, noted on page 621, fell to zero on the sixteenth day, and despite the fact that the diet was continued without alteration for another 2 weeks, no symptoms of ariboflavinosis developed. It was considered, therefore, that the 24-hr. urinary output of riboflavin was not an accurate measure of riboflavin deficiency, since only the immediate dietary intake was reflected. A test which appeared to correlate more closely with clinical riboflavin deficiency was one employing an intravenous injection, following an overnight fast, of 1 mg. of riboflavin dissolved in distilled water. Excretion in the urine was determined for a control period of 1 hr. previous to the injection and followed for half-hourly and then hourly periods for 4 hrs. In this test a group of 10 normal subjects showed a marked excretion in the first half-hour, with a sharp decrease in the second half-hour, and an approach to the preinjection level by the end of the fourth hour; from 32 to 72 percent of the injected dose was retained in the body. In contrast the excretion of riboflavin in the urine of 4 subjects showing clinical symptoms of an induced riboflavin deficiency was strikingly less, even in the initial half-hour period, and from 81 to 93 percent of the injected dose was retained in the 4-hr. test.

The riboflavin content of cereal grains and bread and its distribution in products of wheat milling, J. S. ANDREWS, H. M. BOYD, and D. E. TERRY (*Cereal Chem.*, 19 (1942), No. 1, pp. 55-64, fig. 1).—The microbiological method employed for the assay of riboflavin (see page 621) was essentially that of Snell and Strong except that the extracts were prepared by autoclaving the samples with water and digesting the resulting suspensions with takadiastase. Values obtained for each of the six varieties of spring wheat, as grown in four different locations, showed averages by varieties to range from 1.06 to 1.32 $\mu\text{g.}$ per gram, while averages by regions ranged from 1.17 to 1.23 $\mu\text{g.}$ per gram. These results suggested differences due to variety but not to environment. In contrast, earlier tests with these same samples had shown that the thiamin content was influenced by environment, while differences between varieties were insignificant (E. S. R., 87, p. 604). Values ranging from 1.00 to 1.30 $\mu\text{g.}$ per gram and suggesting neither varietal nor environmental differences were obtained for another series of samples, including varieties of soft wheats and hard winter wheats. Analyses of several varieties each of barley, oats, rye, yellow corn, and white corn, giving respective averages of 1.21, 1.30, 1.43, 1.40, and 1.38 $\mu\text{g.}$ per gram, showed these grains to be quite similar to wheat in riboflavin content.

Values obtained from analyses of the products separated in the milling of wheat showed that about two-thirds of the total riboflavin was contained in the feeds—red dog, bran, and shorts. Patent flour (65 percent extraction) contained about 0.94 $\mu\text{g.}$ riboflavin per gram as compared with 1.00 $\mu\text{g.}$ per gram in the wheat from which it was milled. A series of breads made from patent flour, from the same supplemented with riboflavin, and from whole wheat flour showed no measurable loss of riboflavin during the process of their production, but large losses occurred when slices of bread were unduly exposed to the light. These losses in white bread (up to 50 percent) were much greater than in dark bread (up to 10 percent) and suggested the importance of carrying

out drying operations in the dark in the preparation of bread samples for analysis.

Failure to cure or prevent graying of rats with *p*-amino benzoic acid, G. A. EMERSON. (Univ. Calif.) (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 448-449).—The claim of Ansbacher (E. S. R., 86, p. 711) that graying of the fur of rats can be cured or prevented by *p*-aminobenzoic acid was tested by attempts (1) to cure by the administration of *p*-aminobenzoic acid the graying produced by a diet furnishing all of the recognized B vitamins except pantothenic acid and (2) to produce the graying by the use of the Ansbacher ration. In the first series *p*-aminobenzoic acid was without effect either as a growth stimulant or in curing the graying, while calcium pantothenate caused a marked darkening of the fur in the presence or absence of *p*-aminobenzoic acid. In the second series graying appeared in none of the animals even after 2 mo. on the diet, a time sufficient to cause graying in the absence of pantothenic acid.

Ascorbic acid content of five quick-frozen vegetables as affected by composition of cooking utensil and volume of cooking water, J. A. MCINTOSH, D. K. TRESSLER, and F. FENTON. (N. Y. State Expt. Sta.). (*Jour. Home Econ.*, 34 (1942), No. 5, pp. 314-318).—Quick-frozen brussels sprouts, cauliflower, lima beans, peas, and spinach were boiled in different amounts of water within the limits of household practice in covered and uncovered stewpans of aluminum, enamel, Pyrex, and stainless steel. Vitamin C, including ascorbic and dehydroascorbic acid, was determined by a modified Bessey and King (E. S. R., 71, p. 137) procedure in the uncooked and cooked frozen vegetables and cooking water. In these tests the composition of the cooking utensil was found to have very little effect on the ascorbic acid content of the boiled quick-frozen vegetables, and with few exceptions the retention was the same whether the boiling was in covered or uncovered utensils. In the several tests, from 12 to 15 percent of the ascorbic acid was leached from brussels sprouts, from 23 to 29 percent from cauliflower, from 20 to 28 percent from peas, from 24 to 28 percent from spinach, and from 31 to 36 percent from lima beans.

The ascorbic acid content of dried vegetables, V. A. BECKLEY and V. E. NOTLEY (*Biochem. Jour.*, 35 (1941), No. 12, pp. 1396-1403).—This work was carried out in Kenya, Africa, with vegetables grown in the highlands. Immediate drying following harvest, the use of sharp knives of stainless steel, and the maintenance of drying loads sufficiently light to prevent a drop in the temperature (55°-70° C.) of the tunnel drier were found to be essential. Ascorbic acid analyses of the raw material were used as a guide in selecting the most desirable maturity or the most suitable portions of the vegetable for drying.

Cabbage, including the outer green leaves if sufficiently tender, was cut in shreds from $\frac{1}{4}$ to $\frac{1}{2}$ in. wide. Blanching preliminary to drying was not recommended, since it resulted in a product which, although richer in vitamin C than the unblanched, dried product, was unpalatable and unattractive after soaking and cooking (30 min. at an altitude of 5,800 ft.). Cooking losses were kept at a minimum by dropping the dried shreds directly into boiling water. Cauliflower, including a fair proportion of the outer leaves, was sliced and blanched preliminary to drying. Without blanching to soften the tissues, drying was too prolonged and bacterial spoilage developed. Carrots were sliced and dried without blanching, since blanching was found to give low yields and a cooked product very flat as to flavor. String beans, not too mature, were cut into strips and dried without blanching, and the dried product was cooked without pre-soaking by dropping directly into boiling water; blanching was found to reduce the yield and ascorbic acid content and to give a dried product of unsatisfactory color and a cooked product unsatisfactory as to color, tenderness, and flavor.

Potatoes cut into thick chips and blanched for 3 min. in live steam gave a very satisfactory dried as well as cooked product. The dried material held in an open bag for 7 mo., part of which time it was very wet, remained hard and cooked up perfectly.

Effect of blanching on the dehydration rates of vegetables, J. SUGIHARA and W. V. CRUESS. [Univ. Calif.]. (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 21 (1942), No. 5, pp. 139-140, figs. 2).—A number of vegetables were dried, both with and without blanching, in a small air-blast tunnel dehydrator, with air velocity of about 500 linear ft. per minute and low relative humidity, at temperatures varying for the several products from 140° to 160° F. The yield of dried product obtained from the blanched vegetable was higher than from the unblanched in the case of spinach, peas, onions, and corn; the reverse was true for cabbage, string beans, sauerkraut, carrots, potatoes, squash (summer and Zucchini), cauliflower, and beets. In all cases the blanched vegetable dried more quickly than the unblanched, the saving in time being appreciable with cauliflower, peas, and string beans. The sauerkraut, after drying, was gray in color, but on refreshing and cooking returned to the normal color and appearance of sauerkraut. Drying made it milder than regular cooked sauerkraut in flavor and odor.

TEXTILES AND CLOTHING

Textile fabrics and their selection, I. B. WINGATE (*New York: Prentice-Hall, 1942, rev. ed., pp. XV+624, figs. [78]*).—This book, one in a series consisting of several independent studies of the various phases of retailing, treats comprehensively of the question of textiles from the consumer point of view, with the purpose of presenting the facts about textiles that make for satisfaction in use. "It outlines pertinent facts that will guide the customer in making the best selection for his or her needs; it interprets, for the consumer-buyer, the terms found on tags and labels affixed to textile fabrics sold in stores, as well as the terms found in factual advertisements; and, finally, it emphasizes the selling points of textile fabrics that will make a retail salesman more intelligent." The first part, dealing with consumer demand and fabric construction, considers the consumer movement and what the consumer wants to know about textiles; the classification and recognition of textile fabrics; the importance to the consumer of cotton, linen, rayon and nylon, silk, and wool; plain and fancy weaves; knitted cloth; and the finishing, dyeing, and printing of cloth. The second part, dealing with the selection of appropriate fabrics, considers the points involved in the selection for women's, girls', and infants' wear; men's and boys' wear; domestics; period styles in home furnishings and rugs, and for draperies, curtains, and upholstery. In the appendix are given the Federal Trade Commission Trade Practice Rules for the rayon industry, shrinkage of woven cotton yarn goods, the silk industry, the linen industry, the hosiery industry, and rules and regulations under the Wool Products Labeling Act of 1939. An extensive bibliography refers to general and specialized works on textiles, to periodicals, and to general sources of information for consumers and salespeople.

Textile photomicrographs made at low power by fluorescent light, H. H. BROADFOOT and E. R. SCHWARZ (*Textile Res.*, 12 (1942), No. 6, pp. 2-6, figs. 4).—It is pointed out that fluorescent lighting possesses the advantages of even illumination, prevention of heating of the sample, control of surface lighting in the matter of shade and shadow, short time of exposure, and considerable reduction in cost of equipment. It is recommended in textile photography where high magnification is not required, such as in showing details of construction,

defects in manufacture; and results of service or of tear, bursting, impact, or tensile strength tests.

Research aids: Air permeability instrument (*Textile Res.*, 12 (1942), No. 7, pp. 20-22, figs. 2).—The improved instrument, described and illustrated, was developed at the National Bureau of Standards by H. F. Schiefer and P. M. Boyland. It permits a determination to be made on any part of a piece of cloth without cutting. Having been found entirely satisfactory in routine use, it is recommended for testing parachute cloth, fabrics for wind-resistant clothing, blankets, etc. In the test the fabric is held firmly over a very small opening mounted in a table top. Air is drawn, at a rate which may be adjusted, through the fabric into a chamber connected with a horizontal manometer for measuring the pressure drop across the fabric and through an orifice for measuring air flow into a chamber connected with a vertical manometer. The amount of air flowing through a fabric under test is determined from the pressure drop indicated by the vertical manometer and the calibration of the orifice which is used. A set of nine orifices covers the range of air permeability from 1 to 700 cu. ft. per minute per square foot of fabric. The air permeability is usually measured for a pressure drop across the fabric of 0.5 in. of water. The appropriate size of the orifice to use for a fabric, the approximate permeability of which is not known, is determined by a trial run. The pressure drop indicated by the vertical manometer should be more than 3 in. If it is less, a smaller orifice should be used to obtain precision in the instrument.

Sequoia bark fibers (*Textile Res.*, 12 (1942), No. 4, pp. 26-27, fig. 1).—This brief report concerning a product developed through research indicates that the short sequoia bark fibers that collect separately from the long ones used in making an insulating material can be blended with wool, and that the resulting blend can be carded, combed, and spun into yarns suitable for the manufacture of woven or knitted fabrics resembling all-wool materials in appearance and handle. The blended fibers can also be made into felts.

Synthetic-rubber thread (*Textile Res.*, 12 (1942), No. 7, pp. 18-19, fig. 1).—The development by a commercial rubber firm of a synthetic rubber thread is announced. At present the entire supply is restricted to military uses. In rigorous tests the synthetic rubber thread showed 700 percent elongation, comparable to the rubber thread previously made from natural rubber compounds; the recovery from stretch was about the same; and the stability under accelerated aging tests was somewhat better than that shown by thread from natural rubber. Synthetic thread resisted the effects of dyeing or bleaching and the action of perspiration much more than did the natural rubber products and had a much greater resistance to cutting by the needles of the knitting machines.

Two-way stretch (*Textile Res.*, 12 (1942), No. 6, pp. 18-21, figs. 2).—A brief outline is given of the research leading to the development of elastic yarns or threads of such fineness that they could be knit on fine-gage machines or woven into sheer fabrics. Processes involved in the manufacture of the several types of elastic yarns are noted briefly, and applications in the textile industry are cited.

Determination of Aralac (*Textile Res.*, 12 (1942), No. 6, pp. 24-25, fig. 1).—The tentative method proposed for the determination of Aralac (casein fiber) in admixture with wool, viscose rayon, acetate rayon, or cotton is based upon the determination of phosphorus in an acid digest of the fabric sample. Of these fibers Aralac alone contains phosphorus. The percentage of this element as determined is calculated directly to percentage of Aralac on the basis of a phosphorus content of the fiber of 0.82 percent. The method is not suitable for a determination of Aralac in admixture with rabbit fur.

HOME MANAGEMENT AND EQUIPMENT

Food habits of consumer groups in small towns of Alabama that affect farmers' markets, J. H. BLACKSTONE and B. T. INMAN (*Alabama Sta. Bul.* 252 (1942), pp. [1]+68, figs. 7).—This survey of the amount of food consumed, produced, and purchased by representative groups of people in three small Alabama cities—Hartselle, Notasulga, and Andalusia—was undertaken in the interest of helping local farmers adjust their production of food, as a possible cash crop, to the local market demand in effective price and quality competition with distant producers. The survey, considered in some detail, showed that the respective yearly per capita consumption was for the three towns 1,460, 1,447, and 1,281 lb.; 74, 60, and 85 percent of the food was purchased, most of the rest being produced at home; the food purchases in Andalusia varied with the income of the consumer groups from a yearly per capita of 700 lb. in the lowest income group to 1,500 lb. in the highest; more than four-fifths of the purchased vegetables and all of those home-produced were in the fresh form; of fruits and nuts, which tended to be luxury foods, about 85 percent were purchased, and about half of the kinds were unadapted to production in the State; per capita consumption of livestock products and fish was greater than for any other group of foods; and miscellaneous products, notably flour, were largely bought from distant sources. The findings of this survey considered in relation to the local farm production situation suggested that farmers might profit by planning to produce, with the least interference to major cash crops, those crops and livestock products most in demand by consumers; by adapting packaging, grading, and pricing to local demands; by adjusting production and storage schedules to have a large amount of produce for sale when the local supply is low, but to maintain market contacts and customers throughout the year; by dealing frankly and considerately with the stores; and by establishing additional market facilities such as roadside stands and curb markets.

[Equipment studies by the Indiana Station] (*Indiana Sta. Rpt.* 1941, pp. 76–77, fig. 1).—This progress report (E. S. R., 80, p. 142) summarizes an extension of studies by G. M. Redfield and R. L. Witz of equipment and methods for freezing and storing farm produce, and by Redfield and O. D. Milligan of small electric mixers and beaters for household use.

Family finance in wartime: Home economists' responsibilities, J. V. COLES. [Univ. Calif.]. (*Jour. Home Econ.*, 34 (1942), No. 3, pp. 149–154).—This paper summarizes briefly the financial situation of the family as affected by the present changes in income, increase in prices, decrease in goods available, demands for wartime savings and taxes, and preparation for postwar finances; and discusses ways of meeting this situation through adjusting consumption spending wisely, controlling finances carefully, and buying efficiently and with regard to protecting consumer interests. Some specific suggestions are made to home economists for ways of meeting the responsibilities imposed by this situation.

Physical properties of certain all-silk and all-rayon dress fabrics, E. E. STOUT and H. FLETCHER. (Kans. Expts. Sta.). (*Jour. Home Econ.*, 34 (1942), No. 4, pp. 245–251).—This study, presented in some detail as to materials, methods, and results, is summarized as follows:

"Pure-dye silks are not invariably superior to the rayons, as many persons believe. The weave has something to do with how much punishment a fabric can take. Among the satin crepes tested in this study silk forged ahead in average breaking strength. But among the flat crepes, acetate rayon was in the lead; and among the taffetas, viscose rayon. Dry cleaning neither weakened the fabrics nor caused excessive shrinkage."

MISCELLANEOUS

Report on the agricultural experiment stations, 1941, J. T. JARDINE, H. L. KNIGHT, ET AL. (U. S. Dept. Agr., Off. Expt. Stas., Rpt. Agr. Expt. Stas., 1941, pp. 128).—This report is discussed editorially on page 613.

High lights in agricultural research in Idaho: Forty-ninth Annual Report [of Idaho Station] for the year ending December 31, 1941, C. W. HUNGERFORD ET AL. (Idaho Sta. Bul. 244 (1942), pp. 64, fig. 1).^{*}

Research solves farm problems: Fifty-fourth Annual Reports of [Indiana Station], 1941, H. J. REED, W. V. LAMBERT, ET AL. (Indiana Sta. Rpt. 1941, pp. [2]+114, figs. 11).^{*}

Fifty-fourth Annual Report of the [Michigan Station], 1941, V. R. GARDNER (Michigan Sta. Rpt. 1941, pp. 103-118).—This consists mainly of lists of publications and projects.

Report of the Puerto Rico Experiment Station, 1940, [A. LEE] (Puerto Rico Sta. Rpt. 1940, pp. II+103, pl. 1, figs. 38).^{*}

The San Jóaquin Experimental Range, C. B. HUTCHISON and E. I. KOTOK (California Sta. Bul. 663 (1942), pp. 145, pls. 2, figs. 19).—Following an introduction and a description of the experimental area, the latter by M. W. Talbot, J. W. Nelson, and R. E. Storie, six papers are presented as noted elsewhere in this issue.

Notes on conservation in the Americas, H. J. COOLIDGE, JR. (Chron. Bot., 7 (1942), No. 4, pp. 155-163, fig. 1).—This article, on the conservation of natural resources, includes plants and animals, the physical aspects, and the population with its general distribution and its probable distribution and land uses in the years to come. With the exception of Mexico, it excludes North America from consideration.

Resefia agrícola del Ecuador [Conspectus of the agriculture of Ecuador], E. MOLESTINA O (Chron. Bot., 7 (1942), No. 4, pp. 167-169).

Catalogo de publicaciones periodicas científicas y técnicas [Catalog of scientific and technical periodical publications] (Buenos Aires: Soc. Oient. Argentina, 1942, pp. XX+342).—This is a union list of the periodicals received in the libraries of 64 Argentine institutions.

^{*}The experimental work reported is for the most part referred to elsewhere in this issue.

NOTES

Colorado Station.—A portable dehydrator is being built for experiments with fruits and vegetables. The cost is about \$100, and it is believed to be practicable for family use.

Iowa Station.—A 480-acre farm near Crystal Lake in Hancock County has been purchased for experiments on peat land. The work is expected to deal largely with vegetable crops.

Indiana Station.—Efforts are being made to increase the menthol content of domestic peppermint oil, mainly produced in Indiana and Michigan. In the past menthol recovery has not been attempted in this country, and about 500,000 lb. have been imported annually from Japan.

Experiment Station Seed Shipments to Russia.—According to an announcement by Russian War Relief, Incorporated, a shipment by airplane of new varieties of disease-resistant seeds contributed by experiment stations in this country and Canada has been received in Moscow by the Lenin All-Union Academy of Agricultural Sciences. The shipment includes the more familiar grain and vegetables of Russia—wheat, oats, barley, tomatoes, carrots, beets, cucumbers, cabbage, and corn—and a few vegetables hitherto little cultivated there—spinach, collards, celery, peas, squash, and eggplant. The stations accredited with the various seeds are as follows: California, Connecticut [New Haven], Indiana, Kansas, Massachusetts, Michigan, Minnesota, New Jersey, [New York] Cornell, Ohio, Tennessee, Virginia Truck, Washington, Wisconsin, and Saskatchewan.

Agricultural Engineering Research in Great Britain.—An Agricultural Machinery Development Board set up early in 1942 has established a National Institute of Agricultural Engineering at Askham Bryan, near York. The nucleus of the institute is the Institute of Research in Agricultural Engineering, transferred from Oxford by the university and with its director, S. J. Wright, continuing in charge. Temporary housing in the new location will be provided in buildings belonging to the Yorkshire Council for Agricultural Education, but eventually it is intended to build permanently on a nearby site. The main functions of the new institute will be to act as a general clearing house for information about agricultural machinery and its use, to carry out tests or demonstrations of new or improved implements, and to undertake experimental and demonstration work on the better utilization of existing equipment.

New Journals.—*Agenda*, a quarterly journal of reconstruction, has been begun by the London School of Economics and Political Science at Southfield House, Hill Top Road, Oxford. The initial number included an article by the late Sir Daniel Hall entitled *Reconstruction and Agriculture* (pp. 12–25) and one by Dr. L. Dudley Stamp on *Principles of Land Utilization* (pp. 25–37).

Bibliography of Agriculture is being issued monthly, by the U. S. D. A. Library, in four sections. Section A, *Agricultural Economics and Rural Sociology*, supersedes *Agricultural Economics Literature*; Section B, *Agricultural Engineering*, supersedes *Current Literature in Agricultural Engineering*; Section C, *Entomology*, supersedes *Entomology Current Literature*; and Section D, *Plant Science*, supersedes *Plant Science Literature*.

EXPERIMENT STATION RECORD

VOL. 87

DECEMBER 1942

No. 6

RESEARCH AT THE SECOND INTER-AMERICAN CONFERENCE OF AGRICULTURE

The 12 years which have elapsed since the holding of the First Inter-American Conference on Agriculture, Forestry, and Animal Industry in Washington, D. C. (E. S. R., 63, p. 603) have seen notable progress in the mobilization of agriculture in the Americas. This advance was well brought out in the proceedings of the second conference, held in Mexico City from July 10 to 16, 1942. This conference gave many evidences of an ever-widening appreciation of the value of joint effort and close cooperation.

In spite of transportation difficulties and an advancement of the date by several months to spur concerted action, all of the 21 Republics were represented at the sessions. Among the 170 delegates in attendance were five ministers or secretaries of agriculture and an equal number of national directors of agriculture. The delegation from the United States was headed by Secretary Claude R. Wickard, who served as a vice chairman, and included a considerable number of specialists from the Department and the land-grant institutions.

An address by Secretary Wickard at the opening plenary session took the form in large part of a report to the hemisphere on the war effort of the United States as regards agriculture. He advocated as measures worthy of consideration by the conference the establishment of cooperative agricultural experiment stations, agreements or contracts to increase production of strategic commodities, improvement and integration of communications, plans for farm and industrial labor, common management of surpluses, provision for relief after the war, finding ways of distributing maximum production to the people, raising more crops for home consumption, and the strengthening of our competitive positions as a hemisphere by better production methods, higher yields, mechanization, improved transportation, and new processing technics. In conclusion he offered "both for the present and the future" the services of the Department to other nations and especially those of the Western Hemisphere through "its scientists,

economists, engineers, and technicians, and the facilities of its laboratories and experiment stations."

The work of the conference was carried on in 12 subject-matter sections, before which about 70 papers were presented. Of these sections, that on education and research centered around topics of direct interest to readers of the *Record*, but there was also much of significance in other sections. Thus the section on products of present-day importance recommended the establishment of cacao institutions in Ecuador and other countries. That on rural organization advocated an integrated system of rural education and the inclusion of home economics instruction and research in colleges of agriculture. The section of soils and agronomy discussed the organization of a hemisphere soil society, standardization of terminology, and the making of a hemisphere soil map. A resolution of the entomology and plant pathology section recommended parallel and coordinated investigations of insects, and the section of climatology suggested close cooperation between phytophysiolologists, phytopathologists, and agrologists on the one hand and meteorologists and climatologists on the other. The forestry section advocated the strengthening of forestry education and research. The program of the section on chemistry and technology, dealing with the need both for adapting agricultural products for new uses in the war effort and for utilizing normal surpluses, centered around research in these lines and led to a resolution urging its continuance and upbuilding.

The section on education and research gave much attention to problems of tropical America and inter-American collaboration in agricultural research and extension. Resolutions were adopted recommending the exchange of information concerning scholarships available in the respective countries, the publication of an inter-American agricultural magazine, and the establishment of cooperative agricultural experiment stations, and endorsing the Inter-American Institute of Agricultural Sciences. The program of this proposed institute was explained by Dr. E. N. Bressman, who since the conference has been named as its first director. Costa Rica has been selected as the site of the institute, and its object has been announced as "the advancement of agriculture in the American Republics through teaching, research, experimentation, extension activities, general education, and training in agriculture and related arts and sciences."

For obvious reasons many of the papers at the conference dealt with specific crops and situations, but that entitled Agricultural Science and the People's Welfare, by Dr. E. C. Auchter, head of the Agricultural Research Administration, was conspicuous for its discussion along general lines of research ideas and ideals. Our duty as agricultural scientists, he declared, is threefold: "First, to keep on

everlastingly seeking for more of the truth, each of us in that field in which our particular work lies; second, to see to it that whatever truths we discover become as widely known as possible; and third, to advance the use of these truths for human well-being." Pointing out the huge task now faced by agricultural science and the need for maximum efficiency, he pleaded first of all for a critical study of our research procedure to see where we can "cut corners wherever possible, eliminate slow and cumbersome procedures that have grown up as agricultural science became divided into more and more special compartments, and bring people together for quick, common action. . . . We cannot afford to be slow in meeting the problems of human welfare that face us all with increasing urgency."

At the same time he maintained that in connection with war work, "the research worker must do more than follow the trends of current events; he also has a responsibility as a leader who looks ahead. Where scientific work is closely and directly tied up with the public welfare, as ours is, this responsibility is especially great. If we exercise it wisely, we can be sure of public approval in the long run."

Closely related to the "need to carry along certain projects whether or not they seem to have immediate value," is, according to his view, the question of "basic research." Citing several instances in which it was found that "either basic research precedes the practical applications of science or a certain amount of this kind of research is found to be necessary somewhere along the line to clear up obscurities that block further progress," he made the point that "in research there is no single road to practical results. If we keep our eyes constantly and exclusively on what seem to be immediate needs, we miss some of the richest fruits of scientific work—the fruits that grow from the discovery of important fundamental facts." For these reasons, freedom of inquiry "to explore all kinds of facts wherever they may lead is absolutely necessary if science is to advance human welfare."

The larger aspects of the conference as a whole were well summarized at its close in a statement by Secretary Wickard in which he said in part, "the Second Inter-American Conference of Agriculture impressed me as a demonstration of the will of the people of the Americas to live and work together. Of greatest immediate importance, naturally, are the steps that were taken to make available agricultural products essential in carrying on the war. In addition, the conference lost no opportunity to encourage projects that will have a long-time effect." Undoubtedly the conference measurably advanced both types of programs. Especially noteworthy and encouraging was its recognition of research as an indispensable aid.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Arizona Station] (*Arizona Sta. Rpt. 1941*, pp. 6-7, 40-42).—Fluorine investigations included work on the bone filter, removal of stain from mottled teeth with hydrogen peroxide, and relation of well depth to the fluorine content of the water. Work on the chemical composition and carotene content of Arizona forage plants and on blood analysis of cattle is also briefly discussed.

[Chemical investigations by the New Haven Station] (*Connecticut [New Haven] Sta. Bul. 452 (1942)*, pp. 7-9).—H. B. Vickery et al. report upon studies of plant organic acids; proteins and amino acids, noting a reinvestigation of the crystalline proteins of some of the cucurbits, a new method for the preparation of histidine, and the commercial application of a method for preparing the amino acid amide glutamine; and protein nutritional investigations with the globulin of watermelon seed.

[Chemical investigations by the Florida Station] (*Florida Sta. Rpt. 1941*, pp. 84-86, 122-126, 128-130, 153-156).—Brief reports by A. L. Stahl, J. C. Cain, J. R. Henderson, G. M. Volk, L. H. Rogers, R. A. Carrigan, C. E. Bell, H. W. Winsor, R. C. Hughes, C. K. Clark, F. F. Cowart, and C. R. Stearns, Jr., include a study on the preservation of citrus juices and pulps; storage and preservation of miscellaneous fruits and vegetables with phtofilm, ultraviolet light, and brine; citrus maturity studies; soil and plant relationships; physical and chemical methods of complete and partial analysis for soils and related materials; a study of the so-called "quick methods" for determining soil fertility; composition of Florida soils; effects of certain mineral elements on plant growth, reproduction, and composition—chemical phase; packing house research; effect of washing on shrinkage and stem-end control in oranges; studies on maturity and quality standards of oranges; and added color research.

[Chemical and bacteriological investigations by the Massachusetts Station] (*Massachusetts Sta. Bul. 388 (1942)*, pp. 19-20, 29-31, 71-74).—These included a comparative study of certain media employed for fecal-flora studies, by J. E. Fuller and I. Fried; the bacteriology of chocolate sirups, cocoa powders, and chocolate milk, by Fuller, R. W. Swanson, and W. S. Mueller; studies of methods for determining the sanitary quality of drinking utensils, by R. L. France, W. E. Cassidy, and Fuller; the effectiveness of certain detergents and procedures employed for the cleansing of eating and drinking utensils, by France; lignin and its relation to the absorption of minerals by plants and chemical investigation of the onion, both by E. Bennett; chemical changes in the cooking quality of vegetables and investigations on the nutritive value of fishery products as human and animal food, both by M. E. Freeman and W. S. Ritchie; physicochemical properties of starches, by Freeman; cranberry products research, by C. R. Fellers and A. S. Levine; apple products, including apple juice, by W. B. Esselen, Jr., Levine, Fellers, and C. C. Strachan; fruit jellies and jams, by Levine, S. G. Davis, and Fellers; vitamin C content of catsup, by Esselen and H. Fran; change in oxida-

tion-reduction potential in packaged fruit juice, by Esselen; glass container research, by Fellers, Esselen, W. H. Fitzpatrick, E. L. Moore, and J. J. Powers; crab meal research, by Fellers and J. Lubitz; dextrose investigations, by Fellers, Levine, and L. Tarkow; and preservative values of organic acids, by Levine, R. E. Morse, and M. G. O'Connor.

Insistimos en el problema de las grasas [The urgency of the fat problem], J. H. RAMÍREZ (*Agr. Expt. [Puerto Rico Univ. Sta.]*, 2 (1942), No. 3, p. 3).—A plea for additional research on fats and oils.

A support for reflux condensers, E. J. BENNE. (*Mich. Expt. Sta.*). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 3, p. 264, figs. 4).—The author describes and illustrates a device providing sufficient elasticity in the mounting to permit vigorous rotation of the attached flasks without need to loosen clamps. A support for six reflux condensers was constructed from common materials at slight cost and proved to be convenient and effective in use with either a water bath or electric hot plate.

Spectrophotometric determination of iron.—I, Use of mercaptoacetic acid; II, Use of 2,2'-bipyridine, R. A. KOENIG and C. R. JOHNSON (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 233-238; 143 (1942), No. 1, pp. 159-163).—The present studies were "designed to adapt for spectrophotometric use a number of the best colorimetric methods for iron, to obtain accurate calibration data over a wide range of iron concentrations, and to establish the validity of these data for determining iron in solutions containing common acids in concentrations that occur in analytical solutions prepared by various wet and dry methods of ashing." Details are given as to apparatus and reagents, the calibration experiments are summarized, and the procedures are given in detail for accurate spectrophotometric methods for determining iron with mercaptoacetic acid and with 2,2'-bipyridine.

Determination of iron in three diets, R. A. KOENIG and C. R. JOHNSON (*Food Res.*, 7 (1942), No. 2, pp. 130-134).—Three different diets were carefully analyzed for iron content by seven different methods of procedure, involving determinations by the ferron, mercaptoacetic acid, and α,α' -dipyridyl methods and dry and wet ashing procedures. Further variations were introduced in the case of the wet ash method by utilization of the acid digest (1) directly, after some concentration; (2) after evaporation to dryness and subsequent bleaching treatment; or (3) after evaporation and subsequent electrical ignition. The procedure applied in the two latter cases was conducted with or without hydrolysis to convert pyrophosphate to orthophosphate.

The results indicated that essentially correct values for total iron were obtained by both the ferron and mercaptoacetic acid methods when the sample was digested by the wet ashing procedure, provided, in the ferron method, care was taken to hydrolyze pyrophosphate. In the mercaptoacetic acid method, the presence of the ortho- and pyrophosphate could, in most cases, be disregarded. Slightly low values were obtained by procedures involving ignition due probably to volatilization of iron. While wet ashing was preferable, organic matter resisting attack by the acid mixture had to be destroyed eventually for determination of total iron. Results obtained by direct utilization of the acid digest ((1) above) showed that even after perchloric acid ashing a considerable part of the iron did not react when the usual colorimetric methods were applied; this and the nature of the residue obtained upon evaporation to dryness suggested that a portion of the iron was held in firm organic combination. It was concluded tentatively that direct determinations on the acid digest may give a measure of available iron. Analyses by the dipyridyl method supported this conclusion.

Distribution of salt in butter: A volumetric micromethod, C. L. OGG, I. B. JOHNS, W. H. HOECKER, and B. W. HAMMER. (Iowa Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 3, pp. 285-286, fig. 1).—The microprocedure consists in weighing in a microspoon a sample of butter of approximately 0.2 mg. picked with a dissecting needle under the microscope, ashing the weighed sample, and titrating with standardized silver nitrate solution. All the necessary apparatus is described in detail. It is stated that "the value of the method lies in the study of the salt distribution in butter, and it is particularly useful in the study of the effect of salt distribution on bacterial action."

A practical moisture test for American Cheddar cheese, I. A. GOULD (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 318-321).—This is a description of the oil-salt method previously reported (E. S. R., 80, p. 152). Seventeen samples of American Cheddar cheese when analyzed for moisture content by this method and the 100° C. oven method were found to contain an average of 34.76 and 34.86 percent moisture, respectively.

Adaptation of the Scudi colorimetric method for pyridoxine, O. D. BIRD, J. M. VANDENBELT, and A. D. EMMETT (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 317-322).—The Scudi method (E. S. R., 87, p. 11) for determining pyridoxin was modified to admit of routine determinations on pharmaceuticals and biological materials. Graded amounts of the unknown, estimated to contain from 5 γ to 100 γ of pyridoxin, were weighed out into calibrated test tubes, treated with 2 cc. of citrate-phosphate buffer (pH 3.0), diluted to 5 cc., and freed of interfering substances by adsorption of the pyridoxin on superfiltrol. Adsorption was most complete at pH 3.0, and 1 mg. of adsorbent to each microgram of estimated pyridoxin permitted complete adsorption and likewise complete elution. The tubes, with added adsorbent, were allowed to stand 30 min., with frequent shaking. After centrifuging the liquid was decanted, and the adsorbate, washed with the buffer solution, was treated with 10 cc. of a butanol solution containing 62.5 γ of 2,6-dichloroquinonechloroimide per cubic centimeter. Following this, veronal buffer was added which brought the pH to 7.8-8.0 and allowed the characteristic blue color to develop. Thus, elution and color development occurred simultaneously. The resulting butanol-water emulsion was separated by centrifuging, the butanol layer was decanted into the colorimeter tube, and the amount of color was determined in an electric photometer with a filter transmitting at approximately 650 m μ . The color in all the tubes of the unknown and of the standard was allowed to develop for the same length of time before making the color readings. The pyridoxin content of each unknown tube was determined in terms of the standard by reference to the curve drawn from photometer readings obtained for tubes containing known amounts of pyridoxin. The presence of 50 γ or 500 γ of thiamin, riboflavin, nicotine acid, sodium pantothenate, or 10 times these amounts of ascorbic acid did not influence the accuracy of the assay. Ascorbic acid, however, had to be first eliminated by the adsorption and elution technic, since it destroyed the blue color produced in the test. In practice the method proved to be rapid and simple.

Vitamin methods.—I, An improved procedure for estimating vitamin B₁ in foodstuffs and biological materials by the thiochrome test, including comparisons with biological assays, L. J. HARRIS and Y. L. WANG (*Biochem. Jour.*, 35 (1941), No. 8-9, p. 1050-1067, figs. 2).—The procedure, presented in detail, was based upon the method described for urine by Wang and Harris (E. S. R., 83, p. 851). For application to foodstuffs, two additional steps were required, the one being a preliminary extraction with acidified water (the procedure varying somewhat according to the nature of the product) and the other, digestion with papain and takadiastase to convert cocarboxylase into thiamin, to break down proteins, polysaccharides, etc., and to remove inhibitors. Other features

included washing of the digest with isobutanol to remove interfering substances; omission of adsorption because of variable losses; conversion into thiochrome in the presence of methanol, and with the addition of the $K_4Fe(CN)_6$ before the NaOH in order to protect against loss by oxidation; washing of the thiochrome layer with water to permit accurate differentiation between cocarboxylase and free thiamin, and to eliminate nonspecific fluorescent substances and pigments; and visual comparison of fluorescence with the aid of light filters and blank controls.

Results obtained by the method were in good agreement with those obtained by biological assay, chiefly by the bradycardia method, in tests with over 50 foodstuffs varying in thiamin content from 0.03 to 200 International Units per gram and including wheat meals and flours, other cereals, breads and biscuits, yeast preparations, meat and animal tissues, dairy products, and a few vegetables, fruits, and fish. In 75 percent of the cases the biological and chemical values differed by less than 15 percent and in 87 percent of the cases by less than 30 percent; the larger percentage errors were found only with the foods poor in thiamin or in dried products difficult to extract. Results could be duplicated with an error of about ± 5 percent when the method was applied to solutions containing 0.1 $\mu g.$ of thiamin per cubic centimeter and with an error of ± 10 percent with 0.03 $\mu g.$ per cubic centimeter. The method was found to be rapid and easy to apply.

Vitamin methods.—II, A note on vitamin B₁ in urine as determined chemically and biologically, L. J. HARRIS and Y. L. WANG (*Biochem. Jour.*, 35 (1941), No. 8-9, pp. 1068-1070, fig. 1).—Further tests with the improved thiochrome method of Wang and Harris (*E. S. R.*, 83, p. 851) applied to two urines, one high and one low in thiamin, showed that the results obtained agreed well with those obtained by biological tests (bradycardia method); for one urine the biological value was 110 percent of the chemical and for the other 101 percent. Recovery tests confirmed the reliability of the method.

Potentiometric determination of vitamin C, J. B. RAMSEY and E. L. COLLOCHMAN. (Univ. Calif.). (*Indus. and Engin. Chem., Analyt. Ed.*, 14 (1942), No. 4, pp. 319-321).—The potentiometric method described for the determination of ascorbic acid in pure solution or in citrus juices is carried out in an inert atmosphere (N_2). It depends upon a stable potassium iodate solution as the only standard oxidant, and at the same time makes use of the specific oxidation of ascorbic acid by 2,6-dichlorophenolindophenol. Standardization of the unstable dye solution is thereby eliminated.

Extraction of carotene from plant material: A rapid quantitative method, L. A. MOORE and R. ELY. (Mich. Expt. Sta.). (*Indus. and Engin. Chem., Analyt. Ed.*, 13 (1941), No. 9, pp. 600-601, fig. 1).—A rapid quantitative method for the extraction of carotene from such plant materials as fresh green grasses and legumes, hays variously cured, and silages, involving the use of a commercial mechanical mixer in conjunction with a foaming solvent, was developed. A suitable mixture of 95 percent ethyl alcohol and petroleum ether produced a foam which prevented the splashing and jumping of the solvent. This method reduced the time required to extract carotene from plant material. The carotene values obtained agreed closely with those obtained from the usual alcohol extraction method.

Preserving and germicidal action of various sugars and organic acids on yeasts and bacteria, F. J. ERICKSON and F. W. FABIAN. (Mich. Expt. Sta.). (*Food Res.*, 7 (1942), No. 1, pp. 68-79).—The order of preserving and germicidal action of the sugars toward the bacteria studied was fructose > dextrose > sucrose > lactose. The thermophiles were more susceptible to sugar than were *Streptococcus lactis* and *S. liquefaciens*. The yeasts were more resistant than

bacteria to all the sugars studied. The preserving concentrations of fructose and dextrose were the same for yeasts, while for sucrose a 5-15 percent greater concentration was required. Lactose had no preserving action as against the yeasts. Fructose and dextrose were the only sugars having a germicidal action on all the yeasts. Sucrose killed only one yeast, *Saccharomyces cerevisiae*.

In terms of the number of grams of each acid in 10 cc. of broth, the preserving value of the acids for the bacteria was lactic > acetic > citric. Based on pH, the order was acetic > citric > lactic. The streptococci were considerably more resistant to acids than were the thermophiles. The yeasts were more tolerant to the acids than the bacteria. An acid strength of from 0.5 to 5 N was required to bring about a preserving and germicidal action against the yeasts, while the bacteria required a normality of from 0.1 to 0.3. The order of effectiveness of the acids in the preserving and germicidal range was acetic > lactic > citric for the yeasts, irrespective of whether it was based on pH or the percent of acid added.

For bacteria the order of effectiveness of the acids in combination with sugars was lactic > acetic > citric. Fructose and dextrose were more effective than either sucrose or lactose in combination with the acids. The thermophiles were not able to withstand a combination of fructose or dextrose with any of the acids, less than 2.5 percent of the sugars exerting a germicidal action. *Streptococcus lactis* and *S. liquefaciens* still retained their greater resistance. As against the yeasts, dextrose and fructose in combination with the preserving quantity of the respective acids were germicidal at a lower percentage than either sucrose or lactose in combination with the same amount of acid. In general, it took less dextrose and fructose to bring about a germicidal action with acetic than with lactic and less with lactic than with citric acid. Sucrose in combination with the preserving quantity of citric acid exerted a germicidal action on only two of the yeasts—*Saccharomyces cerevisiae* and *S. ellipsoideus*. No germicidal action was exerted by lactose in combination with any of the preserving quantities of the acids. In an acid and sugar combination the acid is the more important factor of the two in producing a germicidal effect on micro-organisms.

Freezer burning prevented by water, E. W. HENDERSON (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 304-307).—To compare losses by dehydration, two 100-piece lots of roaster sized chicken were wrapped in 10 packages, each consisting of 10 pieces, with ordinary waxed butcher's paper and string. Both lots were frozen for 48 hr. at -25° F. Both lots were removed for the time required to glaze one lot by immersion in water. Both lots were returned to the original storage for 2.5 mo. At the end of the storage period all pieces in both lots except the giblets appeared fresh, normal, and free from "freezer burn." The glazed lot gained 0.4 percent in weight and the unglazed lot lost approximately 3 percent. The giblets in both lots lost from 10 to 23 percent in weight. Giblets should be either frozen together in a block of ice or placed in the bottom of a waxed paper package and glazed by immersing in water when fresh and freezing at once.

A search for new uses for low-grade tobacco (*Kentucky Sta. Rpt. 1941, pp. 12-13*).—Various constituents were examined to find possible commercial uses.

AGRICULTURAL METEOROLOGY

Climate and accelerated erosion in the arid and semi-arid Southwest with special reference to the Polacca Wash Drainage Basin, Arizona, C. W. THOMTHWAITE, C. F. S. SHAMPE, and E. F. DOSCH (*U. S. Dept. Agr., Tech. Bul.* 1396 (1942), pp. [2]-134, figs. 57).—Accelerated stream trenching or arroyo cut-

ting in the Southwest has been noted for over 50 yr. Ranges once carrying 10,000 head of cattle can now scarcely support one-quarter as many. Valleys converted by the first white settlers into prosperous farms are now deeply cut badlands unsuitable even for grazing. Apropos of this disturbing situation, the monograph here presented considers in detail studies of the climates of the Southwest, erosion in the Polacca Wash, and accelerated erosion in the Southwest.

Because of the more critical meteorological and vegetational balance, climatic variations produce far greater differences in plant growth and erosion in dry than in humid regions, and variations in precipitation and temperature from year to year may result in marked shifts of the climatic pattern. However, examination of evidence in tree rings, lake levels, cutting and filling of valleys, and in the development of pueblo peoples failed to reveal proof of any significant climatic change in the Southwest in the last 2,000 yr. Under natural conditions in the Polacca Wash and in most of the Southwest, the plant cover protected the soil and retarded the flow of water off the lands, but with acceleration of erosion, short discontinuous gullies became more numerous. As this continued, more of the gullies lengthened until they joined other gullies farther along the wash. This gully cutting has been the most obvious and destructive of the erosion forces at work in the Polacca drainage, but sheet erosion and wind erosion are also reducing the value of the lands, though the latter agency may be beneficial locally by helping to check erosion from running water.

There was no evidence of any appreciable uplift or tilting of the land or any change of the base level that might explain the recent acceleration of erosion in the Southwest, but owing to the delicate adjustment of vegetation to climate a succession of even a few dry years may so impoverish the plant cover that rains of even moderate intensity can initiate a period of increased erosion. The margin of safety in semiarid lands is slight and hence the amount of vegetation that can be safely grazed is small. In most of the Southwest the permissible amount has long since been exceeded. The Polacca drainage is now suffering the results of a grazing economy introduced to the Indians about 1540, though the human and animal population was not heavily concentrated until after the Civil War. It appears to have taken 15-20 yr. for the increased grazing to reduce the vegetal cover far enough so that changes in erosion became recognizable to the inhabitants.

If the removal of vegetation can be curbed and revegetation begun, it may still be possible to check the accelerated cutting so that the damage can be stopped. Changes in methods of herding are seriously needed. A shift from the corraling system to one of rotational pasturage in fenced enclosures would aid greatly in reducing the damage from trampling and would make it possible to allow time for the worst ranges to recuperate. Modernized mechanical aids such as diversion dams, distribution ditches, and spreader structures can be used to keep water out of the gullies and spread it over the valley lands. The accelerated erosion that is damaging the lands of the Southwest appears to have been caused by man, and by proper methods man can check it and reclaim the land for his use.

It is further suggested that the detailed study here presented can be of immediate use in at least two ways: (1) With the cutting off of our major sources of rubber, guayule has come to the fore as a possible substitute. It is native to semiarid areas, and the information here given should prove of assistance to those charged with finding the most suitable sites for producing this vital war material. (2) Analysis of the dry climates of the United States may find a more far-reaching value in the insight it gives to comparable climates in Australia and other theaters of the present war. Through a full understanding of the vari-

ability of these climates, troops of the United Nations can be properly equipped and trained to cope with the weather conditions they will encounter. There are 113 references.

The climates of California according to the Köppen classification, J. E. KESSELI. (Univ. Calif.). (*Geog. Rev.*, 32 (1942), No. 3, pp. 476-480, figs. 4).—As a supplement to the map of distribution of climates in North America recently presented by Ackerman (*E. S. R.*, 85, p. 12), the author here presents and discusses several more detailed maps of the temperature and climatic regions of California. There are 13 references.

Hail as a factor in the regional climatology of the United States, H. LEMONS. (Okla. A. and M. Col.). (*Geog. Rev.*, 32 (1942), No. 3, pp. 471-475, figs. 17).—Formidable among the many climatic evils besetting agriculture is the common hailstorm. No part of the United States is secure, but in certain regions, notably the Great Plains and the central lowland, hail is of such frequency and destructiveness as to constitute a major agricultural hazard to be ranked on a par with drought. The time-areal distribution of hail and the factors influencing it are discussed, and the annual, seasonal, and monthly distribution, based on U. S. Weather Bureau data over a 40-yr. period (1899-1938), is shown on maps. The seriousness of the damage in the two areas above noted lies not only in the frequency of hailstorms but in the fact that the chief crop plants are of types particularly susceptible to such injury and that the period of maximum hail often coincides with the main growth periods of these crops. In other parts of the country hailstorms are only a minor risk, but the unpredictableness of their visitations makes them a phenomenon constantly to be feared by growers of such crops as tobacco, cotton, fruit, and vegetables.

The average growing season and departures therefrom in lower Michigan, V. R. GARDNER (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 312-318, figs. 3).—Following brief comments on the criteria usually employed in classifying seasons as early or late, the following are graphically presented and discussed, viz, the mean minimum, mean average, and mean maximum temperatures recorded at East Lansing for 1921-26 and averages for the 50-yr. period 1890-1939; the monthly mean temperatures for the coldest (1907) and the warmest (1921) years for a 50-yr. period and the average mean monthly temperatures for 1890-1939; the average monthly maximum, mean, and minimum temperatures for the 30-yr. period 1910-39; the average monthly mean temperatures at four stations in the State for this 30-yr. period; and the response of vegetation to differences in temperature, including the range in dates of certain phenological "events" that may be used to measure the relative earliness or lateness of a season and comparisons of the dates for certain of these events in southern and northern points in the "fruit belt" of the State.

Methods of computing a regression of yield on weather, E. E. HOUSEMAN (*Iowa Sta. Res. Bul.* 302 (1942), pp. 861-904, figs. 3).—The method developed by R. A. Fisher for examining the influence of rainfall on the yield of wheat at Rothamsted has formed the basis for a number of investigations, which are briefly noted. Application of Fisher's device gives a regression curve which shows the effect on yield of a unit change in a given meteorological element at any time during the growing season. In this paper the interest is mainly in presenting expeditious methods of handling the data, when applying Fisher's method, in a manner which is understandable by those with only a small knowledge of statistics, and also in including enough computational detail in the illustrations so that they can be used as a guide by the computer. The method is illustrated for two cases, viz, for the regression of yield on one weather factor, and for that on two weather factors simultaneously. For illustration, data on the yield

of Hogue Yellow Dent in corn varietal tests at Lincoln, Nebr., together with rainfall records during the period May 1–August 28, 1906–33, were chosen. Details for the method in the two cases above noted are given and discussed. Tables present the precipitation, yield, and statistical data, and two appendixes discuss, respectively, the derivation of the regression function and an alternative method of calculating the distribution coefficients. There are 10 references.

The incidence of drought in Queensland during the 50-year period, 1886–1935, W. R. BALDWIN-WISEMAN (*Jour. Inst. Civil Engin.* [London], No. 6 (1941–42), pp. 225–226).—This is an abridged report of a study from which it is concluded that close systematic analyses of long-term meteorological records along the lines indicated will afford valuable data for investigating water resources and for a drought index of pasture and crop lands in arid or semiarid areas for use in insurance against drought, in acquisition or lease of lands, and in matters relating to relief or to classification, rehabilitation, or abandonment of marginal lands.

Two cold January nights against a background of thirty winters (a report on fruit bud killing), N. L. PARTRIDGE (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 337–342, figs. 4).—Experience has shown that at irregular intervals destructive winter frosts and freezes are to be expected throughout the lower Michigan peninsula, and that they are much more likely to occur in some parts of the State than in others is evident from the records of 30 winters here mapped to show the frequency with which temperatures of -12° F. or lower have occurred. Most of the minimum temperatures observed by the 74 cooperators of the U. S. Weather Bureau in the region for the month were recorded on the nights of January 7–8 and 9–10, 1942. Details of accompanying conditions are given and the effects on fruit trees, with special reference to peach, are described. Such injury as fruit bud killing is said to be most likely to follow influences delaying the maturity of the tree, and such conditions had prevailed the preceding fall. The safest areas for growing peaches in Michigan are mapped.

What has happened to fruit trees since the midwest blizzard of November 1940, T. J. MANEY. (Iowa Expt. Sta.). (*Amer. Pomol. Soc. Proc.*, 57 (1941), pp. 182–189, figs. 2).—This is a summary of the meteorological conditions during this blizzard in Iowa and of the injuries to horticultural plants, including apple and stone fruit trees, small fruits, and tree and other perennial ornamentals. Histological injuries are also discussed and illustrated.

Orchard cold damage resulting from freeze of November 11–15, 1940, T. J. TALBERT. (Univ. Mo.). (*Amer. Pomol. Soc. Proc.*, 57 (1941), pp. 177–182).—This is a summary of the damage to pome and stone fruit trees of Missouri by this severe freeze, and a review of the literature on cold as a factor in killing tree tissues including crotch and crown injury and contributing factors.

Frost injury to apples, J. M. S. PORTER (*Agriculture, Jour. Min. Agr.* [Gt. Brit.], 49 (1942), No. 1, pp. 60–61).—Due to the unusual condition that in the spring of 1941 frosts of varying degrees occurred during the flowering period, it became possible to make a tentative classification of 43 apple varieties into 3 groups according to their susceptibility to frost. It is presented here, with discussion.

Monthly Weather Review, [March–April 1942] (*Mo. Weather Rev.* [U. S.], 70 (1942), Nos. 3, pp. 43–64, pls. 11, figs. 2; 4, pp. 65–92, pls. 10, figs. 15).—In addition to meteorological, climatological, solar radiation, and sunspot data, these numbers contain the following contributions: No. 3, Summary of the Intensity and Spectral Distribution of Solar Radiation at New Orleans 1881–40, Inclusive,

by H. S. Mayerson, J. S. Graham, and H. Laurens (pp. 43-48); and No. 4, The Development and Trajectories of Tornadoes, by J. R. Lloyd (pp. 65-75).

[Meteorological services and observations by the Florida Station] (*Florida Sta. Rpt. 1941*, pp. 135-137, 157-159, 178, 179, fig. 1).—The functions of the Federal-State Horticultural Protection Service are outlined and the forecasting and temperature survey work by the station is discussed, with a tabulation of verifications of 15,106 temperature forecasts during the winter of 1940-41; the meteorological research by the station is summarized; and records are presented of temperatures, precipitation and evaporation, wind velocity, and barometric pressure for the Everglades Substation and of precipitation and temperatures for the North Florida Substation.

Meteorological report for 1940, F. E. HEPNER (*Wyoming Sta. Rpt. 1941*, pp. 43-45).—Following a brief summary statement for this station, tabulations by months are presented for air pressure, temperature, precipitation, and wind.

Hourly precipitation on the Upper Ohio and Susquehanna Drainage Basins, [January-December 1938] (*U. S. Dept. Agr., Soil Conserv. Serv., 1939, SCS-PC-1-5; 1940, SCS-PC-6-7; 1941, SCS-PC-8-12*, [about 500 pp., 500 figs. each]).—The hourly precipitation is indicated on maps of the basin.

SOILS—FERTILIZERS

The relationship of soil science to land-use planning, R. V. ALLISON. (Univ. Fla.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 17-23).—The current status of this relationship within the Soil Science Society, in our agricultural institutions, and on the land itself is discussed.

[Soil investigations by the Arizona Station]. (Partly coop. U. S. D. A.). (*Arizona Sta. Rpt. 1941*, pp. 8-15).—Progress of research is noted on lysimeter experiments with soil-improving rotations which made Mohave, an upland soil, equal in productivity to Gila, a river bottom soil; the establishment of revegetation on overgrazed and badly eroded areas; the influence of organic matter decomposition on the chemical and physical properties of Arizona soils; rate of nitrification of nitrogenous fertilizers in soils from the Salt River Valley; nodulation of soybeans in Arizona soils; soil reaction as related to plant nutrition; Yuma mesa lands; acidulated fertilizers; soil moisture investigations; and determination of available phosphate in alkaline-calcareous soils.

[Soil investigations by the New Haven Station] (*Connecticut [New Haven] Sta. Bul. 452* (1942), pp. 23, 24).—Organic matter and nitrogen maintenance under intensive cropping conditions, the effects on Connecticut soils of cultivation and erosion, and soil maintenance for vegetables are reported upon by M. F. Morgan et al.

[Soil investigations by the Florida Station]. (Partly coop. U. S. D. A.). (*Florida Sta. Rpt. 1941*, pp. 97-100, 122, 126, 127, 130, 131, 133, 134, 142-143, 160-161, 162-165, 188, fig. 1).—The following are noted by J. R. Beckenbach, D. G. A. Kelbert, J. R. Henderson, F. B. Smith, R. E. Blaser, G. M. Volk, C. E. Bell, G. T. Sims, K. P. Bragdon, M. Peech, V. C. Jamison, J. R. Neller, F. S. Andrews, W. T. Forsee, Jr., F. T. Boyd, B. S. Clayton, and J. D. Warner: Studies on rapid soil tests in relation to response of truck crops and fertilizer recommendations; selection of a suitable rapid soil testing method for use in making fertilizer recommendations; secondary element requirements and deficiency symptoms of vegetable crops; comparative efficiency and economy of different nitrogenous fertilizer materials on sandy soils; soil and water conservation; soil and vegetation surveys in relation to pasture development in Florida; the types and distribution of micro-organisms in Florida soils; metabolism and functional relationships of soil micro-organisms under Florida

conditions; interrelationships of microbiological action in soils and cropping systems in Florida; the availability of calcium and phosphorus of colloidal phosphate applied to soils adapted to pasture; adjustment of reaction of Florida soils; factors determining the toxic limits of calcium cyanamide; nitrogen supply and deficiencies of trace elements; soil correlations; soil fertility investigations under field and greenhouse conditions; water control investigations; crop rotation studies; studies upon the role of special elements in plant development upon the peat and muck soils of the Everglades; and sweetpotato fertilizer and storage experiments.

[Soil investigations by the Kentucky Station] (*Kentucky Sta. Rpt. 1941*, pp. 6-9, 47).—These include work on the effect of cropping and manure treatments on amount of nitrogen in soil, phosphorus compounds in Kentucky soils, manure as a source of potash, effect of excessive liming on yield and quality of crops, pastures—effect of different fertilizer treatments on phosphorus and calcium content of herbage, tests for need of the minor elements in soils, and control of soil erosion on steep land.

[Soil investigations by the Massachusetts Station] (*Massachusetts Sta. Bul. 388 (1942)*, pp. 10-11, 12, 19, 31-34, 53, pl. 1).—Soil conservation research projects on wind-blown soils and topsoil removal and experimentation with historical "soil-test plats" are reported upon by K. J. Kucinski and W. S. Eisenmenger; nature of soil erosion in Massachusetts, by A. B. Beaumont and Kucinski; lowering of pH by soil nitrates, by R. W. Donaldson, Eisenmenger, and H. M. Yeglan; the effect of arsenious, arsenic, and antimony oxides on soil and plant growth, by Eisenmenger and Yeglan; nitrification in soils containing plant residues of high lignin content, by J. E. Fuller; the influence of base exchange capacity and of exchangeable ions in Massachusetts soils on the availability of potassium, the relationship of base exchange capacity, exchangeable hydrogen, and soil reaction to the lime requirement of Massachusetts soils, and the fixation of arsenic in soils and the influence of arsenic compounds on the liberation of fixed phosphates, all by D. H. Sieling; and the effect of orchard mulches on the plant nutrient elements in the soil, by Sieling and J. K. Shaw.

[Soil investigations by the New Jersey Stations] (*New Jersey Sta. Rpt. 1941*, pp. 77-78).—Line 14 of the abstract previously presented under this title (E. S. R., 87, p. 342) should read as follows: The soil conservation program is not too complicated for use on the average New Jersey farm.

Soils of Golden Valley County: Soil reconnaissance of Montana—Preliminary report, L. F. GIESEKER. (Coop. U. S. D. A.). (*Montana Sta. Bul. 403 (1942)*, pp. 51, fig. 1, maps 4).—This survey, similar in scope and method to those previously noted (E. S. R., 82, p. 306), deals with an area contained in the Musselshell River Drainage Basin between the Big Snowy Mountains and the Musselshell-Yellowstone River Divide. It covers 1,216 sq. miles.

A petrographic method for the study of soil formation processes, C. E. MARSHALL. (Mo. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 100-103).—The author points out and illustrates the great "aid which petrological methods can render, first in deciding questions of origin and second in enabling us to form a clearer picture of soil-forming processes." Neither chemical nor mechanical analysis has proved sufficient to decide the most difficult cases.

The development of loessial soils in central United States as it reflects differences in climate, H. B. VANDERFORD and W. A. ALBRECHT (*Missouri Sta. Res. Bul. 345 (1942)*, pp. 31, figs. 5).—The loessial soils along river bluffs of the central United States were studied, all factors of soil development, except climate, being as nearly constant as is possible under natural conditions. Quantitative measurements of the size distribution of particles in the profiles, the nature of the clay, the exchangeable bases, the organic content of the

surface layers, and the mineralogical make-up of the silt fraction were used as indices of developmental differences in the soil profiles. Many aspects of soil properties under different climatic conditions in their relation to soil development are brought together.

The clay content increased with the rainfall and temperature, and the nature of the clay also changed. The exchangeable bases in the soil decreased as the climatic conditions became more humid and warmer. The organic matter and nitrogen contents of the surface layers decreased as the temperature increased. Study of the silt fraction indicated that the parent material was constant for all locations and that the solum had undergone changes corresponding with the intensity of the climatic conditions.

Soluble material of soils in relation to their classification and general fertility. M. S. ANDERSON, M. G. KEYES, and G. W. CROMER (*U. S. Dept. Agr., Tech. Bul. 813 (1942), pp. 79, figs. 12*).—The studies here reported include comparisons of soil solutions variously prepared from representative series of some of the important great soil groups and of base-exchange relationships of these same soils. Data upon the relation between soil solutions and plant response to alteration of the water-soluble components, after alteration of important soil types has taken place through cultural practice, are also presented. Following an outline of the plan of work, the bulletin gives a description of the virgin soils studied and takes up factors affecting solubility of virgin soils, electrical-conductivity measurements, chemical composition of soil solutions variously prepared from virgin soils, soluble material in relation to depth in a soil profile, interrelationships of constituents, soluble material in cultivated soils in relation to crop growth, relation between total chemical composition of soil and the water solution, and soil solution as a medium for plant growth. Soils of the Podzol, Chernozem, Prairie, Gray-Brown Podzolic, lateritic, and Red Podzolic groups were investigated and are reported upon in detail both qualitatively and in terms of tabulated numerical data.

Effect of drought and rainfall on movement of soil nitrogen in Cecil soils. E. D. MATTHEWS (*Georgia Sta. Cir. 137 (1942), pp. 7*).—Experiments here briefly described indicated the following:

- Prolonged dry weather, which completely dries the upper few inches of soil, causes most of the soil nitrates to come to or near the soil surface. Nitrates in the surface soil during dry weather are not available to crops and may be lost by sudden hard rains causing runoff, or by blowing, particularly if stock is allowed to trample or root. Neither ordinary showers nor heavy rains cause any appreciable leaching of nitrate on Cecil sandy loam soils. Continued showers remove more nitrate from the surface to lower depths than other types of rain, but even they may not cause much nitrate to be lost unless rains continue for long periods. In dry weather nearly all of the nitrate and ammonia nitrogen is in the top foot of soil, regardless of what source of nitrogen is used. When rainfall is sufficient to cause much downward movement of soil nitrogen, nitrate nitrogen is more readily leached than ammonia nitrogen. However, the leaching of nitrate nitrogen bears no relationship to the nitrogen fertilizer used. The leaching of ammonia nitrogen is small, and the more ammonia nitrogen furnished by the fertilizer the less leaching of both ammonia nitrogen and nitrate plus ammonia nitrogen.

The determination of pH at soil moisture contents approximating field conditions. H. D. CHAPMAN, J. H. AXLEY, and D. S. CURTIS. (*Calif. Citrus Expt. Sta.*). (*Soil Sci. Soc. Amer. Proc., 5 (1940), pp. 191-200*).—With the Beckman type glass electrode equipment, pH readings on soils at moisture contents as low as that of the air-dry state can be obtained. However, with

air-dry soils the readings rapidly drift and bear little resemblance to those obtained when the moisture is somewhat higher. At moisture contents corresponding to the moisture equivalent, stable readings may be obtained provided the electrodes are worked around or in and out of the soil prior to taking the reading. Imperfect coverage of the glass electrode with the soil moisture film will give erratic, unreliable values. Reasonably stable and reproducible pH readings can be obtained with soils at the sticky point or beyond. Tests on some 50 widely different soils at moisture contents corresponding to and on either side of the sticky point gave results of such constancy and consistency as to suggest the suitability of such a method for pH determinations on soils generally. Considerable differences in moisture content in this general range had but little effect on the pH value. In all the soils studied, pH values on 1:2.5 water suspensions were significantly higher than those on soils at moisture contents characteristic of possible field conditions. The pII values obtained immediately after wetting the soil to the sticky point or higher were not significantly different from those obtained after the soils had stood in the moist state at room temperature for several hours or days. Average values for in situ readings were little different from those obtained when the soil was removed to a beaker. There was considerable variation between readings made at different points in an area, however.

Redox potentials of desert soils under varying conditions of sterilization, aeration, and puddling. T. F. BUEHRER, W. P. MARTIN, and B. P. CARDON. (Univ. Ariz.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), p. 241).—This investigation was part of a general study of the effect of puddling on soil fertility.

Measurement of redox potentials under N_2 or storing soil samples under nitrogen before measurement of the redox potential, invariably leads to erroneous results. Furthermore, there exists a "suspensions-effect" in redox measurements similar to that observed in pH determinations, making it necessary that the soil be kept continuously in suspension during the course of measurement. Vigorous mechanical stirring in air was found to be most conducive to reproducibility in the redox potential measurements.

The relation of soil temperature to soil moisture: Pressure potential, retention, and infiltration rate. R. E. MOORE. (Univ. Calif.) (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 61-64, figs. 4).—The pressure potentials and water retention after suction were determined both in soils which had been moist for a long time and in soils saturated for 24 hr. only. The maxima and minima in the curves suggest that temperature as such may be of minor importance in determining the pressure potential or water retentions resulting from these experimental conditions, but that other factors are involved, the effects of which may be influenced by the course and magnitude of temperature change and the duration of a given temperature range. In experiments on water retention after irrigation and on infiltration rate air-dry soils were used, and the major water percolation and distribution took place before the soil was completely slaked. Under these conditions the opportunity for factors other than temperature and viscosity to develop effects was minimized. The gross trends of the curves indicate effects due to viscosity, but maxima in portions of the curves suggest that factors other than viscosity affected the properties of soil moisture retention and percolation.

Soil moisture and plant growth in relation to pF. C. M. WOODRUFF. (Mo. Expt. Sta.) (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 36-41, figs. 8).—A number of tentative conclusions as to the state, retention, and movement of moisture in soils are set forth. Among the experimental results noted is the observation that a pF value near 3.0 is of fundamental importance in that it represents the

maximum quantity of water that a soil will hold against the force of gravity or as a result of capillary movement to regions of lower moisture content resulting from evaporation or plant use. pF 3 defines the smallest size of pore that will function as a capillary for the free movement of water. The moisture held above pF 4.1 to 4.2 is not available to plants. In most instances the principal supply of water for plants is held between pF 3.0 and 4.1. The volume of the soil pore space required to accommodate moisture held above pF 3 may be so great as to exclude the minimum amount of air required for plant root development. The adsorbed moisture in a soil surrounds each particle preventing contact with other particles. Loss of adsorbed water causes shrinkage which increases the capillarity of the soil until it becomes rehydrated. The capacity of the soil as a reservoir for absorbing rain and as a reservoir for supplying water for plant growth is governed by both the adsorptive capacity below pF 4.1 and the depth to which plant roots penetrate.

Concerning permeability units for soils, L. A. RICHARDS. (U. S. D. A.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 49-53, figs. 2).—A permeability unit acceptable for general use in different lines of work must be based on a flow equation which is adequate to cover a variety of flow cases. The equation

$$v = \frac{k}{\eta} (\rho F - \nabla p) \equiv \frac{k}{\eta} \rho g i$$
 seems to have certain advantages. In this equation i is the hydraulic gradient, v is the volume of water crossing unit area in the soil in unit time, and k is the Darcy coefficient of permeability. The quantity ρ is the density, F the body force per unit mass, p the pressure, η the viscosity, and ∇ the gradient operator. For soil moisture flow, F represents the gravity force and is numerically equal to the acceleration of gravity, g . "The k in this equation could be referred to as the cgs unit of permeability, or in view of the various meanings associated with permeability it might be desirable from analogy with the treatment of thermal and electrical flow in physics to designate this k as 'fluid conductivity.' There is precedence for such a name in the literature of both soil science and engineering."

Adsorbed ions on the colloidal complex and plant nutrition, W. A. ALBRECHT. (Mo. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 8-16, figs. 14).—The inadequacy of the soil solution as an explanation of the supply of nutrients to the plant from the soil is pointed out, and the part played by the clay colloids as a storage reservoir of nutrient ions and inactivator of toxic ions is discussed. An experiment in which clay colloid containing calcium as its only adsorbed nutrient ion gave much better growth than did potassium or magnesium clays is briefly described. The possibility of nutrient movement from plant root to soil colloid as well as from soil to plant is also taken up, together with the relation of calcium movement to degree of clay saturation with that element, movements of plant nutrients from plant to soil under conditions of calcium deficiency, etc.

Plant composition as an index of soil fertility, F. MOSER. (S. C. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 147-151).—The nutrient content as determined by plant analysis for certain critical elements absorbed by plants at maximum growth is suggested as an index of fertilizer requirements for lateritic soils. Pot experiments on Cecil sandy loam show that lespedeza and Austrian Winter peas make their optimum growth at pH ranges of from 6.0 to 6.5, while the deleterious effect of low pH values can best be offset with liberal phosphate application. For good quality hay and for best production, both limestone and superphosphate are recommended.

The effect of substituted cations in the soil complex on the decomposition of organic matter, F. B. SMITH and T. WHITEHEAD, Jr. (Fla. Expt. Sta.).

(*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 248-253, figs. 4).—The authors electrolyzed Tama silt loam (an Iowa soil) in a Mattson cell (E. S. R., 56, p. 115) and either resaturated with calcium, magnesium, or ammonium ions or mixed the calcium-saturated soil with various proportions of hydrogen-saturated soil. Bentonite clay was similarly treated. A barium bentonite was also prepared. The rates of decomposition of various forms of organic matter in the soil and in mixtures of the clay with sand were determined in terms of the carbon dioxide produced. Green sweetclover in Tama silt loam showed the least decomposition rate in the hydrogen-saturated soil, a much greater decomposition in the calcium-saturated soil, somewhat more in the original soil and in the ammonium-saturated soil than in the calcium-saturated, and decidedly more in the magnesium-saturated soil than in any of the preceding. Natal grass in barium, calcium, and magnesium bentonites mixed with sand showed the greatest decomposition in the presence of the calcium-saturated clay at all sand-clay proportions. At the proportion providing 4.92 milliequivalents of the base, or 8.20 m. e., more decomposition was shown in the barium than in the magnesium clay, but with 11.48 or 16.40 m. e. of the base present the decomposition was greater in the magnesium than in the barium clay mixtures. Effects of percentage of saturation with the base and numerous other related observations are also recorded.

Evidence of the limited importance of soil bacteria as a direct factor in the aggregation of Prairie soils, H. E. MYERS, T. M. MCCALLA, and H. E. JONES. (Kans. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), p. 254).—The data indicate that bacteria are associated with and responsible for the aggregation of soil particles only insofar as they are responsible for the accumulation of certain metabolic products that function as cementing materials. Changes in H-ion concentration as a result of the decomposition of added organic materials were not concomitant with changes in aggregation. Adjustment of the pH of soils within the approximate limits of from 4.1 to 6.7 did not significantly influence the stability of preformed aggregates. No tendency of calcium to improve the stability of aggregates was observed. The addition of water to pulverized air-dry soil caused a very sharp and rapid increase in the percentage of water-stable aggregates. This increase occurred in sterilized soils, hence is independent of microbial activity.

Influence of microbial activity upon aggregation and erodibility of lateritic soils, T. C. PEELE and O. W. BEALE. (U. S. D. A. coop. S. C. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 33-35).—The aggregation of Cecil sandy loam was greatly improved through the activity of certain species of fungi (especially *Penicillium oxalicum* and *Fusarium moniliforme*) and bacteria under aseptic conditions. The addition of sucrose plus inoculation with *P. oxalicum* to field plats on Cecil sandy loam caused an increase in aggregation and a decrease in runoff and erosion. The increased aggregation was attributed to microbial activity and the decreased runoff and erosion to the increased aggregation. In pots of this soil ground oat straw with the same inocula also increased aggregation.

Soil bacteria may solve shortage, J. E. CONN (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, p. 16).—A shortage of the indicator litmus has developed since the German invasion of the Netherlands where litmus was prepared from lichens which were imported from the Dutch Colonies. In attempting to overcome this shortage it was discovered at the station that a certain kind of soil bacteria produces a substance surprisingly like litmus. The pigment produced, however, is not entirely satisfactory, and further research is necessary.

A fixation method for determining the phosphorus and potassium requirements of soils, E. R. PUEVIS and J. M. BLUME. (Va. Truck Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 201-204).—Laboratory and field data are presented to show the relationship existing between the amount of phosphorus and potassium absorbed by a soil from a standard solution and the response of various crops to fertilization of the soil with these elements. An absorption method for determining the phosphorus and potassium requirements of soils is described.

Efficient use of manure patriotic duty as well as good business on Colorado land, R. GARDNER (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 3, pp. 8-10, fig. 1).—A discussion of the importance of utilizing manure as efficiently as possible during the emergency period because of the need of the war industries for some of the chemicals used in the manufacture of commercial fertilizers.

Fertilizers other than nitrogen for cotton in the Delta, R. KUYKENDALL (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 7, p. 2).—The development of fertilizer use and response under delta soil conditions in Mississippi is discussed. Based on tests from various areas, it has been found that there are conditions under which phosphorus and potash are needed for maximum crop production.

Soil and crop interrelations of various nitrogenous fertilizers: Windsor lysimeter series B, M. F. MORGAN and H. G. M. JACOBSON (*Connecticut [New Haven] Sta. Bul.* 458 (1942), pp. 269-328, figs. 2).—Fifteen nitrogen carriers were compared in outdoor lysimeter tanks filled with Merrimac sandy loam, with tobacco as the indicator crop. The soil was placed in the lysimeters in successive fillings of mixed and carefully packed soil so as to be representative of the soil profile under field conditions. Ten yr. of nitrogen treatment are reported and also 1 yr. of no treatment to show the residual effects. The nitrogen carriers investigated were sodium nitrate, potassium nitrate, calcium nitrate, ammonium sulfate, Ammo-Phos, urea, Calurea, cyanamide, cottonseed meal, castor pomace, linseed meal, fish meal, dried blood, tankage, and cow manure. The plants grown, as well as the leachate obtained, were analyzed to determine differences in amounts and rates of available nitrogen liberation in the soil. Data are given on the total nitrogen removed by the crop, unit composition of the crop, nitrogen represented in the drainage water in successive periods of leaching, the residual nitrogen after 10 yr. of treatment as measured by crop and leaching, and nitrogen content of the soil at the end of the experiment, in comparison with the initial amount. Detailed statements are also presented on the characteristics of the various fertilizer materials used.

Catalytic activity causing the hydrolysis of urea in soils as influenced by several agronomic factors, J. P. CONRAD. (Univ. Calif.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 238-241, figs. 4).—Each subsample of 400 gm., mixed with about 10 cc. of toluene, was placed in its respective percolator. Toluene in excess of saturation was added to each urea solution in preparation for percolation. The percolators were maintained at approximately 30° C. Enough solution, varying from about 100 to 160 cc., was added to wet the soil initially and bring it to the verge of dripping. Every 12 hr. thereafter until the end of the test 75 cc. of the same concentration of solution was added. The residual urea in successive percolates caught was determined. Two types of catalytic activity were in evidence, viz, a nearly constant activity and a rising activity. In some soils the rise was very rapid. Samples of deep mineral subsoils showed little activity, generally nearly constant, or no activity. Activities at higher levels in the profile were generally progressively greater. They were generally of a

nearly constant or slowly rising type. The activities of the surface soil samples were the highest of their respective profiles and were often of a rapidly rising type. Cropping and cultural practices which added organic matter to the soil usually resulted in high activities and frequent cases of a rapidly rising type, especially in the surface soil. Practices which tend to deplete organic matter resulted in a lower and a more nearly constant activity.

The response to magnesium of six different crops on sixteen Alabama soils, A. L. SOMMER, J. I. WEAR, and A. BAXTER. (Ala. Expt. Sta.). (*Soil Sci. Soc. Amer. Proc.*, 5 (1940), pp. 205-212, figs. 2).—Of the crops grown, corn (vegetative stage only) responded least and crotalaria and peanuts (yield of nuts) most to magnesium sulfate in greenhouse tests. Cotton and crimson clover gave considerable response and turnips relatively little. Of the general soil types considered, the Norfolk sands and sandy loams were most deficient in magnesium. A decrease in the magnesium content of some of the soils was shown by the difference in response to magnesium fertilization of the two corn and of the two turnip crops, as well as by soil analyses at the beginning and end of the experiment. The magnesium content in Chilean sodium nitrate and in potassium chloride was sufficient to benefit only corn. Superphosphate furnished sufficient magnesium for the growth of all crops except crotalaria and peanuts grown in the most deficient soils. A correlation whereby crop response could be predicted from the magnesium content of the soil was not found.

✓An easier, more effective method of applying fertilizers, C. B. SAYRE (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, pp. 8-10 figs. 4).—Methods of applying fertilizer that will produce satisfactory crop yields and reduce the amount of labor required are of special importance during the emergency period when labor is one of the essential factors in meeting the food production goals. Fertilizer placement in relation to the crop being produced has been shown to have a considerable effect on the yield. In this article reporting a comparative study of recent methods of applying fertilizers, plowing under is reported by the author to have the following advantages: (1) Labor is saved since the fertilizer is applied while plowing; (2) fertilizer placed in an area accessible to the roots can be more effectively used by the crop to increase yields; (3) it avoids burning injury; (4) the rush of work at planting time is avoided by applying the fertilizer with plowing; and (5) plants are enabled to continue growth during drought periods with deep placement of fertilizer.

Commercial fertilizers in Kentucky in 1941, J. D. TURNER, H. R. ALLEN and L. GAULT (*Kentucky Sta. Regulat. Ser. Bul. 30* (1942), pp. 63).—In addition to the results of inspection and analyses of commercial fertilizers sold in Kentucky, this publication contains a timely discussion on low-grade fertilizers, as well as information on the use of fertilizers for maximum production during the emergency.

Registration, labeling, and inspection of commercial fertilizers, 1941, M. F. MILLER, L. D. HAIGH, E. W. COWAN, and V. B. WILLIAMS (*Missouri Sta. Bul. 449* (1942), pp. 52).—This bulletin consists of the usual annual report of analyses and compliance of commercial fertilizers with the State law.

AGRICULTURAL BOTANY

[Botanical studies by the Massachusetts Station] (*Massachusetts Sta. Bul. 388* (1942), pp. 28-29).—Brief progress reports are given by L. H. Jones, J. W. Hall, and B. Eames on the effect of soil temperature on growth of corn, tomato, and rose used as indicator plants; and the effect of root media on root structure of soybean and corn plants and of geranium and chrysanthemum cuttings.

Lehrbuch der Botanik für Hochschulen [Eduard Strasburger's college textbook of botany], edited by H. FITTING, H. SIERP, R. HARDER, and F. FIEBAS (Jena: Gustav Fischer, 1942, 21. ed., pp. XII+626, pl. 1, figs. 846).—Other editions of this book have been noted (E. S. R., 67, p. 20).

Den Danske Botaniske Litteratur, 1912-1939 [Danish botanical literature, 1912-1939], C. CHRISTENSEN (København (Copenhagen): Ejnar Munksgaard, 1940, pp. [6]+350, [figs. 78]).—The bibliographies are arranged by authors, and an author index is provided. Portraits of 78 botanists are included.

Some proposals for the war-time use of plankton, N. POLUNIN (*Chron. Bot.*, 7 (1942), No. 3, pp. 133-135).—This is a brief review of the literature on possible uses of plankton for human or animal food and for plant nutrition.

Ageing without reproduction and the viability of young bacterial cells at low temperatures, J. M. SHEERMAN and H. B. NAYLOR (Cornell Univ.) (*Jour. Bact.*, 43 (1942), No. 6, pp. 749-756).—*Escherichia coli* and *Streptococcus lactis* were studied at 1° C.

A new type of glucose fermentation by *Clostridium thermoaceticum* n. sp., F. E. FONTAINE, W. H. PETERSON, E. MCCOY, M. J. JOHNSON, and G. J. RITTER (Wis. Expt. Sta. coop. U. S. D. A.). (*Jour. Bact.*, 43 (1942), No. 6, pp. 701-715, fig. 1).—In the fermentation of glucose by *C. thermoaceticum* n. sp., 85 percent of the carbon in the glucose destroyed is recovered as acetic acid.

The lactic acid fermentation of streptococci, P. A. SMITH and J. M. SHEERMAN (Cornell Univ.). (*Jour. Bact.*, 43 (1942), No. 6, pp. 725-731).—The lactic acid production of the better known species of streptococci (pyogenic, viridans, lactic, and enterococcic groups) was studied by methods described and is discussed. The average percentage of lactic acid from glucose fermented for each species is given.

Mycological nomenclature, G. R. BISBY (*Phytopathology*, 32 (1942), No. 7, pp. 644-645).—Formal consideration is requested for two changes in the International Rules of Botanical Nomenclature with respect to fungi.

On the primary dispersal and isolation of fungal spores, C. G. DOBBS (*New Phytol.*, 41 (1942), No. 1, pp. 63-69, fig. 1).—A distinction is drawn between active and passive, primary and secondary, spore dispersal, and a tentative grouping of passive primary dispersal types is outlined, in the order of increasing importance of air and decreasing importance of water. A majority of fungi tested in air were found to be spore shedders, a minority spore retainers. It is pointed out that previously all methods of spore isolation have made use of water as the primary dispersal medium, and a simple method of isolation by air is described.

The role of isolation in the differentiation of plant species, G. L. STEBBINS, JR. (In *Biological Symposia*, VI, edited by J. CATTELL. Lancaster, Pa.; Jacques Cattell Press, 1942, vol. 6, pp. 217-233).

Determination of correct scientific names of common plants (Arizona Sta. Rpt. 1941, pp. 48-49).—Brief notes are given on the nomenclature of the screwbean, California poppy, and cockroach plant.

Anatomical and taxonomic approaches to subgeneric segregation in American *Quercus*, A. H. TILSON and C. H. MULLER (U. S. D. A.) (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 523-529, figs. 9).—A study of the wood anatomy of 104 species of American oaks in comparison with the conventional taxonomic characters led to the conclusion that the former does not constitute a basis for subgeneric division and only roughly indicates a possible division of the white oak subgenus into sections. There are 18 references.

The red oak complex in the United States, E. J. PALMER (*Amer. Midland Nat.*, 27 (1942), No. 3, pp. 732-740, figs. 2).—A taxonomic study of this group of

the genus *Quercus*, with a key to the five species and several varieties. There are 14 references.

Quercus macrocarpa in Alabama, R. M. HARPER (*Jour. Elisha Mitchell Sci. Soc.*, 58 (1942), No. 1, pp. 60-64, pl. 1, fig. 1).—Notes on the distribution and seedling stages and variability of this oak.

The relationship of *Ranunculus* to the North American floras, L. BENSON. (Ariz. Expt. Sta.). (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 491-500, figs. 2).—This paper presents the broad outlines of the geographical distribution of the genus which have emerged as a result of monographing the group for North America north of Mexico and as a result of collecting 11,000 plant specimens, including several hundred sheets of *Ranunculus*, in the field. Combined with an interpretation of the distribution of the genus is an attempt to classify the many vegetation areas with which it is associated and to point out the significance of *Ranunculus* in defining major floristic areas and in determining the possible origin and relationships of the North American complex of floras. There are 24 references.

Sinopsis de la flora del Cuzco.—I, Parte sistemática [Synopsis of the flora of Cuzco.—I, Systematic part]. F. L. HERRERA (*Lima, Peru: Govt.*, 1941, vol. 1, pp. 528, [pl. 1, figs. 13]).—This taxonomic synopsis includes the cryptogams, bryophytes, pteridophytes, and flowering plants.

New grasses from Venezuela, Z. LUCES (*Jour. Wash. Acad. Sci.*, 32 (1942), No. 6, pp. 157-166, figs. 10).—Ten new species and one new combination are included.

New bamboos from Venezuela and Colombia, F. A. McCURE (*Jour. Wash. Acad. Sci.*, 32 (1942), No. 6, pp. 167-183, figs. 8).—Seven new species, one new combination, and one new genus (*Elytostachys*) are included.

Zur Kenntnis der Mykorrhizabildner von Kiefer und Fichte [The mycorrhizas of pine and spruce], O. MODERS (*Symb. Bot. Upsal.*, 5 (1941), No. 1, pp. 147, pls. 3, figs. 27).—A monographic study, with bibliography and index to the fungi concerned.

Oxidation and assimilation of glucose by the root nodule bacteria, R. H. BURRIS and P. W. WILSON. (Univ. Wis.). (*Jour. Cell. and Compar. Physiol.*, 19 (1942), No. 3, pp. 361-371, figs. 5).—Increased oxidation of glucose by a strain of *Rhizobium trifolii* from the action of 2,4-dinitrophenol could be induced either by adding it initially or after assimilation of glucose was complete. Hence, with the *Rhizobiums* it is unnecessary to postulate an inhibition of assimilation to explain the increased substrate oxidation. Oxidation of the storage products of the cells, probably gums, was stimulated by the presence of $m/10,000$ dinitrophenol. Glucose in the presence of washed *Rhizobium* cells grown on a yeast-extract medium without added carbohydrate disappeared when oxidation was far from complete. Strains vary in their ability to oxidize and assimilate glucose. Washed cells of another strain, even when grown in the presence of sugar and relatively low in N, gave no more than one-fourth complete oxidation of glucose in the absence of dinitrophenol. The low percentage oxidation of glucose by cells grown on the yeast-extract medium is thus not necessarily attributable to their high N content.

Influence of aeration and soil temperature on the development of inoculated and noninoculated soya plants, M. M. GUKOVA and W. S. BUTKEVICH (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 31 (1941), No. 9, pp. 937-940, figs. 3).—In some cases the yield of legumes was increased not only by additions of N to the soil but also by creating more favorable conditions of aeration and temperature for the activity of the nodule bacteria. It is believed probable that in these more congenial conditions for N fixation lies the reason

why in certain reported studies the products of N fixation were observed to pass into the surrounding medium.

Growth of *Rhizopus suinus* as affected by certain growth factors, C. L. WORLEY. (Univ. Ga.). (*Plant Physiol.*, 17 (1942), No. 2, pp. 278-288).—The hitherto reported effects of yeast extracts on *R. suinus* have been diverse and contradictory. In general, the author's preliminary tests indicated that yeast itself (or accompanying portions of the cake) contains water-soluble stimulators and inhibitors, the latter being removable by adsorption on Nuchar-W or by solution in 95 percent ethanol. Results with tests of thiamin, mesoinositol, and biotin tended to suggest the possibility that the stimulant in yeast extract may be one or both of the first two, and that the inhibitor is not a component of bios but rather an unknown, or possibly heteroauxin. Since a parallelism existed between the effects on growth and on asexual reproduction for all tests with yeast extracts and synthetic bios components, these factors affect the fruiting only indirectly through altered vegetative growth. Liver infusion and urine both gave marked positive results, in agreement with those obtained on other fungus species. *Rhizopus* filtrate (substance-B) showed the presence of a biologically produced growth factor effective not only on other fungus species as previously shown, but also on the growth and asexual reproduction of *R. suinus* itself.

Comparative growth studies on a proliferation-promoting extract from ultraviolet injured yeast cells, known bios components and amino acids, E. S. COOK and A. G. CRONIN (*Studies Inst. Divi Thomae, Athenaeum Ohio*, 3 (1941), No. 1, pp. 205-222, fig. 1).—The ability of cell-free filtrates from ultraviolet injured yeast cells (crude "wound hormone" preparations) to stimulate proliferation of *Saccharomyces cerevisiae* was studied in Reader's and Williams' media with and without adding known bios components (inositol, thiamin, biotin, pantothenic acid, and vitamin B₆) and 20 amino acids. A significant portion of the growth activity proved due to these known factors, but a definite part of the potency was found ascribable to other material or materials. The possible relationship of nucleic acidlike substances, selectively absorbing ultraviolet at about 2,600 a. u., to the wound hormones is discussed. The amino acids and the bios components (except thiamin) for the most part exerted slight effects or none on yeast respiration, and the wound hormone preparations caused only a 25 percent stimulation at concentrations of 0.5-1 mg. per cubic centimeter. There are 30 references.

The estimation, isolation, and identification of auxins in plant materials, A. J. HAAGEN-SMIT, W. D. LEECH, and W. R. BERGREN (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 500-506, fig. 1).—A technic comparable in completeness of auxin extraction to the in vivo biological digestion method is described as being a hydrolysis at pH 10.5 for 48 hr. at room temperature. Isolation of the auxin extracted from corn meal by this procedure yielded crystals melting at 164°-165° C., identified as indole-3-acetic acid. Pseudo-auxin *a* was isolated from the hydrolyzed corn meal, indicating the presence of auxin *a* in the original material. There are 24 references.

Interactions of auxins in growth and inhibition, F. SKOOG, C. L. SCHNEIDER, and P. MALAN (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 568-576, figs. 4).—Studying the effects on growth of indole-3-acetic and γ -phenylbutyric acids supplied separately and in mixtures by various standard methods in the oats coleoptile, the results showed that phenylbutyric acid might possess slight auxin activity, but when administered with indolebutyric acid its main effect was to inhibit the activity of the latter. The extent of this inhibition was a function of the relative concentrations of the two substances and is therefore ascribed to competitive action between them. Phenylbutyric acid in solutions or plant tissues

prevents quantitative estimations of their auxin activity (plant auxin or indoleacetic acid), and it cannot be effectively eliminated for analytical purposes by ether extraction, diffusion in agar blocks, or transport through plant tissues. Phenylbutyric acid does not possess the properties implied in the definition of a "hemiauxin." The increase in response to indoleacetic acid elicited in its presence under certain conditions is attributed to an acid effect or a slight auxin activity of high concentrations of phenylbutyric acid and its "sparing" action, especially on low concentrations of indoleacetic acid. The results conform to the view that auxin acts as a coenzyme. On this basis a scheme is presented for the action of auxins in growth stimulation and inhibition which affixes an important determinative role also to interactions between auxin and its enzyme substrate complex. It thus provides for the contribution of formative effects from the cell environment and nutrients, and avoids ascribing separate kinds of activity to different auxins to account for discrepancies in the types of response produced. Hence it emphasizes the immediate regulatory or correlative action of auxin in the growth process, and accounts for the ability of auxin to accelerate or inhibit growth as a quantitative manifestation of a single function rather than as the results of separate qualitative effects. There are 34 references.

Growth, auxin, and tropisms in decapitated *Avena* coleoptiles, F. W. WENT (*Plant. Physiol.*, 17 (1942), No. 2, pp. 236-249, figs. 3).—When oats coleoptiles were decapitated and at 0.5-1 hr. intervals a number of their properties measured, it was found that after decapitation the auxin content as determined by ether extraction slowly fell off to 50 percent after 2 hr. and then increased again. A similar curve was noted for growth rate, though the decrease was larger and especially after 2 hr. It is concluded that the growth rate is due to the amount of extractable auxin in the tissues. For diffusible auxin from the various coleoptile zones, immediately after decapitation only small and decreasing amounts of precursor could be collected from any part of the coleoptile, and no auxin, but after 2 hr. auxin production again became evident in the apical section. An almost identical behavior was found for geotropism and phototropism. It is concluded that geotropism curvature is due to an effect of gravity on the diffusible auxin. This work is said also to confirm the thesis that regeneration of the auxin production 2-3 hr. after decapitation accounts for the reappearance of geotropic and phototropic sensitivity and increased growth rate. There are 15 references.

Control of flowering with phytohormones, H. E. CLARK and K. R. KERNS. (Univ. Hawaii). (*Science*, 95 (1942), No. 2473, pp. 536-537).—By use of appropriate concentrations of certain synthetic growth substances, including α -naphthaleneacetic acid, naphthaleneacetamide, naphthalenethioacetamide, and a commercial product Fruitone, flowering in pineapple was induced in advance of the normal period or delayed until much later. Since the differentiation of the inflorescence itself was initiated, the results differed from earlier uses of the same or similar phytohormones in producing parthenocarpic fruits, hastening of flowering by seed treatments accelerating growth, or premature flowering of tobacco said to be due to hastening of the terminal growth after the flower buds had formed.

The distribution of auxins in bulbs of *Lilium longiflorum*, W. S. STEWART and N. W. STUART. (U. S. D. A.). (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 529-532, figs. 4).—Large differences in relative amounts of auxin were found in different parts of Easter lily bulbs on November 13, 4½ mo. after harvest and after storage in moist peat moss at 70°-85° F. The apical 3 mm. of the stem axis contained about 1,000 times the concentration present in the scales and basal

plate. The rest of the stem contained one-fifth the relative amount in the apical meristem. During subsequent storage (November 13 to December 15) at 77° and with sufficient moisture for active growth, there was a continual decrease of auxin in the scales and stem. In the basal plate and stem tip there was an initial decrease followed by a definite increase of auxin. The possible relationships between auxin changes and growth responses of the bulbs are discussed.

Effects of fluorescein on plant growth, J. and H. SELLEI, A. MAYER, and F. W. WENT (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 513-522, figs. 3).—The work here reported with beet, bean, marigold, and tomato confirms earlier studies (E. S. R., 86, p. 753), in which fluorescein was found to increase plant growth when applied at low concentrations and to inhibit it at high concentrations. Plants treated with low concentrations responded by producing heavier tops and roots and more fruits, and also by showing a qualitative improvement. Sand culture tests showed practically the same percentage increase as those carried out in plats in heavy adobe soil, indicating that the effect of fluorescein is general and not restricted to one kind of soil. Sand culture tests of short duration in the greenhouse and darkroom, when giving fluorescein of high and low concentrations to young tomato plants, showed that a definite acceleration or inhibition of stem elongation was evident within 3 days. A possible explanation of the mechanism of fluorescein action is discussed. There are 19 references.

Studies in pollen tube culture, W. A. BECK and R. A. JOLY (*Studies Inst. Divi Thomae, Athenaeum Ohio*, 3 (1941), No. 1, pp. 81-101).—In 2 years' artificial culture of pollens of over 125 species of monocotyledons and 50 of dicotyledons, a semisolid medium of agar containing 10 percent sucrose and a trace of yeast proved most favorable to optimum growth among those tried. Growth substances and vital stains were most effective when incorporated in the medium, and neutral red and methylene blue were the most favorable stains. Pollens from monocotyledons gave better results than those from dicotyledons, and pollens of the Liliaceae were best, though those from Amaryllidaceae were also good. Liliaceous pollen is large, remains viable for months, and carries a considerable amount of volatile oil which is of growth-promoting nature or serves as a vehicle for growth substances. The tubes, which develop quickly and vigorously, have a considerable diameter and are particularly well adapted for testing the physiological effectiveness of auxins. The pollens of *Hymenocallis* and *Amaryllis* were especially suited to studying development of the generative cell and hence are to be recommended for investigating bios factors. There are 28 references.

Plants' content of minor growth substances as affected by vernalization and photoperiodism, L. P. ŽDANOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 32 (1941), No. 8, pp. 584-587).—From data obtained in photoperiod tests with short- and long-day plants (seven widely separated species) and vernalization tests with winter and spring wheat, it is concluded that the content in minor growth substances (bios and ascorbic acid) in plants increases with the intensity of the growth processes and is not connected with transition to the reproductive phase.

Role of the invertase in the synthesis of starch by the vegetable cell, B. A. RUBIN and E. V. АЕТЗИКHOVSKAYA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 31 (1941), No. 7, pp. 675-678).—The authors conclude from their studies that the two indispensable conditions for starch formation in a living cell are a sufficiently active amylase and an adequate amount of sucrose, which in turn is a product of the synthetic activity of invertase. It is believed that the rôle played by sucrose in building up starch gives grounds for classing invertase among the most important regulators of carbohydrate metabolism in the plant cell.

Influence of temperature alternation on the germinable power of hop seeds (*Humulus lupulus* L.), I. N. HOLUBINSKY (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 32 (1941), No. 1, pp. 85-86).—The germination percentage and rate of soaked hop seed was increased by alternating temperatures, best results being obtained by first submitting to the low temperature for 5 days until swollen and then transferring to the optimum temperature for germination.

"Vegetable dynamics" and plant tissue cultures, P. R. WHITE (*Plant Physiol.*, 17 (1942), No. 2, pp. 153-164, figs. 10; *abr. in Science*, 95 (1942), No. 2473, pp. 520-522).—In this address the author points out the directions in which plant physiology has moved since the days of Stephen Hales and briefly outlines some of the new fields for further work, including a few examples to indicate the proved as well as potential scope of the sphere opened up by the tissue culture technic.

Cultivation in vitro of small *Datura* embryos, J. VAN OVERBEEK, M. E. CONKLIN, and A. F. BLAKESLEE (*Amer. Jour. Bot.*, 29 (1942), No. 6, pp. 472-477, figs. 6).—Isolated heart-shaped *D. stramonium* embryos as small as 0.15-0.2 mm. and as young as 10 days after pollination were grown aseptically in vitro in an agar medium containing dextrose, mineral salts, a mixture of physiologically active substances, and nonautoclaved coconut milk. It appears that in coconut milk at least three factors are present which affect the growth of embryos—a thermolabile factor causing both growth and differentiation, a heat-stable factor causing in some cases a calluslike growth but no differentiation, and a heat-stable factor which inhibits root growth and may be related to auxin.

Limitations of auto-irrigators for controlling soil moisture under growing plants, L. A. RICHARDS and W. E. LOOMIS. (Iowa Expt. Sta.). (*Plant Physiol.*, 17 (1942), No. 2, pp. 223-235, figs. 5).—Using corn, soybean, wheat, and oats grown in various soils in 6- and 10-in. double-wall irrigator pots, it was found that with low barostat tensions good moisture control was attained while the plants were small and there was no change in the average pot weight from day to day. With larger plants, however, when the daily transpiration loss was greater than about 100 cc. per day, it was not possible to maintain the soil moisture content, even with the reservoir water supply at tensions as low as 2-4 cm. of mercury. The range of usefulness of auto-irrigators for controlling soil moisture in plant experiments thus appears to be definitely overrated in the literature. Their limitations in the range of successful operation may be ascribed primarily to the slow rate at which drying soils absorb and transmit water, particularly when the soil moisture is under appreciable tension. The hysteresis effect in the relation between the soil moisture tension and content accounts in part for the fact that it is difficult for an auto-irrigator to rewet soil from which the moisture has been depleted by roots. Also, a very slight decrease in moisture content may cause a hundredfold decrease in the moisture conductivity or permeability of soils for unsaturated flow, and local decreases are probably characteristic of the soil immediately surrounding all roots that are rapidly absorbing moisture. The design and construction of the irrigator pots used proved fairly ideal, and they appear to have a definite usefulness in soil moisture control problems not requiring the rapid movement of moisture through the soil. There are 14 references.

A non-osmotic force in the water relations of potato tubers during storage, C. J. LYON (*Plant Physiol.*, 17 (1942), No. 2, pp. 250-266).—Measuring the osmotic quantities starting with freshly dug potato tubers and continuing until they collapsed in warm storage or sprouted in cold storage, the total osmotic pressure appeared to increase soon after storage was begun but fluctuated in characteristic ways during winter and spring. During storage the turgor pres-

sure exhibited some effect of water lost by evaporation but seemed to depend more on the apparent total osmotic pressures of the cells. It often increased toward the end of the storage season, particularly in tubers with the best keeping qualities. As measured by the sucrose solution in which the volume of the tissue remained unchanged, the net osmotic pressure in cold storage usually increased during winter but became smaller in early spring. In warm storage it was higher than in cold storage only if the tubers failed to keep well. The calculated net osmotic pressures were usually significantly larger than the observed values. This discrepancy is a demonstration and an approximate measure of a nonosmotic force, which appears in early storage and varies in size with season and storage temperature. It is comparable to the "secretion pressure" reported by others and to the excess "osmotic" pressure in living tissues over that in the same dead cells, as measured by the thermocouple method for freezing point depression. In potatoes, however, the basis for it is unidentified.

The relative osmotic value of enlarging cells, W. A. BECK (*Studies Inst. Divi Thomae, Athenaeum Ohio*, 3 (1941), No. 1, pp. 1-8).—To obtain further evidence of protoplasmic activity in cell enlargement, the osmotic value (molar concentration of agent inducing incipient plasmolysis) of hypocotyl epidermal cells of sunflower (*Helianthus annuus*) seedlings was determined. The order of recorded values (0.224 M and 0.193 M) was in harmony with previous studies of many different kinds of epidermal cells, and that of cells in the upper region was 0.031 M higher than in the lower region. The difference was not deemed sufficient to account for a tenfold enlargement of the cells, thus forcing the conclusions that the protoplasm must elaborate a sufficient amount of solute to make the enlargement possible without greatly reducing the cell sap concentration, and that the cell wall must have become "fixed" to such an extent that it could not return to its earlier form during plasmolysis. The protoplasm is evidently active in the process of growth by cell enlargement, as is indicated by the production of solute.

Response of *Cyperus rotundus* L. to five moisture levels, C. H. DAVIS. (Univ. Ariz.). (*Plant Physiol.*, 17 (1942), No. 2, pp. 311-316).—Each decrease in the minimum soil moisture percentage permitted before rewetting to saturation resulted in a significant decrease in the weight of tops of *C. rotundus*, a weed known in the South as nut grass. Tuber development was decreased significantly by decreased soil moisture from a point 2 percent below the moisture equivalent. Tuber-top ratios were higher than average when the soil moisture minimum was below the wilting coefficient and lower when the minimum was above the moisture equivalent. Tuber growth was increased 150 percent and top growth 250 percent by raising the frequency of watering from a minimum of 9 to a minimum of 18 percent. The 18 percent level of watering was nearly 100 percent better than the 12 percent, even though both series were assumed to have a continuous supply of available moisture. At least in pots, growth may apparently be checked by the availability of water in soil which is always wet above the wilting percentage.

The iron-manganese ratio in relation to the respiratory CO₂ and deficiency-toxicity symptoms in soybeans, I. I. SOMERS, S. G. GILBERT, and J. W. SHIVE. (Rutgers Univ.) (*Plant Physiol.*, 17 (1942), No. 2, pp. 317-320, fig. 1).—Normal plants free from pathological symptoms were produced only when the Fe-Mn ratio in the substrate had values between 1.5 and 2.5, and the highest yields of respiratory CO₂ also occurred within this range. Furthermore, it was apparent that within reasonable limits the absolute concentrations of these elements either in the substrate or in the plant can be of no great importance so long as they are present in the proper relation to each other.

Composition of alcoholic leaf extract and the entire leaf of Irish potatoes as indices of soil fertility, C. E. BEAUCHAMP (*Plant Physiol.*, 17 (1942), No. 2, pp. 165-178).—In continuation (E. S. R., 84, p. 306), analyses of alcoholic leaf extracts showed direct relationships between the amounts of N, P, and K in the fertilizers; the percentages of these in the alcoholic leaf extracts; and the resulting yields. The same relationship held when the individual contents of these elements in the entire leaves were correlated with the fertilizer treatments on the one hand and the resulting yields on the other. However, the contrasts between the various treatments were much more pronounced in the leaf extracts than in the entire leaves. The sums of the percentages of N, P, and K in the leaf extracts and in the entire leaves were also used to study the intensity of nutrition, and in both cases there was a very marked relationship between these percentages, the fertilizer treatments, and the yields. Complete fertilizer treatments resulting in similar yields showed similar N-P-K units in both leaf extracts and entire leaves, but the units on the entire leaf basis were high in N whereas on the leaf extract basis they were high in K. On either basis, minus-K fertilizer treatments resulted in a derangement of the N-P-K units, involving a decrease in the K and an increase in the N ratios. The leaf extracts exhibited a rather constant K-P ratio irrespective of the widely different treatments compared, and its significance is discussed. Both leaf extracts and entire leaves showed the same sequence in the Ca-Mg-K relationships. When K was high Ca and Mg, individually and collectively, were low, and vice versa. "The analysis of the entire leaves of potatoes, as well as that of the alcoholic leaf extract, may be used as indices of soil fertility deficiencies, or as indicators of the nutrition of the crop. When comparing soils differing widely in fertility either one or the other may be used, but when the fertility level between soils under comparison is not very pronounced better results will be obtained by using the alcoholic leaf extracts."

Application of the liquid extraction method for the determination of total organic acids in plant sap, T. L. ISAACS and T. C. BROYER. (Univ. Calif.). (*Plant Physiol.*, 17 (1942), No. 2, pp. 296-302, fig. 1).—The liquid extraction method for determining organic acids reviewed and the apparatus designed and described were successfully applied to excised barley root sap. There are 13 references.

Recent work on the structure of plant polysaccharides, W. Z. HASSID. (Univ. Calif.). (*Chron. Bot.*, 7 (1942), No. 3, pp. 135-137).—A brief review on cellulose, starch, glycogen, fructosans, glucosans, galactans, mannans, and microbial polysaccharides, with bibliography.

Origin and transformation of carbohydrates in plants, H. A. SPOEHR (*Jour. Chem. Ed.*, 19 (1942), No. 1, pp. 20-23).—An address.

A study of the chemical composition of soybeans during maturation, A. C. WOLFE, J. B. PARK, and R. C. BURRELL. (Ohio State Univ.). (*Plant Physiol.*, 17 (1942), No. 2, pp. 289-295).—Analyses of four soybean varieties at different developmental stages indicated that seed fat and protein are probably produced largely from substances brought into the seed from other parts of the plant at time of synthesis, rather than from the carbohydrates already stored therein. Special attention is called to the desirability of expressing certain data in terms of quantity per plant or plant part rather than only in terms of percentages of the whole sample. Various modifications in the usual analytical methods were employed to render them more suited to use with this type of fresh high-fat plant material. There are 18 references.

Development of plants growing under different light conditions as affected by mineral nutrition, M. C. ČAJLACHJAN and E. K. LUKOVNIKOV (*Compt.*

Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 32 (1941), No. 2, pp. 152-155, figs. 2).—In experiments with oats and millet it was found that under photoperiods unfavorable to reproduction (short day for oats and long day for millet), their development was not affected by varying the mineral rations over a wide range. Under these conditions, no amount of mineral nutrients used could bring the plants from vegetative to reproductive growth. However, when the light conditions were favorable for the reproductive phase, the mineral supply became a very potent factor in its development. The growth of both plant species always reacted to the store of mineral matter, but it was obvious that growth was also affected by day length, irrespective of mineral supplies. Further work is needed to determine whether this two-sided influence of mineral elements is a general characteristic of plants.

Växtodling i artificiellt ljus (konstljuskultur) med särskild hänsyn till tomat [Plant culture under artificial light with special reference to the tomato plant], B. ÅBERG (*Symb. Bot. Upsal., 4 (1941), No. 5, pp. 98, pls. 7, figs. 21; Ger. abs., pp. 79-88*).—A review (10-page bibliography) and monographic study.

Developmental physiology of the grass seedling.—I, Inhibition of the mesocotyl of *Avena sativa* by continuous exposure to light of low intensities, R. L. WEINTRAUB and E. D. MCALISTER (*Smithson. Misc. Collect., 101 (1942), No. 17, pp. [1]-10, pl. 1, figs. 4*).—The relationship between the growth inhibition of the oats mesocotyl and the intensity of the radiant energy causing it was determined for a number of relatively narrow wavelength bands of the visible spectrum, at low intensities the inhibition being proportional to the logarithm of the intensity. From these data a provisional action spectrum of mesocotyl inhibition was plotted which showed a single peak at about 6,600 a. u. and an indicated secondary maximum around 6,200 a. u.

On the photoperiodic after-effect, B. S. МОШКОВ (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 31 (1941), No. 7, pp. 699-701*).—On the basis of experimental work with *Perilla*, the photoperiodic aftereffect is accounted for by those physiological changes arising in the leaves when they are under the photoperiodic conditions optimum for the plant concerned. Whatever may be the nature of these processes, they are believed to have such an effect on the life activity of the leaves that the plant becomes able to form flowers and fruits under any photoperiodic conditions. On short day length the leaves of *Perilla* have passed a certain phase of their ontogeny (probably an irreversible phase) to acquire the power of bringing to flowering the growing points controlled by them. The subsequent return to vegetative growth is due to the formation of new leaves differing in their development from those preceding. Therefore, there is believed to be no need to resort to photoperiodic accumulation to explain the aftereffect.

Rate of photosynthesis in leguminous plants supplied with free or bound nitrogen, M. M. GUKOVA and W. S. BUTKEVICH (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 31 (1941), No. 9, pp. 933-936, figs. 5*).—It is concluded from the experiments outlined that inoculation of legumes and the nature of the N nutrition determined by it have considerable influence on the physiological processes of these plants and are able to produce considerable changes in their development.

Cytoplasmic inclusions in the glandular epithelium of the scutellum of *Triticum sativum* and *Secale cereale*, J. A. O'BRIEN, JR. (*Amer. Jour. Bot., 29 (1942), No. 7, pp. 479-491, figs. 32*).—It was found that as germination begins small vacuoles form in the cells through swelling and dissolution of aleurone grains present in the resting stage, and as it progresses these vacuoles enlarge

and coalesce. In these large vacuoles there appears a vacuolar material precipitable in fixation as a lightly staining homogeneous mass. This material, possibly protein in nature, disappears at the end of germination, when the cells are completely vacuolate and devoid of vacuolar material. Plastid primordia are present in the epithelial cells during germination, and they readily develop into plastids as starch grains form within them. Two types of non-plastid-forming mitochondria also occur in these cells, the first being represented by a profusion of minute granular bodies free in the cytoplasm and the second by a type preserved by certain fixatives, not freely dispersed, each composed of a filament and enlarged terminal portion, and localized in a characteristic solitary group. This group structure is not present in the granular cytoplasm but is contained within a homogeneous region indistinguishable from the precipitated homogeneous material. Though this region may be a highly specialized portion of the cytoplasm, the evidence at hand suggested a vacuolar nature, and a relationship of the structure with secretion is deemed likely. There are 16 references.

Cell growth and division in living root meristems, R. T. BRUMFIELD (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 533-543, figs. 14).—When *Phleum pratense* seedlings were grown in a specially constructed moist chamber and groups of meristematic cells in the root tips photographed at intervals as they developed to maturity, each cell or its resultant complex was found to pass through two growth phases, elongation proceeding at a constant exponential rate in each. In the first phase the cell or complex elongated at about 5.4 percent per hour, and at its end the growth rate increased to about 41.2 percent. In the second phase the rate remained constant at 41.2 percent, falling off to zero at the end of this phase. Cell division occurred only during the first phase, which appears to be primarily concerned with the production of new protoplasm, as is the second with vacuole enlargement. The period of increasing growth rate apparently represents a transition from one growth phase to the other. The first phase occurred in a zone from the root tip to 0.14 mm. behind it, and the transition occurred in a second zone extending from 0.14 mm. to 0.31 mm. behind the root tip. The second growth phase took place in a zone extending from 0.31 mm. to 0.97 mm. behind the root tip, and in the basal end of this zone the rate fell rapidly to zero. Trichoblasts elongated less than hairless cells, the growth rate of the former increasing more gradually than that of the latter during transition from protoplasmic synthesis to vacuolization. No evidence of "rhythmic" growth was observed in root elongation, and the division process did not appear to influence the cell elongation rate.

Development of the ovule and the formation of the seed in *Plantago lanceolata*, G. O. COOPER. (*Univ. Wis.*). (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 577-581, figs. 30).—A cytological-histological study of buckhorn or English plantain.

A nomogram for finding the areas of bean leaves, W. D. BATEN. (*Mich. Expt. Sta.*). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 3, pp. 290-292, fig. 1).—'Many agricultural research workers have interested themselves in the past few years with finding the areas of leaves of various plants. The areas were found in many instances by use of a planimeter from blueprints or tracings of the leaves. This usually requires a great deal of labor and time. . . . The purpose of this article is to show how the area of a bean leaf, which is composed of three leaflets, can be found quickly by a chart which is called a nomogram.' The area of a leaf is found from the nomogram by laying a straight edge on the length axis and the width axis and then reading where the straight edge crosses the

area axis. The area is the only item that is recorded. The amount of labor is reduced to a minimum by using this device, for all areas are found in the field without computation in the laboratory and removing a leaf from the plant.

Torsions and their analysis, R. SNOW (*New Phytol.*, 41 (1942), No. 1, pp. 1-12, figs. 9).—This is a review and experimental study of torsions in plants. There are nine references.

A study of the origin and development of the cormlet of gladiolus.—I, The morphology of the corm and its appendicular organs; II, Factors influencing cormlet production; III, Anatomical studies of the cormlet, M. J. T. GEIGER (*Gladiolus* [New England Gladiolus Soc.], 1941, pp. 56-85, figs. 8; 1942, pp. 52-71, pls. 7, figs. 3).

GENETICS

New paths in genetics, J. B. S. HALDANE (*New York and London: Harper & Bros.*, [1942], pp. 206, figs. 17).—A book is presented based largely on a series of lectures given at the University of Gröningen, Holland, on genetics and its relation to other sciences. A considerable part of the book deals with human relations and statistical aspects of the subject.

Amphidiploidy, T. H. GOODSPEED and M. V. BRADLEY. (Univ. Calif.). (*Bot. Rev.*, 8 (1942), No. 5, pp. 271-316).—Investigations of the incidence and significance of amphidiploidy have recently been stimulated by the discovery of technics which induce chromosome doubling and by improvements in their application. In fact, at least one-third of the known instances of amphidiploidy have been reported since 1937 and have been artificially produced. This critical review (219 references) considers the origin and experimental induction of amphidiploidy, the origin and character of naturally occurring amphidiploids, the morphological and physiological characteristics and the cytogenetics of amphidiploids, fertility and crossability, and the evolutionary significance and distribution of amphidiploids.

Inheritance of fertility in the lateral spikelets of barley, W. H. LEONARD (Colo. Expt. Sta.). (*Genetics*, 27 (1942), No. 3, pp. 299-316, figs. 2).—The inheritance of fertility in the lateral spikelets of barley was studied in the Mortoni variety (*Hordeum intermedium*). The fertile intermedium condition found in F_1 crosses between some two- and six-row barleys is due to the genetic constitution $VvII$. Homozygous partial lateral spikelet fertility found in Mortoni appeared to be due to a fertility allele of the infertile intermedium v. nonintermedium (Ii) factor pair. The allelic series for intermedium appeared to be I , I^h , and i , with infertility dominant over fertility. The nonintermedium v. fertile intermedium (I^hi) factor pair, from combined F_1 and F_2 data, was linked with that for hoods v. awns (Kk) with 14.32 ± 0.61 percent recombination. Kk is known to be located in group IV. I^hi was found to be inherited independently of factors located in groups I, II, III, V, and VI. A method of testing barley varieties for intermedium constitution is suggested.

Inheritance of smut resistance in hybrids of Navarro oats, G. M. REED (*Amer. Jour. Bot.*, 29 (1942), No. 4, pp. 308-314).—This oats variety has proved resistant to all known races of *Ustilago avenae* and *U. levis* tested. This condition has been utilized in breeding work, and the variety is interesting for analysis of the mechanism of resistance. Hybrids of Navarro and Hull-less inoculated with *U. avenae* race 1, based on F_1 and F_2 data, indicated a two-factor relation for inheritance, and a three-factor difference was indicated when inoculated with *U. levis* race 1 and race 7. However, these hybrids inoculated with *U. avenae* race 12 differed markedly from the results just noted. There was a high percentage of inoculated F_1 plants infected, and in the F_2 generation

there was a very small number of resistant and a great excess of segregating and susceptible progenies. In hybrids of Navarro and Black Mesdag, five factors for inheritance of resistance to *U. levis* races 7 and 9 and three for *U. avenae* race 12 were indicated. In the hybrid of Navarro and Gothland, inoculated with *U. avenae* race 1, two factors were indicated. All of the parental varieties, Navarro, Hull-less, Black Mesdag, and Gothland, are resistant to the Red Rust-proof race of loose smut. An occasional F_1 progeny of Navarro \times Hull-less and Navarro \times Gothland contained infected plants. No smutted plants were found in the F_1 progenies of Navarro \times Black Mesdag. There are 18 references.

Oppositional alleles causing cross-incompatibility in *Trifolium repens*, S. S. Atwood. (U. S. D. A.). (*Genetics*, 27 (1942), No. 3, pp. 333-338).—Two series of white clover plants were compatible as females with a plant homozygous for oppositional alleles ($SiSi$). In 26 of 27 resultant F_1 progenies of from 4 to 8 plants each, 2 intrasterile, interfertile groups were found, but only one group in the other progeny. Within each series, diallel crosses were made for all F_1 groups, and each F_1 group or its heterozygous parent was crossed as a female with 6 plants, homozygous respectively for 6 other alleles. Incompatible matings indicated that the 2 alleles under test were identical. Of 26 alleles tested in the first series, 25 proved to be different, and in the second series 34 of 41 were different.

Polyploids in the genus *Cucumis*.—Preliminary account, O. SHIFFRIS. (Cornell Univ.). (*Jour. Hered.*, 33 (1942), No. 4, pp. 144-152, figs. 5).—Colchicine-induced tetraploids of the cucumber exhibited in general the expected gigantic features, with accentuated serrations of the leaf margin the most outstanding peculiarity. The dimensional change in fruit shape associated with polyploidy depends apparently on the initial genic patterns involved, the level of chromosome multiplication, and in some cases on the physiological reactions of the tetraploid plants. Sterility as a character was accentuated by chromosome doubling due to the physiological reaction of the tetraploids and the initial increase of pollen and ovule abortion. Intercrosses between diploids and tetraploids were difficult to obtain, suggesting that tetraploids represent a distinctly isolated population.

Downy mildew resistance in cucumbers, J. M. JENKINS, JR. (S. C. Expt. Sta.). (*Jour. Hered.*, 33 (1942), No. 2, pp. 35-38, figs. 2).—In 1939 more than 80 lots of cucumbers, including commercial varieties and foreign introductions, were planted at the Truck Substation near Charleston, S. C. Many of the lots succumbed to downy mildew. Among the few resistant forms, China and Puerto Rico No. 37 were outstanding. Subsequent trials indicated that Puerto Rico 37 was less affected by the mildew fungus than the China variety. Crosses made between Puerto Rico 37 and Colorado, a desirable commercial variety, and between China and Colorado yielded F_1 progenies of intermediate resistance. In the F_2 , there were plants as resistant as the resistant parent, and the F_2 was being grown in the hope of obtaining resistant types of good quality. As far as could be established, no linkage existed between the factors for resistance and those governing earliness or fruit shape.

A cytological study of some species in the tribe Paniceae, G. W. BURTON. (Ga. Coastal Plain and Ga. Expt. Stas. and U. S. D. A.). (*Amer. Jour. Bot.*, 29 (1942), No. 5, pp. 355-359, figs. 27).—The somatic chromosome numbers in 27 races of 26 species are presented, with discussions.

[Genetic studies with livestock by the Florida Station]. (Partly coop. U. S. D. A.). (*Florida Sta. Rpt. 1941*, pp. 62, 63, 67-68, 173-174, 180-182, 205-206, 206-207, fig. 1).—Brief results are presented by D. J. Smith, C. H. Willoughby, A. L. Shealy, O. W. Anderson, Jr., N. R. Mehrhof, R. B. Becker, P. T. D. Arnold, A. H.

Spurlock, R. W. Kidder, V. E. Whitehurst, Jr., W. G. Kirk, and W. F. Ward of the fleece and mutton production by Hampshire, Columbia, and crossbred sheep; the relationship between temperature, egg weight, body size, and production in Single Comb White Leghorns; variations in the fertility of Rhode Island Reds; the breeding efficiency and depreciation in Florida dairy herds; meat and milk production of Devon cattle; purebred and grade Angus cattle and Columbia sheep studies; purebred and crossbred cattle under similar environmental conditions; and inbreeding and crossing light Sussex and Rhode Island Red poultry as influencing incubation and fattening.

Experimental breeding of dairy cattle for the Tropics, E. HARRISON (*Trop. Agr. [Trinidad]*, 19 (1942), No. 4, pp. 65-69).—A tentative experimental breeding plan is developed at considerable length. Suggested original crosses are Indian-type bulls on groups of milk-recorded European-type females and the reciprocal and European-type bulls of milk-proved breeding capacity on groups of Indian-type cows which are known as milkers.

Crossbreeding in swine: Does it offer an effective method for the improvement of market hogs? W. E. CARROLL and E. ROBERTS (*Illinois Sta. Bul.* 489 (1942), pp. 121-136).—The weights and mortality of purebred and crossbred swine from various sources involving more than 50,000 head do not support the belief that hybrids may be expected in the majority of crosses between the breeds to excel in vigor, growth rate, vitality, and efficiency of production. Crossbreds approach but do not excel the better purebreds. At the same time with the crosses there may be a grading-up process of poorer stock. The high degree of homozygosity attained with corn is not possible with swine.

Some effects of breeding purebred ewe lambs, J. H. LONGWELL (*North Dakota Sta. Bul.* 316 (1942), pp. 16).—Ewes which raised lambs as yearlings were lighter in weight at 18 mo. than ewes not bred until 1 yr. older, but the difference was made up at 30 mo. in Shropshires and 36 mo. in Hampshires. The difference never entirely disappeared in Southdowns. Fleece weights were the same for ewes bred as lambs or as yearlings, but in Southdowns the fleece weights were lighter for the ewes which reared lambs as yearlings. The study was conducted over a period of 7 yr. with 95 Hampshires, 133 Shropshires, and 75 Southdown ewe lambs, approximately one-half of which were bred at about 9 mo. of age and approximately one-half at about 21 mo. of age. The production of lambs and wool is given for the ewes at each age and of each breed and for those which did and did not breed or had living or dead lambs.

[Genetic investigations with poultry and sheep by the Wyoming Station] (*Wyoming Sta. Rpt.* 1941, pp. 10-11, 11-12).—Brief results are reported by M. O. North on studies of the inheritance of resistance to coryza (roup); also on the wool and lamb characters of crossbreds produced by Corriedale and Columbia rams mated with Rambouillet ewes.

[Poultry breeding investigations by the Arizona Station] (*Arizona Sta. Rpt.* 1941, pp. 88-90).—Results are briefly reported on the development of high egg producing strains of White Leghorns, Barred Plymouth Rocks, and Rhode Island Reds; and strains of White Leghorns for low egg production and large and small egg size, with the development of strains for resistance to pullorum disease and range paralysis.

[Investigations in poultry genetics by the Massachusetts Station] (*Massachusetts Sta. Bul.* 388 (1942), pp. 95-97, 98-99).—Brief results are given by F. A. Hays, R. Sanborn, W. C. Sanctuary, and J. H. Vondell of progress on investigations relating to genetic study of Rhode Island Red and Orpington color; rapid and slow feathering in the Rhode Island Red; selective breeding for reducing mortality in Rhode Island Reds; the inheritance of intensity of egg production

and egg size in the domestic fowl; fertility cycles in ♂s; the physiological relationships between molting behavior and fecundity; breeding studies for the combination of meat and egg production in Barred Plymouth Rocks; and sexing Barred Plymouth Rocks by down and shank color and vent morphology.

Studies on the creeper fowl.—XIV, **The Japanese Bantam fowl**, W. LAN-DAUER ([Conn.] Storrs Expt. Sta.). (*Amer. Nat.*, 76 (1942), No. 764, pp. 308-317, fig. 1).—Several hundred incubated eggs from various crosses and inter se matings of creepers and Japanese Bantams and hybrids between them made it evident that the Japanese Bantam carries the creeper mutation or an allele of it. The greater survival of the homozygous embryos in the Japanese Bantam to late developmental stages than in the creepers seemed to be due to the action of an incompletely dominant modifier linked with the creeper factor. About 18-41 percent of all homozygotes lived beyond the early incubation stages. This study was conducted over several years with crosses made by artificial insemination.

Size genes of mice, W. E. CASTLE. (Univ. Calif.). (*Natl. Acad. Sci. Proc.*, 28 (1942), No. 3, pp. 69-72).—In carrying further studies of the relation of genes for pink eye, lethal yellow, and brown to size in the mouse (E. S. R., 86, p. 28), crosses were arranged to produce more than 500 litter mates in both sexes of pink-eyed brown ($aa\ bb\ p.p_1$), pink-eyed yellow ($A^y\ a\ bb\ p.p_1$), brown ($aa\ bb\ P.p_1$), and yellow ($A^y\ a\ bb\ P.p_1$). All were homozygous for b . The pink-eye gene decreased body size less than the lethal yellow raised it as regards body weight and length, but not as regards tail length.

[Physiology of reproduction in animals] (*Fed. Proc. [Fed. Amer. Soc. Expt. Biol.]*, 1 (1942), No. 1, pt. 2, pp. 33, 41, 63, 67, 119).—Abstracts are given of the following papers presented at the annual meetings of the American Physiological Society and American Society of Biological Chemists; Forty-eight-hour Response to Androsterone in the Immature Male Rat, by R. R. Greene and M. W. Burrill (p. 33); Further Studies in the Metabolism of Progesterone, by M. M. Hoffman and J. S. L. Browne (p. 41); Effects of Oestrogenic Hormone in Thyroidectomized Rats, by W. O. Nelson (p. 63); Nutrition of the Rabbit Ovum in Vitro, by G. Pincus (p. 67); and A New Method for the Preparation of Chorionic Gonadotropic Hormone, by P. A. Katzman, M. Godfrid, C. K. Cain, and E. A. Dolsy (p. 119).

The role of the endocrine glands in growth, reproduction, and lactation, C. W. TURNER. (Mo. Expt. Sta.). (*Missouri Acad. Sci. Proc.*, 7 (1942), No. 4, p. 94).—This brief abstract indicates something of the importance of the anterior pituitary in the initiation and control of secretions from various endocrines related to growth, reproduction, and lactation.

Attempts to stimulate proliferation of the germinal epithelium of the ovary, K. F. STEIN and E. ALLEN (*Anat. Rec.*, 82 (1942), No. 1, pp. 1-9).—Mitotic proliferation of the germinal epithelium was stimulated by the injection of oestrone directly into the ovarian capsule of normal and hypophysectomized mice. Support is thus given to the idea that cyclic proliferation of the ovaries through the follicular fluid may aid cellular proliferation. Histological study was made of the mitosis of the ovarian tissues 8-36 hr. after injection of the right ovary and 9 hr. after colchicine treatment. The left ovaries were frequently uninjected or injected with sesame oil as controls. Increases in mitotic activity did not occur in less than 30 hr. after injection.

The effect of growth hormone injections on the costochondral junction of the rat rib, R. D. RAY, H. M. EVANS, and H. BECKS. (Univ. Calif.). (*Anat. Rec.*, 82 (1942), No. 1, pp. 67-75, pls. 2).—Several points of difference as well as similarity were observed in the epiphyseal cartilage of the tibia and the costochondral cartilage of the rib of 18 rats up to 150 days of age. There was increased tissue metaplasia in the connective tissue of the deep layer of the perioste-

teum following injection of growth hormone. The effects were essentially opposite after hypophysectomy.

Effect of oestrin injections on the mouse ovary, W. S. BULLOUGH (*Nature* [London], 149 (1942), No. 3775, pp. 271-272).—The bursting of the graafian follicles at ovulation in normal mice releases follicular fluid rich in ♀ sex hormone which causes the postovulation peak in mitotic activity and replenishment of the ovary with a new stock of oogonia. In conducting the study, groups of 4-12 ♀ mice were injected with 1-5 doses of 250 I. U. of oestrin at 12-hr. intervals during di-oestrous. Counts of the number of mitoses varied from 25 in controls to an average of 747 after five injections of oestrin with colchicine 9.5 hr. before autopsy.

The influence of certain hormones on the carbohydrate levels of the chick, W. R. C. GOLDEN and C. N. H. LONG (*Endocrinology*, 30 (1942), No. 5, pp. 675-686).—Blood sugar levels in chicks were about 200 mg. percent with decreases of about 10 mg. percent during fasting. The carbohydrate values for liver and muscle were likewise high for the chicks as compared with mammals. The effects of insulin, anterior pituitary, and adrenaline extracts on blood sugar in chicks were also investigated.

Specificity of fowl and mammalian antigonadotropic sera, H. S. KUPPERMAN, C. H. MELLISH, and W. H. McSHAN. (Univ. Wis.). (*Soc. Expt. Biol. and Med. Proc.*, 48 (1941), No. 1, pp. 79-83).—Studies of the antigonadotropic serum produced by rabbits suggest that the gonadotropic complex of the chicken hypophysis is immunologically distinct from that observed for the mammalian gland and indicates that antigonadotropic hormones are immune bodies. The ability of antisera of different species produced by repeated injections to inhibit the gonad-stimulating effect of hormones from different animals on ovarian size of 21-day-old rats was ascertained. Chicken antigonadotropic rabbit serum, while inhibiting the gonadotropic action of chicken pituitary glands, was ineffective against gonadotropic extracts of sheep pituitary glands.

Influence of riboflavin-deficiency in eggs on embryonic development (*Gallus domesticus*), A. L. ROMANOFF and J. C. BAUERNFEIND. (Cornell Univ.). (*Anat. Rec.*, 82 (1942), No. 1, pp. 13-23, pl. 1, figs. 4).—Incubation of 1,268 fertilized but riboflavin-deficient eggs (*E. S. R.*, 82, p. 379) showed three critical periods in mortality at about 4, 14, and 20 days. The average embryonic mortality of these eggs was 87.5 percent. Prior to death there was a reduction in size of the riboflavin-deficient embryos, and shortened legs and prognathism were characteristic of the chicks from eggs deficient in riboflavin.

Relative growth of the shank (tarsometatarsus) in domestic ducks, H. CONNALLY and R. G. JAAP. (Okla. Expt. Sta.). (*Okla. Acad. Sci. Proc.*, 21 (1941), pp. 15-16).—The tarsometatarsus of the common duck was found to reach its maximum length at a very early age, but it increased in length at a slower rate than the body as a whole which was very rapid after hatching. The shank appeared to exhibit negative allometry during growth. From these results larger ducks would be expected to have proportionally shorter shanks than smaller ducks.

Effects of castration on feather weight in domestic fowl, K. B. TURNER. (Okla. Expt. Sta.). (*Okla. Acad. Sci. Proc.*, 21 (1941), pp. 93-94).—Although both capons and cockerels of the Barred Plymouth Rock breed continued to increase in body weight from 24 to 40 weeks of age, the differences were nonsignificant. By 24 weeks of age the feather weights of the capons were significantly greater than the cockerels, and at 40 weeks of age the minimum feather weight represented 7.6 percent of the body weight for capons and 6.3 percent for cockerels. The data were based on approximately 10 birds killed at about 5-week intervals.

FIELD CROPS

[Field crops research in Arizona]. (Partly coop. U. S. D. A.). (*Arizona Sta. Rpt. 1941*, pp. 29-36, 46-48, 74-79, 81-82).—Agronomic experiments (E. S. R., 85, p. 608) reported on from the station and substations included variety tests with cotton, grain sorghum, wheat, clover, castor-beans, soybeans, and green manure crops; breeding work with wheat (for smut and rust resistance), alfalfa, and cotton; experiments concerned with irrigation needs of cotton and depths of planting delinted seed; fertilizer tests with alfalfa and seed flax; effects of fertilizers, manure, and green manure on crops in rotations; seed production studies with alfalfa and sugar beets; cultural and interplanting (with hegarl) tests with soybeans and trials of soybeans and Sudan grass mixtures; date-of-seeding test with seed flax and green manure crops; economic value of some range plants under cultivation, including cockroach plant (*Haplophyton cnicoidum*), yucca (*Yucca elata*), canaigre (*Rumex hymenosepalus*), and jojoba (*Simmondsia californica*); relation of climatic and grazing conditions to desert grassland range; food reserves of burroweed in relation to control practices; and control of bindweed, white horsenettle, and nutgrass by different methods.

[Field crops research in Connecticut] (*Connecticut [New Haven] Sta. Bul. 452 (1942)*, pp. 16, 18-19, 25-26).—Reports are made (E. S. R., 86, p. 32) by D. F. Jones, P. J. Anderson, et al., from tobacco experiments at Windsor (p. 796), including development of improved types of shade tobacco, fertilizer placement, and tests of relative efficiency of N carriers; and breeding and genetic investigations with corn concerned with transmission of combining ability of inbred strains of corn, changes in color and chemical composition of the aleurone and endosperm in highly aberrant stocks, sterility factors affecting pollen and ovule abortion, growth changes as associated with chromosome breaks and relocations at particular places, reciprocal translocations among chromosomes of a uniform long inbred strain of dent corn induced by X-ray treatment of the pollen, and naturally occurring changes in the rate of growth or in form among long inbred strains of corn.

[Field crops investigations in Florida]. (Partly coop. U. S. D. A.). (*Florida Sta. Rpt. 1941*, pp. 39-45, 45-56, 118-119, 128, 131, 132, 166, 167-176, 178, 180, 182-183, 198-200, 205, 206, figs. 5).—Progress reports are made again (E. S. R., 85, p. 608) from experimentation with field crops and related agronomic research at the station and substations by W. A. Carver, F. H. Hull, W. E. Stokes, J. P. Camp, G. E. Ritchey, W. A. Leukel, H. Mowry, R. E. Blaser, F. T. Boyd, F. Clark, M. N. Walker, M. N. Gist, C. S. Rude, E. N. McCubbin, A. H. Eddins, F. B. Smith, G. C. Wilson, G. M. Volk, H. W. Winsor, T. Bregger, F. D. Stevens, J. R. Neller, F. S. Andrews, W. T. Forsee, Jr., R. R. Kincaid, J. D. Warner, E. M. Andersen, W. M. Fifield, and W. F. Ward, including breeding work with corn, sweet corn, oats, sugarcane, and peanuts; variety tests with corn, oats, cotton, sugarcane for sugar and sirup, potatoes, peanuts, clover, lespedeza, grain sorghums, sorgo, and miscellaneous forage and pasture grasses and legumes and cover crops; strain tests with potatoes, pearl millet, sorghum, Napier grass, pigeonpeas, and *Indigofera hirsuta*; production tests with ramie and Alyceclover; fertilizer tests with sugarcane, potatoes, ramie, clover, lespedeza, Alyceclover, and Napier grass; study of development and deterioration of roots in relation to growth of pasture plants (Sudan and Bahia grasses) under different fertilizer and cutting treatments; fertilizer-cover crop experiments, nutritional sprays, and treatment of Dakota seed of the Bliss Triumph potato with tetrachloroethylene to break dormancy, all with potatoes; sugar-

cane studies, including physiology of blooming, the best depth of water table for cane and sugar production, and effects of the breeding of sugarcane on its utilization of P and K; cultural tests with corn, potatoes, grain sorghum, and peanuts; seed potato handling and storage; methods of inoculating legumes, particularly clovers and peanuts, in Florida soils; soil factors affecting the availability of the major elements in fertility studies with bright tobacco; effects of fertilizers, varieties, and cultural factors in production of flue-cured tobacco; tobacco plant bed fertilization; study of yield and quality of sea-island cottons, especially as to variety and effect of place of growth of seed; crop rotation studies with corn, cotton, crotalaria, and beggarweed, corn and runner peanuts rotating with crotalaria and with native cover crops, and corn in a 2-yr. rotation with crotalarials and weeds or natural land cover; and the effect of burning off weeds before spring plowing upon yield of succeeding crops.

Pasture research, in addition to that noted above, dealt with effect of fertilizer on yield, grazing value, and chemical and botanical composition of pastures; eradication of weeds in tame pastures; forage nursery and plant adaptation studies and forage and pasture grass improvement; growth behavior and relative composition of range grasses as affected by burning and effects of burning on maintenance of natural grass stands and upon establishment of improved grasses; grazing value of certain grasses for pasture on cut-over, dry Norfolk sand areas; studies of pasture legumes, of Napier grass for pasture purposes, and of water pasture; and methods of establishing permanent pastures under various conditions.

Farm and garden crops (*Kans. State Bd. Agr. Bten. Rpt.*, 32 (1939-40), pp. 205-230, figs. 7).—Articles in this paging include Reestablishing Native Grass in Kansas, by L. C. Aicher (pp. 205-210) (Kans. Expt. Sta.); Improvement of Buffalo Grass in Kansas, by L. E. Wenger (pp. 211-224) (U. S. D. A. and Kans. Sta.); Madrid Sweet Clover, a New Crop, by J. W. Zahnley (pp. 224-227) (Kans. State Col.); and Spring Frost Escape Dates for Kansas, by R. L. Fox (pp. 227-230).

[Field crops research in Kentucky] (*Kentucky Sta. Rpt.* 1941, pp. 9-12, 17-18, 19-21, 47-48).—Field crops experiments at the station and substations (E. S. R., 85, p. 751), reported on briefly, included tobacco investigations embracing effect of manure on yield and quality of burley tobacco, fertilizer tests on soil experiment fields, fertility v. moisture in the growth of burley tobacco, row spacing of burley tobacco, vitamin B₁ in setting plants, priming the lower leaves of burley tobacco, and tobacco-curing experiments with burley and dark tobacco; tests of Kentucky bluegrass and other grasses in mixtures; alfalfa-grass combinations; nurse crops for grass or lespedeza; red clover-alfalfa mixtures; bluegrass and legumes v. bluegrass alone; effect of soil N level on bluegrass seed development; effect of B on the growth of soybean plants; breeding work with corn and hybrids and red clover (coop. U. S. D. A.); variety tests with corn and hybrids, red clover, soybeans, and castor-beans; and tests of dichloroethyl ether for control of dandelion and other weeds.

[Field crops work in Massachusetts] (*Massachusetts Sta. Bul.* 388 (1942), pp. 7-8, 9, 11, 11-12, 13, 13-15, 38-40).—Agronomic and related investigations again reported (E. S. R., 85, p. 752) by W. S. Eisenmenger, K. J. Kucinski, G. Wenzel, R. W. Donaldson, W. G. Colby, H. M. Yegian, and C. E. Cross included studies on the effects of preceding crop plants and application of commercial organic materials on yield and quality of tobacco; the influence of preceding plants and corn stover of high lignin content on brown root rot of tobacco; the absorption and excretion of K and Ca by the roots of barley in

different solution media and changes in pH; planting tests with sunflowers for seed; comparisons and production of hybrid corn; influence of soil fertility on productiveness of pasture species; comparison of a system of hay-pasture management with pasturing alone and tests of summer seeding of pasture mixtures v. spring seeding; variety tests with potatoes and oats; borax studies, including effects of 25- and 50-lb. per acre applications on field stands of alfalfa, especially in regard to deficiency symptoms, as yellows, and effects of 20-lb. applications per ton of fertilizer on potatoes; and control of weeds and shrubs of cranberry bogs by chemicals and a study of effects on bog weeds of flooding to kill root grubs.

[**Field crops research in Wyoming**] (*Wyoming Sta. Rpt. 1941*, pp. 4-5, 6-7, 29-31, 32-33, 34-37).—Experimentation (E. S. R., 85, p. 43) with field crops, range, and pastures at the station and substations, reported on briefly, comprised variety tests with winter and spring wheat, oats, barley, rye, grain sorghum, sorgo, corn (and hybrids), potatoes, peas, alfalfa for yield and wilt resistance, soybeans, and miscellaneous forage grasses and pasture mixtures; breeding and certification work with potatoes; cultural (including planting) experiments with corn, wheat, barley, potatoes, sugar beets, crested wheatgrass, brome grass, Sudan grass, and alfalfa; effect of a shelterbelt on yield of crested wheatgrass; fertilizer trials with wheat, potatoes, Sudan grass, and sugar beets; ordinary, grazed, manured, and fertilized crop rotations; methods of preparing seedbeds for different crops; pasture studies; tests of range grasses; and control of quackgrass by cultivation.

Rotation and fertilizer experiments in southwest Virginia, W. R. PERKINS, A. L. GRIZZARD, and T. B. HUTCHESON (*Virginia Sta. Bul. 339 (1942)*, pp. 15, fig. 1).—Experiments to determine the most desirable length of rotations and effects of different fertilizer treatments on crop yields in a 3-yr. rotation were conducted, 1930-41, on Dunmore silt loam at Glade Spring.

The 3-yr. rotations, corn, wheat or barley, red clover, 1 yr. each, returned the highest combined yields of all crops, gave more economical use of atmospheric N gathered by the clover than the longer rotations, and are particularly recommended for dairy farms and other farms where young animals and sheep are kept and in all cases where a limited acreage of suitable plowland is available. The 4- and 5-yr. rotations, if they do not necessitate plowing of steep land, may be useful on farms raising older beef cattle and horses. Where land is adapted to alfalfa production and much hay is needed the rotation consisting of corn 2 yr., followed by alfalfa and timothy 4 yr., may be used. On steep land a cover crop of crimson clover and ryegrass or rye alone may be sown between the two corn crops to reduce soil erosion and to provide some late-fall and early-spring grazing.

In the 3-yr. rotation corn, wheat, and clover hay, liming resulted in marked increases in yield and quality of corn and clover hay and also increased the efficiency of all fertilizers used. The largest percentage increases in the yields of corn, wheat, and clover and quality of corn followed the use of P. Additional increases in yields were obtained from NP or NPK. Fertilizer recommendations for the crops in rotations are based on the results.

Pastures to hold and enrich the soil, A. T. SEMPLE and M. A. HEIN (*U. S. Dept. Agr., Farmers' Bul. 1900 (1942)*, pp. 11+29, figs. 23).—Ways to use pasture or meadow best on seven classes of land that have differences in soils, slopes, susceptibility to erosion, and need for protective measures are outlined. The value of using pasture in livestock production is pointed out, and the importance of pastures in providing essential foods is emphasized. Examples of conservation planning for farms involving the use of pastures taken from the Corn and Cotton Belts are included.

The revegetation of abandoned cropland in the Cedar Creek area, Boone and Callaway Counties, Missouri, W. B. DREW. (Coop. U. S. D. A.). (*Missouri Sta. Res. Bul. 344* (1942), pp. 52, figs. 18).—Studies, 1940–41, in central Missouri revealed that the initial vegetation supported by abandoned cropland in the area is composed largely of weeds, chiefly annuals that coexisted with the last crop grown. On cornfields fall panic grass, large crabgrass, and common ragweed appeared to be the chief weeds. After small grains the important weeds included many of those of cornfields and a number characteristic to the small grains, including bracted plantain, lance-leaved ragweed, and trailing wild bean. After an initial period of 2–3 yr., abandoned cropland is gradually invaded by perennials, among which gray goldenrod, white heath aster, and sometimes broomsedge shortly become dominant, persisting in old fields for at least 30 yr. Native forage grasses, as bluestems, are comparatively unimportant in the natural revegetation process of most of the region, but may rarely invade pastures on Putnam soils.

Sassafras (the more abundant) and persimmon, both present as sprouts at the time of abandonment of many fields, are dominant among woody plants until 20–30 yr. or more after the last cultivated crop. Smooth and winged sumacs are the most abundant among shrubs in abandoned, ungrazed cropland in the area. Typical forest shrubs, as aromatic sumac, do not become established naturally in former cropland until an arborescent canopy has developed in the late old-field stages of plant succession. Oaks, hickories, elms, ash, maple, and other forest species appear gradually to invade old fields as seedlings become established. Post and shingle oaks and shagbark hickories are commonly present as sprouts and seedlings in early stages of old-field development, whereas white oaks mostly appear as seedlings late in old-field development. In the oldest fields studied, 30–35 yr. after abandonment, sassafras and persimmon are still prominent, and typical forest species, although then dominant, are not at all comparable in frequency and density to those of second-growth woodlands in the vicinity, thus suggesting a long interval prerequisite for reestablishment of such forest conditions.

Presence of a community of a lespedeza (*Lespedeza virginica*) and a panic grass on dry western or southern sites where 75–100 percent of the topsoil had been removed was the outstanding relationship observed between a plant community and site factors, including degree of erosion. Different species of algae, chiefly of the Myxophyceae, are common in the soil of abandoned cropland, but these studies indicated that such cryptogams are not important as pioneering plants on eroded soil.

Range forage production in relation to time and frequency of harvesting, R. LANG and O. K. BARNES. (Coop. U. S. D. A.). (*Wyoming Sta. Bul. 253* (1942), pp. 32, figs. 4).—Clipping experiments at the Archer Substation, 1940–41, showed that short grasses, *Bouteloua gracilis* and *Buchloe dactyloides*, yield more when harvested frequently at ground or crown level than when protected during the growing season and harvested after growth ceases. This held true even on areas harvested in this way for 2 yr. without apparent decrease in density of perennial grasses. Midgrasses yielded significantly higher under protection and harvesting at the end of the growing season than under frequent clipping. Annual forbs, like the midgrasses, yielded lower under frequent clipping, whereas perennial forbs reacted like the short grasses in giving a higher yield under frequent clipping. Indications were that on a short-grass range a system of grazing which would use some forage during June and July and the remainder at the end of the growing season would give a greater amount of more palatable forage than a system which deferred grazing until the end of the growing season. The smaller amount of forage received by frequent grazing of a mid-

grass range possibly would offset in quality the extra quantity received by end-of-season grazing.

Estimating the value of range forage for grazing use by means of an animal-unit-month factor table, M. A. SHIPLEY, C. E. FLEMING, and B. S. MARTINEAU (*Nevada Sta. Bul. 160 (1942), pp. 26, figs. 2*).—The system of range forage appraisal developed takes into account the density or degree of ground covered and the quantity of air-dry forage produced by range plants under proper use. Determination of carrying capacity under proper use is facilitated by an animal-unit-month factor table and a grazing capacity gage by which the percentages of an area occupied by various plants may be converted readily into animal-unit-months of feed produced.

Hay mixtures in the Upper Peninsula of Michigan, B. R. CHURCHILL and E. VANDERMEULEN (*Michigan Sta. Quart. Bul., 24 (1942), No. 4, pp. 322-325*).—Alfalfa, alsike, and red clover sown alone and in mixtures with timothy or smooth brome grass at Chatham were cut for hay, 1938-41. In general, mixtures including either timothy or smooth brome with legumes produced more forage than the pure cultures. Alfalfa was the most effective legume in producing high yields, and all mixtures with alfalfa produced more hay per acre than did alfalfa alone. Timothy and smooth brome grass were of equal merit as to yield when combined with alfalfa, alsike, or their mixtures. Individual crops apparently could be added to the mixtures at different rates without appreciably changing the yields.

Corn and oats, H. O. WEST (*Mississippi Sta. Bul. 368 (1942), pp. 127, figs. 16*).—Information compiled largely from reports of experiments by State experiment stations covers a comparison of corn and oats as to production on Mississippi farms, labor requirements, feed for livestock, and harvesting machinery; varieties, seedbed preparation, planting dates and rates, and fertilizers and other fertility practices for both crops; corn cultivation; harvesting oats; and control of oats smut.

Combine vs. binder-separator harvesting for quality barley, J. W. THAYER, JR. (*Michigan Sta. Quart. Bul., 24 (1942), No. 4, pp. 294-298*).—Analyses of barley samples collected from combines and separators operating in the Thumb district in 1940 showed that with the binder-separator (35 samples), combine-standing grain (45), and combine-windrow grain (30), respectively, 80, 66, and 53 percent of the samples were classed as bright or slightly stained; had 11.3, 11.3, and 9.3 percent of moisture; 46.8, 47.8, and 45.9 lb. per bushel test weight; and 71.4, 37.8, and 56.7 percent of the samples had from 0 to 5 percent of skinned and broken kernels. There appeared to be a better chance of obtaining high-quality barley by harvesting the crop with a binder and threshing with a separator than by use of a combine. Adjusting the machine, waiting until grain is dry before starting harvest, and frequent checking of the condition of separated grain with necessary adjustments are suggested.

Ladino white clover for the Northeastern States, E. A. HOLLOWELL (*U. S. Dept. Agr., Farmers' Bul. 1910 (1942), pp. [2]+10, figs. 6*).—Practical information is given on the characteristics and adaptation of Ladino clover (*Trifolium repens*); fertilizers, seedbeds, and planting; its use for pasture, hay and silage, and cover crop; diseases and insects; and seed production.

Cotton spacing in the Yazoo-Mississippi Delta, H. A. YORK (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 7, p. 2*).—Results of cotton spacing tests at Stoneville, 1925-39, are reported briefly.

Sugar-beet culture in the intermountain area with curly top resistant varieties, B. TOLMAN and A. MURPHY (*U. S. Dept. Agr., Farmers' Bul. 1903 (1942), pp. 11+52, figs. 29*).—Cultural and field methods and harvesting prac-

tices approved for growing sugar beets in Colorado, Utah, Idaho, Oregon, and Washington are described, with advice on control of curly top and other diseases, nematodes, and insects. Major factors in sugar beet production in the region are use of curly top-resistant varieties, cultural practices, seed sources, climate, soil requirements, and irrigation supply. The information given supersedes that in *Farmers' Bulletin* 1645 (E. S. R., 64, p. 834).

Studies of the production of sweet potatoes for starch or feed purposes, W. D. KIMBROUGH (*Louisiana Sta. Bul.* 348 (1942), pp. 13).—Date of planting and digging experiments and spacing tests largely with Triumph sweetpotatoes on Lintonia silt loam, 1938–41, supplemented by determinations for moisture, reducing and total sugars, and starch, showed that highest yields could be had by setting plants in the field as soon as possible after danger from cold injury is passed, i. e., from April 15 to May 15 in south Louisiana. Spacing of from 2 to 3 ft. in the rows, farther apart than for table stock, is advised. Yield data indicated that the longer growing season resulted in the higher yields. Since a growing period of 4 mo. was shown to be needed for fair yields, mills cannot begin operations before August or probably not until September. For the growers, October and November are the best months for harvest so far as yield is concerned. As earlier diggings may be necessary for the mill, proportionate allotments should be made to all growers supplying the mill, and these should come from early plantings. Diggings more than a month after a killing frost may give inferior roots. Tests to date show that the seedling L 4-5 is very promising and likely to replace Triumph as a starch and feed variety.

Tobacco Substation at Windsor, report for 1941, P. J. ANDERSON and T. R. SWANBACK (*Connecticut [New Haven] Sta. Bul.* 457 (1942), pp. 227–266, figs. 4).—Experimentation with cigar-leaf tobacco (E. S. R., 85, p. 759) reported on dealt with fertilizers, amendments, irrigation, and plant bed covering. Accounts of frost damage, the incidence and control of diseases, and insect investigations are noted on pages 813, 822 of this issue.

The relative crop-producing capacity of urea and cottonseed meal (pp. 229–234).—Results of comparisons, 1937, 1939–41, indicated that urea N is at least 14 percent more efficient than cottonseed meal N in crop-producing capacity. In the 1941 crop urea did not increase the percentage of dark grades nor decrease the percentage of the better light grades. For the same quantity of fertilizer N the grade index was uniformly higher for tobacco receiving urea.

The effect of some sources of phosphorus on cigar leaf tobacco, T. R. Swanback, M. F. Morgan, and P. J. Anderson (pp. 234–239).—Calcium metaphosphate and triple superphosphate resulted in yields about 7 percent higher than no P, precipitated bone about 5 percent higher, and steamed bone equaled it, whereas yields with potassium metaphosphate and potassium calcium metaphosphate averaged 15 percent lower than no P. Only calcium metaphosphate of the materials tested produced tobacco decidedly superior in grade to that of the controls, and there was about 12 percent less "darks." Considering relative quality, the ranking of P sources tested would be calcium metaphosphate, precipitated bone, steamed bone, potassium metaphosphate, potassium calcium metaphosphate, and triple superphosphate. The phosphoric acid content of cured (air dry) tobacco ranged from 0.45 percent with calcium metaphosphate to 0.52 with triple superphosphate.

The effect of source on magnesium absorption by tobacco, T. R. Swanback (pp. 239–242).—Yields and grades of tobacco and leaf contents of Mg and Ca suggested that either magnesian limestone or hydrated lime may be used as a Mg source with about equal advantage, although the limestone might be safer in fertilizer mixtures. There may be a choice between these two materials when relatively small quantities of lime are needed, but if larger quantities (from

0.75 to 1 ton) are to be applied, calcic limes should be used to prevent a surplus of Mg in the leaf. The Mg requirement in the latter case is most readily met by inclusion of magnesian lime or $MgSO_4$ in the fertilizer.

Residual effect on stable manure (pp. 242-243).—The second crop after 10 yr. of heavy manuring did not show improvement in grading compared with no previous manure. An acre yield increase of 136 lb. (7 percent) was smaller than was shown the first year but still showed a residual effect 2 yr. after manuring.

Further experiments on starter solutions (pp. 243-244).—Relatively weak starter solutions were found beneficial, although sodium nitrate alone probably would benefit growth and quality better than mixtures of several nutrients. A suggestion is that not more than 3 gal. of a stock solution, as sodium nitrate 50 lb. to 50 gal. of water, should be used for a setter barrel.

Use of carbon black to activate growth early in the season (pp. 244-246).—Carbon black applied in 1941 at the rate of 850 lb. per acre in 4-in. bands on either side of the row seemed to accelerate nitrification processes greatly. Tobacco from control rows was judged of very good quality, with only a few starved (yellowish) leaves, while that from carbon black-treated rows was only fair, being somewhat coarse and including starved leaves. The somewhat higher yield from the carbon black treatment did not cover additional costs for material and labor.

Further information on irrigation of tobacco (pp. 246-247).—On a sandy soil irrigation alone may be more harmful than beneficial, for it resulted in a reduction of 26 percent in the crop value (crop index). When sodium nitrate was added to the water both yield and grade index were materially increased, with a gain of 15 percent in crop value. Results of previous experiments were confirmed.

Lumarith as a substitute for glass in seed bed sash (pp. 247-248).—Plants in beds covered by lumarith did not grow faster than those under glass nor show any difference in vigor or leaf color. Rows of plants from the glass-covered beds yielded higher, but the grading was a little better on the lumarith plants.

Physiological studies with the tobacco plant, G. M. WARD (*Canada Dept. Agr. Pub. 729* (1942), pp. 100, pls. 2, figs. 2).—Part 1 of this monograph considers mineral investigations, including some effects of K and of P on cigar tobacco, and mineral absorption studies with tobacco, including several trace elements. Part 2 covers carbohydrate investigations, including those in flue-cured and cigar tobacco. An appendix presents tables of analytical results from the mineral absorption experiments, and summaries and bibliographies conclude the various sections.

Distribution of the varieties and classes of wheat in the United States in 1939, J. A. CLARK and K. S. QUISENBERRY (*U. S. Dept. Agr. Cir. 634* (1942), pp. 75, figs. 67).—The distribution and acreages of classes and varieties of wheat are shown from surveys for the crop year 1939, based largely on seeded-acreage estimates, and are compared with the distribution in 1919, 1924, 1929, and 1934 (*E. S. R.*, 77, p. 478). The distribution of the more important wheats is shown on varietal maps, and estimated acreages and percentages of the total wheat acreage occupied by each variety or class in these years are tabulated by States and for the United States. Total acreage in the United States in 1939 in round numbers was 64 million acres, higher than the 1929-38 average of slightly less than 57 million acres, and compared with 61 million acres in 1934, 62 million in 1929, and 51 million in 1924. Decided acreage increases were in Oklahoma, Kansas, Nebraska, Montana, Missouri, Wyoming, California, Colorado, Iowa, and Idaho, and the largest decreases in acreage were in North Dakota, South Dakota, Indiana, Illinois, Michigan, Virginia, and South Carolina.

Thatcher, Tenmarq, and Blackhull made the greatest increases in percentage of acreage during the 1934-39 period, and Marquis, Turkey, and Ceres made the greatest decreases. Varieties grown on more than 1 million acres listed in order of importance included Turkey, Blackhull, Thatcher, Ceres, Tenmarq, Marquis, Kanred, Fultz, Trumbull, Fulcaster, and Kawvale.

Weak seed rightly blamed for some failures in stand. M. T. MUNN (*Farm Res. [New York State Sta.], 8 (1942), No. 3, pp. 7, 11, figs. 2*).—Germination tests showed plainly that many commercial stocks of certain kinds of seed, as well as those in farmers' seed bins, were not strong in vitality, especially those seeds the supply of which was very short and where every available source of supply was being used. Alaska peas, onion seed, corn, oats, and soybeans are examples.

Seed quality vital in all-out production; only high quality seed should be saved. B. THORNTON (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 3, pp. 22-23*).—A popular discussion.

Selective sprays for weed control in crops. L. E. HARRIS and G. R. HYSLOP (*Oregon Sta. Bul. 403 (1942), pp. 31, figs. 12*).—Almost complete control of many annual and certain perennial weeds found growing with grain, grass, peas, and flax crops was found possible by use of a new selective spray method developed in experiments, 1938-41. Combinations of sodium dinitro-o-cresylate (Sinox) with ammonium sulfate used as a selective spray were effective mainly in killing common broad-leaved weeds found growing with small grains, grasses, flax for fiber or seed, peas, and certain other specialty crops. On the other hand, the broad-leaved potato and vetch plants are effectively killed by the spray. Both of these chemicals contain nitrogen, which often has a pronounced fertilizing effect on the crop. Removal of weed competition also results in more moisture and plant food to support crop growth, and the yield and quality of crop may be increased materially. Grain yields were increased from 3 to 45 bu., common ryegrass to as much as 300 lb., and fiber flax 1 ton or more per acre. Equipment capable of complete and uniform coverage of weeds with spray under favorable weather is necessary for good results. Such spraying of weedy fields is estimated to be economically feasible.

Weeds in Kansas. F. C. GATES. (*Kans. State Col. (Kans. State Bd. Agr. Rpt., 60 (1941), No. 243, pp. 360, [pls. 4], figs. 397*).—This weed manual comprises individual descriptions, control methods, and illustrations for about 400 weeds grouped as I (20) noxious, pernicious weeds; II (43) weeds most commonly found in cultivated land, (18) in native prairies used as pastures or meadows, (11) along roadsides, railroads, and waste places, and (8) in lawns; and III about 300 plants not real weeds or not serious at present. A classified table of Kansas weeds, a bibliography, glossary, and index are included. General discussion is accorded the weed problem and eradication and control measures, especially for bindweed. Space is also devoted to insects and plant diseases harbored by common weeds, poisonous plants, hay fever plants, weeds infesting sports fields and orchards, and harm to the dairy industry and poultry caused by weeds.

HORTICULTURE

[Horticultural studies by the Arizona Station] (*Arizona Sta. Rpt. 1941, pp. 56-69, fig. 1*).—Included are reports on the following investigations: Lettuce fertilization, cantaloup and lettuce breeding and selection, vegetable variety trials, vegetable adaptation tests on the Yuma Mesa, vegetable and herb seed production, citrus fertilization, factors affecting quality and yield of grapefruit and of navel oranges, nitrogen uptake by grapefruit trees, climatic require-

ments of the pecan in the Yuma Valley, methods of top working pecan trees, relation of sunshine to winter dormancy in the pecan, treatments to overcome delayed foliation in the pecan, factors involved in the filling of pecan nuts, dates for harvesting pecans, date maturation and storage, date variety tests in the Tempe garden, and fruit and rootstock tests.

[**Horticultural studies by the Connecticut State Station**] (*Connecticut [New Haven] Sta. Bul.* 452 (1942), pp. 16-18).—Progress reports by D. F. Jones et al. are presented on the breeding of hybrid sweet corn, the effect of environmental factors on the color and sugar content of garden beets, and the breeding of hybrid summer squash, tomatoes, peppers, and strawberries.

[**Horticultural studies by the Florida Station**]. (Partly coop. U. S. D. A.). (*Florida Sta. Rpt.* 1941, pp. 79-84, 86-93, 100-101, 119-121, 133, 138-139, 143-149, 159-160, 172-173, 174-175, 192-195, 197-198, 199, 200, *figs.* 4).—Included are progress reports on the following studies by G. H. Blackmon, R. D. Dickey, R. J. Wilmot, F. S. Jamison, V. F. Nettles, L. B. Nash, A. L. Stahl, L. H. Rogers, W. Reuther, F. S. Lagasse, H. M. Sell, R. W. Ruprecht, J. R. Beckenbach, D. G. A. Kelbert, E. N. McCubbin, and E. Borda: Cooperative fertilizer tests in pecan groves; varieties of pecans and other nut-bearing species; propagation, planting, and fertilization tests with tung trees; chlorosis in ornamental figs; a "blight" or "rust" of gladiolus; cover crop tests in pecan orchards; phenological tests with truck crops; relation of nitrogen absorption and storage to growth and production in the pecan; little leaf of peaches; rootstocks for satsumas; the relation of soil reaction to growth and yield of vegetable crops; selection and development of varieties and strains of vegetables for commercial production in Florida; the effects of green manure crops on growth, yield, and quality of certain vegetables; fumigation of horticultural crops and nursery stocks with methyl bromide and HCN; effects of mineral deficiencies on the adaptability of certain vegetable varieties; the effects of Ba and Sr on growth, reproduction, and composition of tomatoes and soybeans; the cultural requirements of the mu-oil tree (*Aleurites montana*); the work of the U. S. Field Laboratory for tung investigations; soil, fertilizer, and variety studies with celery; lettuce variety and fertilizer tests; the relation of temperature and time of planting to several strains of crisp-head lettuce; cultural studies with crisp-head lettuce; the breeding and selection of tomatoes under local conditions; the suitability of various summer cover crops for sandy soils; cabbage production and variety studies; varietal and cultural trials with beets, carrots, spinach, peas, and lettuce; and nitrogenous fertilizers for citrus.

Studies are reported from the Citrus Substation by J. H. Jefferies, A. F. Camp, M. Peech, V. C. Jamison, F. F. Cowart, B. R. Fudge, W. L. Thompson, R. K. Voorhees, and W. W. Lawless on citrus progeny and bud selection, variety testing, and breeding; production and physiological studies with citrus; fruit quality studies, particularly as affected by nutritional treatments; and fertilizer requirements of citrus.

Studies from the Everglades Substation by G. R. Townsend, F. S. Andrews, and J. R. Neller include tree fruit trials and other introductory plantings, the puffing of tomatoes, water tables for truck crops, and variety tests with truck crops grown at different fertility levels.

From the Subtropical Substation studies are reported by S. J. Lynch, G. D. Ruehle, W. M. Field, and E. M. Andersen on citrus culture, avocado culture, the growing of various forest species, the testing of papayas, mangoes, and other minor fruits and ornamentals, and varieties of lima beans and lettuce.

[**Horticultural studies by the Kentucky Station**] (*Kentucky Sta. Rpt.* 1941, pp. 29-30, 30-31, 46-47).—Included are reports of soil management studies in

apple and peach orchards, the testing of early-maturing varieties of apples, mulching experiments with red raspberries, spraying of lima beans with naphthaleneacetic acid to reduce blossom drop, effect of potassium iodide on ascorbic acid content of tomato plants, and tests of fruit varieties by the Western Substation.

[*Horticultural studies by the Massachusetts Station*] (*Massachusetts Sta. Bul.* 388 (1942), pp. 8-9, 13, 40-43, 50, 56, 67-69, 75-78, 78-94, fig. 1).—Brief progress reports are presented on the following studies: The intake by plants of elements applied to the soil in pairs compared with the intake of the same elements applied singly and magnesium requirements of plants, both by W. S. Eisenmenger and K. J. Kucinski; onion breeding, by H. M. Yeglian; development of strains of cranberry resistant to false blossom and the oxygen content of winter flooding water in relation to injury to cranberry vines, both by H. F. Bergman (coop. U. S. D. A.); frost protection by a wind machine on a cranberry bog, by C. I. Gunness; breeding snapdragons for varietal improvement and disease resistance, cultural requirements of freesias, soilless culture of flowers, the liming of carnation soils, disease resistance and heredity in the carnation, and coffee chaff as a soil amendment, all by H. E. White; the testing of packet flower seeds, by C. L. Thayer; effect of plant growth-promoting substances on the rooting of Canada hemlock cuttings, propagation of mountain laurel, lilac, and juniper, factors affecting the growth of nursery stock, variety tests of herbaceous plant materials, hardiness of clematis varieties, factors influencing the hardiness of evergreens, and propagation of Mugho Swiss pine, all by H. S. Tiffany; variety tests of vegetables, tomato breeding, the mulching of tomatoes and peppers, sources of organic matter for greenhouse tomatoes, treatment of bean seed, and the testing of edible soybeans, all by W. H. Lachman and G. B. Snyder; shape index of tomatoes, sweet corn breeding, and testing of hybrid sweet corns, all by Lachman; treatment of cucumber seed, by O. C. Boyd and Lachman; improvement of asparagus by selection and vegetable breeding for improvement of quality, both by R. E. Young; influence of clonal rootstocks on apple varieties and bud sports of McIntosh apples, both by J. K. Shaw and L. Southwick; tree characters of fruit varieties, by Shaw, A. P. French, O. C. Roberts, and Southwick; genetic composition of peaches, by J. S. Bailey and French; soil management of apple orchards and effect of orchard mulches on plant nutrients of the soil, both by Shaw; testing of fruit varieties, by Shaw et al.; nature of winter hardiness in the raspberry, by R. A. Van Meter and French; storage of apples in modified atmospheres, by Southwick and Roberts; nutrition of highbush blueberries and blueberry culture, both by Bailey; premature dropping of McIntosh apples, by Southwick; and the use of lime and phosphorus in planting trees, ammonium sulfamate for killing weed trees and bushes, ethylene dichloride emulsion for the control of peach tree borers, and the use of sawdust as an apple tree mulch.

[*Horticultural studies at the University Station*] (*Agr. Expt. [Puerto Rico Univ. Sta.], 2* (1942), No. 3, pp. 1-2, 4-7, figs. 2).—This includes the following articles: *Cómo evitar y dominar las enfermedades en las hortalizas* [How to Avoid and Control the Diseases of Horticultural Plants], by L. A. Alvarez García (pp. 1-2); "La esponja vegetal o estropajo" [A Descriptive Account of the Vegetable Sponge], by J. I. Otero] (pp. 4-5); *La pomarrosa Malaya en la producción de vino* [The Malayapple (Ohia) for the Manufacture of Wine], by J. S. Simons and R. Arroyo (pp. 5-7); and *La guanábana y su cultivo* [The Sour sop and Its Culture], by J. S. Simons (pp. 7-8).

[*Horticultural studies by the Wyoming Station*] (*Wyoming Sta. Rpt.* 1941, pp. 30, 31-32, 33, 33-34).—Brief reports of work at the State experiment farms

are presented on the results of variety tests with small fruits at Afton, fruits, vegetables, and shelterbelt trees at Eden, irrigation experiments with gardens at Gillette, and treatment of chlorotic apple trees at Lander.

Use of "hormones" becoming an important tool in the growing of horticultural plants, A. M. BINKLEY (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 3, pp. 18-21, fig. 1*).—Information is given on the nature and use of various growth-promoting substances in plant propagation, control of fruit drop, etc.

Vegetable crop research has many practical angles (*Farm. Res. [New York State Sta.], 8 (1942), No. 3, pp. 4, 11*).—The research activities of the station in the production of canning crops are discussed. Among studies mentioned are those on the fertilization of vegetables, the use of starter solutions, rotation experiments, variety testing and breeding, and freezing preservation.

Purity, germination, and yield of some vegetable seeds offered for retail sale in Ohio in 1941, H. D. BROWN, C. N. MCINTYRE, E. DOLEZAL, and R. HEDGES (*Ohio Sta. Bul. 629 (1942), pp. [1]+29, figs. 2*).—The data presented, largely in tabular form, showed that vegetable seeds whether sold in packet or bulk form may differ greatly in varietal purity and in germinating and yield capacities. Many of the lots did not conform to the standards established by the State law. Cabbage seed tended to be badly mixed as to variety and even with other species, and radishes and tomatoes showed also considerable mixture. The most uniform plants were observed among the beans, both lima and green types. In fact, all of the lima bean lots were true to type.

Wisconsin canning pea trials, 1937-1941, E. J. DELWICHE (*Wisconsin Sta. Res. Bul. 144 (1942), pp. [2]+36*).—In trials conducted over 5 yr. in different locations in the State, information was obtained on the comparative yields and quality of a large number of varieties of canning peas. The highest yielding varieties on the average for all locations over the 5 yr. were as follows: Early kinds, No. 28,57 Alaska, Ace, and Wisconsin Early Sweet; midseason kinds, Canner King, Early Perfection, and Improved Penin; and late varieties, Wisconsin Merit, Stuart Perfection, and Perfected Wales. Early wrinkled-seeded varieties, similar in maturity and canning use to Surprise, outyielded in several instances Alaska sown on the same dates. Midseason and late varieties were about equal in yield, and both groups outyielded early varieties by a significant margin. On sandy soils, peas grown in rows compared favorably in yield with broadcast plantings. The quality of canned peas did not differ significantly between maturity groups, or for varieties within groups, provided the peas were harvested at identical stages of maturity. Observations following a frost in May 1938 showed that certain varieties are apparently superior in resistance to low temperatures.

Seek new ways to expedite the breeding of new fruits, B. R. NEBEL (*Farm Res. [New York State Sta.], 8 (1942), No. 3, p. 15*).—A survey is presented of recent progress with X-ray and chemical treatments of plant tissues to induce genetic changes.

The new Close apple, W. TOENJES (*Michigan Sta. Quart. Bul., 24 (1942), No. 4, pp. 321-322*).—A descriptive account is presented upon the growth, fruiting habits, and fruit of a very early-ripening apple developed by and named for the late C. P. Close of the U. S. Department of Agriculture. Eating quality is rated as good if the apples are picked while firm. The color was bright red on fruits exposed to sunlight.

Spraying for control of preharvest drop of apples, C. W. SCHNEIDER and J. V. ENZIE (*New Mexico Sta. Bul. 294 (1942), pp. 15, fig. 1*).—Naphthaleneacetic acid and naphthaleneacetamide used separately at the approximate concentration of 0.001 percent were effective in reducing the preharvest drop of sound

Stayman Winesap apples. Of the two materials, the former was the more effective. The duration of the effective period was about 10 days to 2 weeks, and from 2 to 3 days were required following spraying before the materials became effective. Two applications of naphthaleneacetic acid were more effective than one early treatment, but not significantly more effective than one late application in reducing dropping of Stayman Winesap apples in 1941. Both chemicals reduced the dropping of wormy Stayman Winesap apples, but not to the extent of appreciably increasing the number of wormy fruits to be handled during harvesting. In trials with Winesap, naphthaleneacetic acid appeared to reduce the dropping of both sound and wormy fruits.

Recherches sur la conservation des pommes et des poires [The storage of apples and pears], H. FAES, M. STAHELIN, and P. AUBERT (*Landw. Jahrb. Schweiz*, 56 (1942), No. 3, pp. 207-277, figs. 15; *Ger. abs.*, pp. 273-277).—Studies of the storage requirements of a number of important varieties led to the following general conclusions: Not over 24 hr. should intervene between the harvesting and storing of early-maturing varieties of pears and apples, and late varieties should be stored within a 10-day period following harvesting. The most favorable temperature for storing apples was between 35.6° and 39.2° F. At temperatures around 32° there was danger of browning of the flesh. The most favorable relative humidity ranged between 85 and 90 percent, and humidities below 80 percent tended toward shriveling and those above 95 percent to mildew. Waxing is recommended for certain varieties with rough skin, such as Boskoop and Canada Reinette. Specific recommendations are presented for the various apples and pears under study.

Blackberries merit more attention, G. L. SLATE (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, p. 1).—Due to various reasons, such as partial sterility of the flowers, susceptibility to disease and drought, thorns, and softness of the mature fruits, blackberry culture has declined in New York State. Fine flavor is obtained only in the fully ripe fruits. Eldorado is the only variety recommended for general culture in the State.

The blueberry in New York, G. L. SLATE and R. C. COLLISON (*New York State Sta. Cir.* 189, rev. (1942), pp. 29, figs. 7).—This is a revised edition of an earlier noted circular (E. S. R., 83, p. 340).

The influence of various soils on the growth and productivity of the highbush blueberry, S. JOHNSTON (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 307-310, figs. 2).—Plants of the Jersey blueberry, set in boxes containing different types and combinations of soil, responded very differently in growth and production. Plants in white sand alone or in reddish-colored underlying soil alone made very poor growth and produced very little fruit as compared with those in complete soil or in half surface soil and half white sand. In another trial in which plants were grown in soils of different pH values and different clay contents, it was evident that soil reaction was much more important than clay content. Apparently the highbush blueberry does not grow well in soils of a pH level greater than about 5.2.

Methods of splitting hevea seedlings, H. F. LOOMIS. (U. S. D. A.). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 2, pp. 97-124, figs. 19).—Tests of the Ramaer and Gambar methods of dividing hevea seedlings indicated that the latter method gives the better results, as measured by more vigorous plants and shorter time required. Splitting of seedlings from which the main stem had been cut off just above the cotyledon bud resulted usually in the production of twin cotyledon plants that were equal to those produced from cotyledon sprouts of Gambar sections but not to those produced from main-stem sections. A method of direct planting of split seedlings without the necessity of digging them for

separation and transplanting is described. The division of seedlings from 10 days to 15 mo. old was attempted, and fair success was obtained with younger plants, pointing to the possibility of increasing the number of plants by splitting seedlings 3 or 4 mo. of age.

Trials of annual flowers, 1941, E. I. WILDE, C. B. LINK, and J. R. CULBERT (*Pennsylvania Sta. Bul. 426 (1942), pp. [2]+52, figs. 5*).—Information is presented on the results of extensive tests of various annual flowering plants, especially marigolds. Descriptive notes on the varieties are presented in tabular form.

Blooming dates of some selected hardy perennials, H. S. TIFFANY (*Massachusetts Sta. Bul. 392 (1942), pp. 55*).—In tabular form data are presented on the blooming period, color of the flowers, and the plant height of a selected list of hardy perennials. To facilitate the selection of a succession of flowers, the material is arranged in three groups—spring, summer, and fall flowers.

Tulip bulb production in the Upper Peninsula, P. KRONE, J. G. WELLS, and P. BOWSER (*Michigan Sta. Quart. Bul., 24 (1942), No. 4, pp. 280-287*).—Trial plantings of tulip bulbs at Chatham and Jacobsville indicated the possibilities of successful culture in the Upper Peninsula, with yields comparing very favorably with those obtained in the Kalamazoo area. Weight increases varied from 2.3 to 5.07 times the weight of the original bulbs planted. The general quality of the bulbs was excellent, and preliminary forcing trials indicated that they would force satisfactorily.

Care of damaged shade trees, R. P. MARSHALL (*U. S. Dept. Agr., Farmers' Bul. 1896 (1942), pp. II+34, figs. 23*).—Superseding Farmers' Bulletin 1726 (E. S. R., 72, p. 628), this contains information on the causes of tree wounds and how they may be avoided, healing and treatment of wounds, types of wounds requiring special treatment, repairs to damaged trees, etc.

The planting and maintenance of lawns, D. G. STURKIE and H. S. FISHER (*Alabama Sta. Cir. 85 (1942), pp. 20, figs. 16*).—General information is presented on the selection of grasses and ground covers, preparation of the soil designed for a lawn, establishment of lawns by seeding and by sodding, care and maintenance of lawns, and the control of weeds, insects, diseases, and various other pests.

FORESTRY

[Forestry studies by the Connecticut State Station] (*Connecticut [New Haven] Sta. Bul. 452 (1942), pp. 24-25*).—Among studies by M. F. Morgan et al., the progress of which is noted, are the effect of soil types on the root development of forest trees, the nutritional requirements of forest nursery stock, and the effect of different methods of slash disposal on the soil and on the growth of trees.

Trees of Puerto Rico, I. L. R. HOLDRIDGE (*U. S. Dept. Agr., Forest Serv., Trop. Forest Expt. Sta. Occas. Paper 1 (1942), pp. [2]+105, figs. 50*).—In this first of a projected series descriptive information is presented on 50 species.

Tree growth and the environmental complex: A critique of "ring" growth studies, with suggestions for future research, A. W. SAMPSON and W. S. GLOCK. (Univ. Calif. et al.). (*Jour. Forestry, 40 (1942), No. 8, pp. 614-620*).—This report of a conference held at the University of California in August 1941 places much emphasis on the complexity of environmental factors influencing tree growth and on the biometric difficulties involved in attempts to correlate tree growth with rainfall. It was agreed that extensive experimental studies under controlled conditions are needed and that the cooperation of plant physiologists, ecologists, climatologists, soil scientists, etc., is essential.

Parthenocarpy, parthenogenesis, and self-sterility of Douglas fir, G. S. ALLEN (*Jour. Forestry*, 40 (1942), No. 8, pp. 642-644).—Controlled experiments in British Columbia indicated that the Douglas fir may be highly self-sterile and that parthenogenesis may occur to a limited extent. Since neither pollination nor fertilization had any apparent effect on the growth of the cones, examination of the seeds is the only way to determine the results of pollination. Parthenocarpy is a normal condition in the species, and the seeds are usually empty. Abortions of immature conelets were nonexistent in the bagged series, with the evidence indicating that the critical period is the time of bud bursting and emergence of the conelet. Cross-pollination is evidently one of the major factors influencing seed quality in the Douglas fir.

Will girdling always kill Douglas fir? T. J. STARKER. (Oreg. State Col.). (*Jour. Forestry*, 40 (1942), No. 8, pp. 658-659).—The fact that certain trees survived for 13 yr. following complete girdling is ascribed to natural root grafts with nearby ungirdled trees.

Effect of soil aeration on the foliation of black locust seedlings, T. S. COILE and R. N. GAISER (*Jour. Forestry*, 40 (1942), No. 8, pp. 660-661, fig. 1).—Tests made of the effects of aerating A and B horizons of three Piedmont soils of black locust seedlings showed a significantly greater number of plants foliated in horizon A than in horizon B. However, the rate of foliation did not prove to be different for the horizons. Plants growing in aerated soils showed significantly higher foliation than those in nonaerated, and the production of leaflets in the aerated soils progressed significantly faster than in the non-aerated soils.

On the range of Shumard red oak (*Quercus shumardii* Buckl.), H. H. CHISMAN. (Pa. State Col.). (*Jour. Forestry*, 40 (1942), No. 8, p. 658).—Information is presented on the northern limits of the species.

Propagation of a rapid growing semi-evergreen hybrid oak, W. S. FLORY, JR., and F. R. BRISON (*Texas Sta. Bul.* 612 (1942), pp. 32, figs. 11).—Of various methods employed in an attempt to propagate some desirable oaks (known as Ness hybrids) obtained by the station from crosses of the live oak *Quercus virginiana* and *Q. lyrata*, whip and bark grafting on compatible stocks were most successful. A wide series of treatments of cuttings taken from the original 30-year-old hybrids gave negative results. Cleft grafting was only moderately successful, due apparently to the difficulty of obtaining good fits with large caliber wood. As to stocks, the results indicated that these hybrid oaks may be successfully grafted on various white oak stocks. Black oak species, on the other hand, were generally incompatible.

Combining the Christmas tree plantation and livestock pasture on cut-over lands of good fertility, A. BERRIDGE (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 277-280, fig. 1).—In a 13-yr. trial of a combination of pasture and white spruce planting the results suggested that such a combination is a satisfactory method for producing Christmas trees and at the same time some pasture returns. The livestock ate the competing grasses and, so long as there was an abundance of green pasture, caused no material damage to the trees. The combined returns from trees and pasturage yielded a very satisfactory net income.

Estimating volume on the spot; J. W. MACON and S. R. GEVORKIANTZ. (U. S. D. A.). (*Jour. Forestry*, 40 (1942), No. 8, pp. 652-655, figs. 3).—A tally form, combining the functions of both tally sheet and volume table, is presented as a practical method for making rapid and reliable estimates of timber volume directly in the forest.

DISEASES OF PLANTS

The Plant Disease Reporter, [August 1 and 15, 1942] (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 26 (1942), Nos. 14, pp. 305-316, figs. 4; 15, pp. 317-340, figs. 6).—In addition to the host-parasite check-list revision, by F. Weiss (Nos. 14, *Salix* concluded, and 15, *Samanea* to *Sassafras*), the following are included:

No. 14.—Bacterial leaf spot (*Phytophthora viburni*) of *Viburnum*, by H. W. Anderson and H. H. Thornberry; bacterial ring rot of potato in Arizona, by W. G. Hoyman; and brief notes on potato late blight in New York, bacterial blight of Persian walnut in New York, and dodder on petunia.

No. 15.—Incidence of ear rots in the 1941 corn crop, by N. E. Stevens; miscellaneous notes (mostly North Dakota) on diseases of cereals and grasses, and diseases of vegetable crops and ornamentals, by R. Sprague; cereal diseases in North Central States, by H. O. Putnam; some fruit diseases in Pennsylvania, including cherry viruses, powdery mildew on cherry, *Cylindrosporium* leaf spot on red raspberry, fire blight (with tabulation of blossom blight on apple trees in central Pennsylvania 1942), and brown rot on wild plum, by G. L. Zundel; a lethal virus disease of cantaloup occurring in the Imperial Valley, by J. T. Middleton and T. W. Whitaker; notes on some diseases of ornamentals, including *Colletotrichum trichellum* on stems of *Hedera helix*, stem canker and foot rot of *Vinca minor*, and top blight of rhododendron, by F. Weiss; reports on potato late blight from Massachusetts, New York, Virginia, Minnesota, and Iowa; recent observations on diseases of truck crops, potato, and tobacco in Massachusetts, by O. C. Boyd; and brief notes on wheat nematode spread in South Carolina, two diseases (*Bacterium papavericola* and *Sclerotinia sclerotiorum*) of poppy in Oregon, and bean anthracnose very severe in Virginia.

Index to Supplements 121-128, N. W. NANCE (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1940, Sup. 129, pp. 379-403).

Report of the 1942 annual meeting of the southern division of the American Phytopathological Society (*Phytopathology*, 32 (1942), No. 7, pp. 647-651).—Abstracts of 15 papers on plant diseases and/or their control are included.

[**Plant disease studies by the Arizona Station**]. (Partly coop. U. S. D. A.). (*Arizona Sta. Rpt.* 1941, pp. 7, 79-81, 82-87, figs. 3).—Brief reports are given on studies of boron toxicity to crops, including grapefruit; bacterial wilt of alfalfa; bacterial necrosis of the giant cactus; dry root rot of citrus associated with *Fusarium* spp.; *Alternaria* infection of cotton bolls; cotton stubs, seed, and wind as sources of black arm-angular leaf spot infection; southern *Sclerotium* wilt and root rot of cotton; cotton rust (*Puccinia schedonnardi*) incidence; effects of various chemicals on the growth of *Sclerotinia sclerotiorum*; control of *Phymatotrichum* root rot of pecan trees; potato bacterial ring rot in Arizona; damage by race 56 of wheat stem rust; and plant parasites new to the State.

[**Phytopathological studies by the Connecticut [New Haven] Station**]. (Partly coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul.* 452 (1942), pp. 12, 15-16, 19-22, 27).—Brief reports of progress by R. B. Friend, W. O. Filley, J. G. Horsfal, P. J. Anderson, et al., are presented on control of white pine blister rust; *Alternaria* defoliation of tomatoes; fungicidal control of apple scab; meeting the fungicide shortage; Dutch elm disease pathogenesis and control; chemotherapeutic trials with yellow-red virosis (X disease) of peach; and chemistry of "black" tobacco, and downy mildew control in seedbeds.

[Phytopathological studies by the Florida Station] (*Florida Sta. Rpt. 1941*, pp. 56, 71-72, 93-97, 101-118, 123, 139-141, 170, 171-172, 175-176, 180, 184-185, 195, 196, 200-204, figs. 9).—Brief summaries of progress, by J. P. Camp, J. R. Watson, H. E. Bratley, W. B. Shippey, L. H. Rogers, R. A. Carrigan, A. N. Brooks, D. G. A. Kelbert, G. F. Weber, R. K. Voorhees, M. N. Walker, W. B. Tisdale, G. D. Ruehle, K. W. Loucks, E. West, L. O. Gratz, A. H. Eddins, G. R. Townsend, and R. R. Kincaid, are presented on sulfur dusting of peanut for *Cercospora* leaf spot; root knot control by selection of resistant host plant strains, mulching, and rotation; seed and seedbed treatments for celery and other vegetable diseases; control of early (*Cercospora*) and late (*Septoria*) blights of celery; control of lettuce downy mildew; control of fungus leaf and stem diseases, *Fusarium* wilt, and late blight (*Phytophthora*) of tomato, and field observations on other diseases of this crop; dusting for downy mildew of cucumbers; calcium cyanamide for strawberry bud nematode; comparative study of *Diplodia* forms resembling *D. frumentii*; investigation and control of *Fusarium* wilt and other fungus diseases, and an abnormal auxiliary proliferation in watermelon; bark disease of Tahiti lime trees; fruit rots of grape; host relations and factors influencing the growth and parasitism of *Sclerotium rolfsii*; causes of failure of vegetable seed and seedlings in various Florida soils and development of preventive methods; *Phomopsis* blight and fruit rot of eggplant; *Ovulinia* flower spot of azalea; camellia dieback disease; zinnia leaf spot and mildew; potato disease control, including bacterial ring rot, scab, spindle tuber and leaf roll, and early and late blights; potato rot found due to *Xylaria apiculata*; investigations and control of bacterial brown rot of potato and related crops; control of *Rhizoctonia* diseases of potato and vegetable crops; a "healed holes" condition of potato tubers of suspected insect origin; "striped dwarf" of corn; fungicidal and ethylene chlorohydrin treatments of seed potatoes; vapo-dusting of potatoes, celery, tomatoes, and beans; bean breeding in relation to rust and powdery mildew resistance; cabbage dusting and spraying for downy mildew and black rot and seed treatments for damping-off; citrus scab and its control; melanose and stem-end rots of citrus fruits; hard spots or gum pockets in grapefruit rinds controlled by borax sprays; tobacco varieties resistant to black shank and root knot; tobacco downy mildew control; culture practices for reducing root knot infestation of tobacco; zinc deficiency, scab, and dictyospermum scale, and fruit blotch and black spot of avocado; poinsettia scab; and mineral deficiencies of loquat, orange jessamine, and pitanga (*Eugenia uniflora*).

[Plant disease work by the Kentucky Station] (*Kentucky Sta. Rpt. 1941*, pp. 13-17).—Brief reports are presented on tobacco disease control by the development of resistant varieties, including White Burley Ky. 16 resistant to root rot and Ky. 33 resistant to *Fusarium* wilt, and mosaic-resistant strains for burley and dark tobacco; a virus disease of burley tobacco shown to be due to the *Plantago major* virus; certain legume viruses found transmissible to tobacco; phosphorus starvation causing leaf spotting of tobacco, and sources of bacterial leaf spot infection.

[Phytopathological studies by the Massachusetts Station]. (Partly coop. U. S. D. A.). (*Massachusetts Sta. Bul. 388* (1942), pp. 15-18, 21-28, 78).—Brief reports are presented, by C. V. Kightlinger, M. A. McKenzie, A. V. Osmun, W. L. Doran, E. F. Guba, C. J. Gilgut, H. E. White, L. H. Jones, and H. S. Tiffany, on studies of tobacco black root rot, brown root rot, and soil treatments for damping-off and weeds in the seedbed; the Dutch elm disease in the State, its spread by *Scolytus multistriatus*, and its control; other diseases of elms and other trees and the importance of tree disease studies in relation to national defense; damping-off and growth of seedlings and cuttings of

woody plants as affected by soil treatments and environal modification; diseases of ornamental herbaceous plants due to soil-infesting organisms and their control; chemical soil-surface treatments in hotbeds for controlling damping-off of early forcing vegetables; susceptibility of *Lycopersicum* spp. to *Cladosporium* leaf mold; causes and control of decay in stored squashes; *Phomopsis* stem canker of gardenia; disease resistance and heredity in carnations; apple scab control; copper dusts for cucumber and muskmelon; mercurials for crucifer club root control; vegetable seed treatments for damping-off control; effect of vitamin B₁ at different soil temperatures on gardenia chlorosis; and powdery mildew on garden phlox.

Parasitic fungi of Wisconsin, J. J. DAVIS (*Madison, Wis.: Democrat Ptg. Co., 1942, pp. [1]+157*).—This posthumously published list constitutes a record of collections in the University of Wisconsin herbarium and in the author's personal herbarium, also located at the University of Wisconsin. It comprises a compilation of various previously published reports, including A Provisional List of Parasitic Fungi in Wisconsin.¹ Indexes to hosts and fungi are provided. The foreword is by E. M. Gilbert.

Twenty-first annual report of the Canadian Plant Disease Survey, 1941, I. L. CONNERS (*Canada Dept. Agr., Sci. Serv., Plant Disease Survey Ann. Rpt., 21 (1941), pp. [1]+XVIII+102*).—The same general plan is followed as in previous reports (E. S. R., 86, p. 490).

Plant pathology.—Progress report for the season 1939-40, G. M. WICKENS (*Empire Cotton Growing Corp., Expt. Stas. Prog. Rpts., 1940-41, pp. 43-64, fig. 1*).—On diseases and insect pests of the cotton boll, with brief notes on *Verticillium* wilt of cotton and *Fusarium* wilt of sunn hemp.

The genus *Cerebella* Cesati—its biologic status and use, R. F. LANGDON (*Phytopathology, 32 (1942), No. 7, pp. 613-617*).—The literature on this genus is reviewed, and further evidence is presented to show that its members are saprophytic on carbohydrate-rich materials, the commonest substratum for the fungus being the sugary honey-dew secretion associated with the *Sphacella* stage of *Claviceps* spp. The need for a revision of the species of *Cerebella* is pointed out. Four points arise from a knowledge of the relation between *Cerebella* and the plants on which it is found—(1) the name should be removed from the host indexes and *Sphacella* substituted, (2) *Cerebella* provides a natural control of ergot by inhibiting the development of sclerotia, (3) it is a good field indicator of the presence of ergot, and (4) the history of ergot in a country may be traced through old records of *Cerebella* on grasses.

Nuclear phenomena involved at meiosis in *Coleosporium helianthi*, L. S. OLIVE. (Univ. N. C.). (*Jour. Elisha Mitchell Sci. Soc., 58 (1942), No. 1, pp. 43-51, pls. 2*).—A cytological study of this rust, common in the North Carolina area, with its uredinial and telial phases on *Helianthus* spp. and its aecia and pycnia on *Pinus echinata* and *P. virginiana*.

Cuatro nuevos Deuteromicetos Colombianos [Four new Colombian Deuteromycetes], R. OBREGÓN BOTERO (*Caldasia, No. 3 (1941), pp. 49-51, fig. 1*).—Four new leaf-parasitizing species of *Cercospora* are described.

Cross inoculations with isolates of *Fusaria* from cotton, tobacco, and certain other plants subject to wilt, G. M. ARMSTRONG, B. S. HAWKINS, and C. C. BENNETT. (S. C. Expt. Sta. Coop. U. S. D. A.). (*Phytopathology, 32 (1942), No. 8, pp. 685-698*).—Inoculations with the wilt *Fusaria* from *Cassia tora*, cotton, tobacco, okra, tomato, watermelon, and cowpea were made chiefly by a solution-culture technic, though some soil inoculations were also used. The isolates from cotton, okra, *Cassia*, and tobacco from South Carolina and

¹ Wis. Acad. Sci., Arts, and Letters, Trans., 17 (1914), pt. 2, No. 2, pp. 846-984.

Kentucky caused wilt with these various hosts, one fungus apparently being involved. A susceptible burley tobacco was attacked, but a flue-cured variety (Gold Dollar) showed little or no wilt. Tobacco isolates from Maryland, however, caused wilting of both the burley and the flue-cured tobacco, but not of cotton or okra. The weed *C. tora*, found growing in cotton fields, was attacked by the cotton-wilt fungus. The tomato, watermelon, and cowpea fungi are probably pathogenic only to their respective or closely related hosts, since the tomato fungus did not cause wilt of watermelon, okra, or cotton, the watermelon fungus did not cause wilt of tomato, and the cowpea fungus attacked neither cotton nor *Cassia*. There are 19 references.

Life history and taxonomy of the fungus *Physalospora rhodina*, R. K. VOORHEES (*Florida Sta. Bul.* 371 (1942), pp. 91, figs. 16).—Continued collection and study of different forms of this complex and variable group (*Diplodia* and related genera) on different tropical and subtropical host plants has convinced the author that, primarily, different forms or physiologic races of only a few specific fungi are being dealt with. The large number of destructive diseases and the wide geographical and host distribution of the many forms considered has led to a multiplicity of names, many of which might well be included under one binomial. The main purpose of this study was therefore to demonstrate that the collections of *Diplodia* from different tropical and subtropical hosts made by the author and others should be included under *P. rhodina*. Of the several hundred single-spore isolates of *P. rhodina* from southern United States and other tropical or subtropical sources, about 100 were studied in detail, the results indicating an indefinite number of races very similar in appearance but often differing in one or more characters. It became clear that many of these races arise in the sexual stage in nature. Practically all of them were differentiated by aversion reactions in culture, and often also by growth and growth rate, pigmentation, and perithecial type. It was shown that the factor or factors for sex are carried by the ascospores in different ratios in the ascus. The general morphological characters of the conidial and perithecial collections are described. Certain races showed slight differences in pathogenicity but no definite host specialization. The morphological differences among the many conidial collections of *P. rhodina* studied are not considered wide enough to merit specific distinction. These isolates and certain forms described by others as distinct species are therefore included in the synonymy of *P. rhodina*. There are at least three distinct species of *Physalospora* that are not distinguished by their *Diplodia* stages. Hence it is entirely possible that many of the *Diplodia* forms included under *P. rhodina* may have their sexual stages in undescribed species of *Physalospora* and other genera. There are 86 references.

The Plasmodiophorales, including a complete host index, bibliography, and a description of diseases caused by species of this order, J. S. KARLING (*New York: Author*, 1942, pp. IX+144, figs. [648]).—Following the introduction (including glossary and bibliography), the individual chapters deal respectively with the cytology, sexuality and alternation of generations, classification and description of species, phylogeny and relationships of the order, and diseases caused by specific members of the group.

A new *Rozella* of the polysporangiate series, L. SHANOR. (*Univ. Ill.*) (*Jour. Elisha Mitchell Sci. Soc.*, 58 (1942), No. 1, pp. 99-101, pl. 1).—*R. achlyae* n. sp., parasitizing *Achlya flagellata* (Phycomycetes) is described and illustrated.

A further note on the nitrogen metabolism of *Stereum gausapatum* Fries, J. A. HERRICK and C. J. ALEXOPOULOS (*Ohio Jour. Sci.*, 42 (1942), No. 3, pp. 109-111).—In continuation (*E. S. R.*, 83, p. 636), it was found that growth on media containing peptone, asparagine, or $-\text{NH}_4$ ions as the only source of N

is greatly increased by adding minute amounts of thiamin. With NH_4NO_3 growth was roughly proportional to the thiamin content of the medium. Growth on media containing only $-\text{NO}_3$ ions as N sources was negligible, even with thiamin present. Lack of growth in such cases was shown not to be due to toxicity. This fungus is therefore able to use asparagine and NH_4 salts, in addition to peptone, as sources of N, the thiamin content acting as a limiting factor.

Lipolytic activity of phytopathogenic bacteria determined by means of spirit blue agar and its taxonomic significance. M. P. STARR and W. H. BURKHOLDER. (Cornell Univ. et al.). (*Phytopathology*, 32 (1942), No. 7, pp. 598-604).—The comparative abilities of 206 cultures (65 species and varieties) of phytopathogenic bacteria (genus *Phytomonas* Bergey et al.) to decompose cottonseed oil were determined by this method. Its value as a taxonomic character was indicated by the fact that each of the recognized groups of this heterogeneous genus has a characteristic reaction on spirit blue-cottonseed oil agar. Of 24 species and varieties of *Xanthomonas* (members of the "*P. campestris* group"), 21 were actively lipolytic by this procedure; of 27 green-fluorescent pigment-producing phytopathogenic *Pseudomonas* species, only 4 were lipolytic; and of the tested species of phytopathogenic *Corynebacterium* ("gram-positive group"), of the gall-forming "*Phytomonas tumefaciens* group," or of the miscellaneous "*P. stewartii* group," none were actively lipolytic by this method. The taxonomy and nomenclature of the plant-pathogenic bacteria are discussed, particularly in the light of this study.

A simple technique for aseptic handling of media. J. A. HERRICK (*Phytopathology*, 32 (1942), No. 7, pp. 636-637).—The simple technic outlined is suggested especially for use in cases where equipment is very limited or where it is impracticable to set up more elaborate apparatus.

Coacervates in physical and biological systems. J. DUFRENOY and H. S. REED. (Univ. Calif.). (*Phytopathology*, 32 (1942), No. 7, pp. 568-579, figs. 6).—Coacervate formation in vacuoles of hypoplastic cells is believed due to a change in equilibrium between the diffused colloidal material and the surrounding liquid. The globular coacervated aggregates consist of a central mass of phenolic material surrounded by a layer of phospholipoids. These coacervates occurred only in abnormal cells of orange and sunflower plants deprived of Zn or other essential trace elements. Equilibrium change may be so abrupt as to allow no time for complete outward diffusion of the vacuolar sap, a portion of which is imprisoned as "vacuoles" within the coacervate. Cellular hypoplasia was also indicated by starch accumulation in the plastids, by filiform mitochondria, and, in extreme cases, by lysis of the cell contents. Under disease conditions plastic materials were used not for plant maintenance but in forming coacervated aggregates in the cell vacuoles.

Catechol aggregates in the vacuoles of cells of zinc deficient plants. H. S. REED and J. DUFRENOY. (Univ. Calif. and La. State Univ.). (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 544-551, figs. 8).—Knowledge of the cellular inclusions apparently characteristic of many diseased cells is advanced by new developments in technic here outlined. These spherical inclusions in cell vacuoles of Zn-deficient plants are said to be formed by a process in which some of the colloidal material in the vacuolar solution becomes condensed into a spherical mass instead of being distributed at random in the solvent. These aggregates may be formed by a process of coacervation, which to a certain extent may be considered a separation of phases. However, they have a boundary layer which is more than the theoretical interphase, being a precipitation membrane composed of oriented molecules. In the cases studied, the mass of the aggregates appeared to be made up of catechol, and the precipitation membrane or

bounding layer was a phospholipoid, identifiable by suitable chemical reagents. Coacervated aggregates were found in the vacuoles of hypoplastic cells of leaves and in the postmeristematic cells of growing shoots of apricot trees with the little leaf Zn deficiency, as well as in leaf cells of walnut trees with the same malady. Evidence of a pathological condition in the walnut leaves was also indicated by the escape of necrotic material from the cells and its accumulation in intercellular spaces, coupled with gum formation in these spaces adjoining severely affected cells. There are 24 references.

Symptoms of zinc deficiency in wheat and flax, C. R. MILLIKAN (*Jour. Austral. Inst. Agr. Sci.*, 8 (1942), No. 1, pp. 33-35, figs. 3).—The symptoms are described and illustrated, with the literature briefly reviewed.

Seed and soil treatment for the control of damping-off, L. H. PERSON and S. J. P. CHILTON (*Louisiana Sta. Bul.* 349 (1942), pp. 16).—In a 7-yr. study on the Sharkey and Olivier soils of the State, red copper oxide for seed treatment proved the most practical and effective material tried for controlling damping-off of tomatoes and bell peppers, but that on the seed was not sufficient to control post-emergence damping-off of eggplants. Vasco 4 and zinc oxide gave best results with cabbage, but red copper oxide was toxic. Soil treatments with commercial formaldehyde were about as efficient as red copper oxide seed treatments on tomatoes and bell peppers but were of little value with eggplants. Zinc oxide, Vasco 4, and yellow copper oxide as soil surface treatments were about equally effective against post-emergence damping-off of eggplants. Concentrated formaldehyde solution (40 percent) diluted in five or six times its volume of water was effective against damping-off of tomatoes, peppers, and eggplants but proved toxic to the last named on Olivier soil. Seed treatment of ornamentals by yellow copper oxide was most efficient, followed in order by red copper oxide, Vasco 4, and zinc oxide. The organic mercury dusts were often toxic when applied full strength. Specific recommendations for various crop and ornamental plants are given.

Use of fungicides in war-time, W. B. TISDALE (*Fla. Expt. Sta.*). (*Citrus Indus.*, 23 (1942), No. 7, pp. 13, 18).

Diseases of British grasses and herbage legumes, K. SAMPSON and J. H. WESTERN (*Cambridge, Eng.: Univ. Press*, 1941, pp. VII+85, pls. 8, figs. 15).—This handbook includes sections on the diseases of grasses, turf, and herbage legumes, with a short account of mineral deficiencies. A host-parasite index and bibliography of over 13 pages are provided.

Sterilization technique for grass seeds, R. B. STEPHENSON (*Univ. Ill.*). (*Plant Physiol.*, 17 (1942), No. 2, pp. 324-325).—Lettuce, cantaloup, and pea seed were sterilized without injury by soaking for 2 hr. in a saturated solution of Semesan and then passing through a 5 percent solution of bromine water. This procedure, however, was lethal to Kentucky bluegrass seed, as were all tested compounds containing Hg. An adequate sterilization without injury to germination was obtained by pretreatment of the grass seed with alcohol followed by Ca hypochlorite.

Thiuram disulfide for turf and for treating seeds, P. P. PRONE (*New Jersey Stas. Nursery Disease Notes*, 14 (1942), No. 10, pp. 36-39).—In this progress report, very promising results are noted in the control of brown patch (*Corticium solani*) and dollar spot (*Sclerotinia homeocarpa*) on creeping bent grasses by use of thiuram disulfide (T. M. T. D.).

The effect of light and temperature on the viability of urediospores of certain cereal rusts, L. HWANG (*Phytopathology*, 32 (1942), No. 8, pp. 699-711).—At intervals during exposure, germination tests were made of the viability of urediospores of several races of *Puccinia coronata*, *P. graminis tritici*, *P. graminis*

secalis, and *P. rubigo-vera tritici*, which had been evenly distributed on white papers in petri dishes and exposed to direct sunlight and to different temperatures. Other things being equal, as the light intensity increased the loss of viability was more rapid. At moderate temperatures some spores remained viable for about a month at light intensities of 500–1,500 footcandles, but for only 12 days at 1,000–7,000 footcandles. Viability was lost most rapidly at high temperatures, but a few spores germinated after exposure to 60° C. for 15 hr. and 8 percent germinated after exposure to 44° for 60 hr. Urediospores dusted over dry surfaces of plants exposed to direct sunlight survived for at least 4 days and caused infection when moisture was supplied at that time. There were no consistent differences in urediospores produced in the field or in the greenhouse, in full light or in half shade, or in those produced early in the life of the uredium and those produced a week later. There are 22 references.

The influence of storage in contact with certain seed-pickling dusts on the germination of grain, D. C. WARE (*Jour. Austral. Inst. Agr. Sci.*, 8 (1942), No. 1, pp. 22–25).—In the experiments reported, wheat and barley seed grain was stored in closed containers in contact with fungicidal dusts (6 mercurial, 1 S, and 2 Cu dusts). No injury to germinability was noted on barley seed stored with any of the dusts used (the one most damaging to stored wheat not included). The germinability of seed wheat was improved by most of the dusts, but certain ones, and more especially those containing ethyl mercury phosphate, caused a depression at 20° C. storage, amounting in one case to 25 percent.

Studies on black stem of alfalfa caused by *Ascochyta imperfecta*, M. L. PETERSON and L. E. MELCHERS. (*Kans. Expt. Sta. coop. U. S. D. A.*). (*Phytopathology*, 32 (1942), No. 7, pp. 590–597, figs. 3).—Black stem, occurring in Kansas and causing destructive defoliation and discoloration of the alfalfa hay crop, was traced to *A. imperfecta*. It probably overwinters as dormant mycelia and pycnidia in crop residues, from which infection takes place during rains the following spring. The optimum temperature for growth in culture was 21° C., with slight growth at 9° and very little at 33°. Pycnidia were produced at 9°–30°, but were most abundant at 27°. Spore suspension inoculation revealed no relationship between age of alfalfa leaves and severity of infection. *Medicago falcata* and *M. ruthenica* were added to the host range.

A nonpathogenic buff-colored barley smut, W. M. BEVER. (Idaho Expt. Sta. coop. U. S. D. A.). (*Phytopathology*, 32 (1942), No. 7, pp. 637–639, fig. 1).—Two heads of a buff-colored smut from an F₁ of *Ustilago hordei* × *U. nigra* were collected from a plant of Nepal (C. I. 595) barley. Except for color, these heads were identical with those containing the usual black chlamydospores of *U. hordei*. The spores were glabrous and hyaline, and the germination was typical of the sporidium-forming smuts. Sporidium fusion in culture revealed two sex groups. However, pathogenicity tests failed to produce smut on susceptible hosts. The factors here governing sex and pathogenicity are thus believed to be different.

The relative effect of environmental and genetic factors on growth types of *Ustilago zaeae*, M. F. KERNKAMP. (Minn. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 7, pp. 554–567).—It was found that single sporidial lines of corn smut on artificial media may consist entirely of sporidia or of mycelium, or of varying proportions of each. Neither the strictly sporidial nor the strictly mycelial lines were found to be changed appreciably by nutrients, plant extracts, silage extract, manure extract, growth substances, poisons, dyes, O₂ supply, or osmotic concentration of the medium. The intermediate lines produced varying amounts of sporidia or mycelium, depending on the effect of environmental factors, but in general the sporidial type predominated in intermediate lines when conditions favored rapid growth, and the mycelial type predominated when conditions

were unfavorable. Abundant nutrients, particularly sugars, proved especially effective in inducing sporidial growth. In the progeny of a cross between strictly sporidial and strictly mycelial lines, there was clear-cut segregation for growth type. Progenies of crosses between predominantly sporidial intermediate lines yielded mostly sporidial segregates, and vice versa. It proved impossible, however, to cross strictly sporidial lines, since plants inoculated with combinations of such lines failed to become infected and examination of the plants indicated that no mycelium was formed. It would seem, therefore, that some lines have only the genetic factors for sporidial propagation and others only for mycelial growth, and the limits of variability imposed by the genes are very narrow. Most lines, however, have genes that permit either sporidial or mycelial growth, and environmental factors determine which will preponderate.

Insect transmission of wallaby ear disease of maize, A. J. SCHINDLER (*Jour. Austral. Inst. Agr. Sci.*, 8 (1942), No. 1, pp. 35-37, fig. 1).—It is shown that this disease is transmissible by jassids, and *Cicadula bimaculata* is said to be mainly responsible, with *Peregrinus maidis* probably also involved.

Rhizoctonia infection of cotton and symptoms accompanying the disease in plants beyond the seedling stage, D. C. NEAL (U. S. D. A. and La. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 7, pp. 641-642, fig. 1).—Note on injury to older plants.

On the cause of the milo disease, L. E. MELCHERS. (Kans. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 7, pp. 640-641).—According to previous investigations, the cause of the root, crown, and shoot rot, or *Pythium* root rot, of milo, more commonly known as the "milo disease," has been ascribed to *P. arrhenomanes*. In this preliminary report, the author states that his more recent studies indicate that this fungus cannot be the sole causal factor, but that certain other organisms, environmental conditions, or extenuating factors other than those originally studied are also etiologically involved.

Field studies of smut resistance in oats, T. R. STANTON and H. C. MURPHY. (Iowa Expt. Sta. coop. U. S. D. A.). (*Jour. Amer. Soc. Agron.*, 34 (1942), No. 3, pp. 248-258).—In each case using local smut collections, uniform tests of oats for resistance were conducted over 5 yr. at 9-15 stations each year. The Canadian and Gothland varieties underwent high infection by nearly all smut collections, averaging over 73 and 86 percent, respectively. Comparable percentages for the other check varieties (Richland, Monarch, Black Mesdag, Fulghum, and Applier) ranged from 0.56 to nearly 21 percent. Navarro and Victoria were entirely free from infection throughout. Markton showed an average of 1.68 percent in 1935, but was free in the other years. Bond showed some infection in all years due to its susceptibility to the specialized races attacking Red Rustproof strains. Of the 68 varieties and selections considered as having resistance to smut, 23 were free from infection throughout the tests. In general, the amount of infection for most years was very low for nearly all varieties and strains tested, only 18 exhibiting an average exceeding 1 percent. Of the various groups of selections, that from the cross between Victoria and Richland proved most resistant. The Bond crosses were the most susceptible of any group of resistant selections. There are 15 references.

Potato diseases in Montana and their control, H. E. MORRIS and M. M. AFANASIEV (*Montana Sta. Cir.* 166 (1942), pp. 41, figs. 23).—This handbook describes and illustrates some of the common potato diseases occurring in the State and suggests measures which may be taken to reduce the losses therefrom. Included are diseases due to fungi, bacteria, and viruses, psyllid yellows, and nonparasitic diseases and injuries.

A new form of low-temperature injury in potatoes, M. T. HILBORN and R. BOND. (Maine Expt. Sta.). (*Amer. Potato Jour.*, 19 (1942), No. 2, pp. 24-29,

fig. 1).—A so-called "mahogany rot," here named "internal mahogany browning," was found to be caused by long exposure to medium low temperature. Chippewas and Katahdins stored at 32° F. through the winter exhibited the discoloration by March, but no injury appeared in these varieties stored at 38°, or in Green Mountain at 32°. Leaf roll aggravated the injury in Chippewas. Exposure to low temperatures for short periods produced the usual freezing injury in all varieties tested. This injury occasionally exhibited a fluorescence, but it was more bluish than the greenish tinge of internal mahogany browning. Leaf roll accentuated the greenish fluorescence, so that it was indistinguishable from that of bacterial ring rot tubers. Internal mahogany browning may reduce the stand and yield of a field planted with seed stock showing the injury.

A contribution to pathological anatomy of rice plants affected by *Gibberella fujikuroi* (Saw.) Wollenweber, I, Y. NISIKADO and K. KIMURA (*Ber. Ōhara Inst. Landw. Forsch.*, 8 (1941), No. 4, pp. 421-426, pls. 2, figs. 2).—Features of the fungus mycelium and its distribution in the affected rice culm are considered.

Sweet potato pox, R. H. DAINES (*New Jersey Stat. Cir.* 438 (1942), pp. 2).—An informative leaflet.

[Tobacco disease studies and observations at the Tobacco Substation], P. J. ANDERSON (*Connecticut [New Haven] Sta. Bul.* 457 (1942), pp. 248-260, figs. 2).—A brief report of progress is given on downy mildew control, including data on removal of paradichlorobenzene crystals and trials of liquid sprays; delayed frost injury to transplants in June; and a general account on tobacco mosaic (symptoms, extent of damage, the causal virus, spread and overwintering, and control, including resistant varieties).

Study of respiration in healthy and mosaic-infected tobacco plants, V. F. C. GLASSTONE (*Plant Physiol.*, 17 (1942), No. 2, pp. 267-277, figs. 5).—Using the same plants throughout each experiment, with apparatus and methods described, it was found that the respiratory ratio of infected and healthy plants remained at the same level until the disease became systemic. When vein clearing was apparent the respiratory rate of the affected plants rose rapidly, followed by a decrease until in the older plants it became approximately equal to that of the normals by the time mosaic mottling had developed. The percentage increase in respiratory rate was about 50 percent higher than in the corresponding healthy plants. There are 21 references.

An analysis of tobacco mosaic virus for biotin, riboflavin, and pantothenic acid, H. SPRINCE and E. B. SCHOENBACH (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 3, pp. 415-418).—The authors were unable by methods described to demonstrate the presence of these vitamins in significant amounts in moderately concentrated solutions of purified tobacco mosaic virus.

Liquid crystals of the virus of the tobacco mosaic (*Nicotiana virus 1* Allard), V. L. RISHKOV and V. A. SMIRNOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S.*, n. ser., 31 (1941), No. 9, pp. 930-932, figs. 2).—The method and various stages and influences in the development of these crystals, briefly outlined, are said to throw some light on the mechanism of crystalline virus accumulations in diseased cells. An essential role in their genesis is played by the protoplasmic currents, which favor a more regular orientation of virus particles and draw them closer together. The liquid crystals of the virus nucleoproteins, the mesomorphic fibrils formed by these proteins, and the chains of spindle-shaped paracrystals are all similar in chemical composition, as well as in physical and morphological characters, to some essential structural elements of protoplasm. It is therefore deemed likely that they may prove good models for studying the conditions under which paracrystalline structures of the protoplasm are formed.

Specific biological activity of tobacco-mosaic virus as influenced by age of lesion and nitrogen supply, E. L. SPENCER (*Plant Physiol.*, 17 (1942), No. 2, pp. 210-222, figs. 2).—Turkish tobacco plants grown in nutrient sand cultures and about 6 in. tall were inoculated on one of the lower mature leaves, and at intervals the virus was isolated by ultracentrifuge and assayed for biological activity. In the inoculated leaf the virus continued to increase both in amount and in specific biological activity per unit of weight for as long as 20 days after inoculation. Withdrawal of the N supply inhibited the increase in specific activity earlier than it did the increase in virus protein. Confirmation of the finding that virus in young lesions displays only a fraction of its potential biological activity was obtained by comparing virus isolated from the inoculated leaf with that from the more recently invaded top of the plant. Calculations from the rates of sedimentation in the analytical ultracentrifuge indicated that virus preparations from young lesions may contain particles considerably larger than those characteristic of preparations from older lesions. There are 13 references.

The effect of pH on inactivation of tobacco mosaic virus by X-rays, A. MARSHAK and W. N. TAKAHASHI. (Univ. Calif.). (*Natl. Acad. Sci. Proc.*, 28 (1942), No. 5, pp. 211-216, fig. 1).—It is concluded from this study that energy released by an ion pair produced within a virus particle may travel through that particle and inactivate one or more of the elementary virus units contained therein. Electrons reaching the virus from the suspending medium have sufficient energy to inactivate the virus particle. More of the electrons produced by X-rays in the suspending medium reach the virus particles when the particles carry a net positive charge than when it is negative, and the greater the net positive charge the more electrons will be attracted.

The broad ring-spot virus, J. JOHNSON and R. W. FULTON. (Wis. Expt. Sta. and U. S. D. A.). (*Phytopathology*, 32 (1942), No. 7, pp. 605-612, figs. 2).—A new virus found on tobacco in the field is described and given the common name "broad ring-spot" to distinguish it from other viruses inducing similar types of symptoms. It is transmissible to several other plant families, and its thermal death point is 54° C., maximum longevity in vitro about 42 hr., and dilution end point slightly above 1 in 1,000. It was apparently not filterable by ordinary methods, and was not transmitted by the common peach aphid (*Myzus persicae*). The properties and other characteristics are sufficient to distinguish this virus from certain others with which it was compared. Although too rare to be of practical significance, it is of some special interest to those working on problems relating to the origin and distribution of viruses in nature.

Changes in the metabolism of wheat leaves induced by infection with powdery mildew, P. J. ALLEN. (Univ. Calif.). (*Amer. Jour. Bot.*, 29 (1942), No. 6, pp. 425-435, figs. 20).—In lightly infected leaves the respiration curve was found to exhibit two maxima corresponding, respectively, to the time of maturity of the primary and of the secondary colonies. The maximum in winter-grown greenhouse plants was only about one-third that of plants grown under better lighting. Growth of a mildew colony is rapid during the period of increasing respiration, sugar, and starch, but after these reach their peak it slows down. Individual colonies on heavily infected plants, where the respiratory maximum occurs a week after inoculation, are therefore smaller than those on lightly infected ones, where respiration is not at its height for about 2 weeks. The substrate oxidized in lightly infected leaves is mainly carbohydrate, and also in the heavily infected ones up to the respiratory maximum, but thereafter other substances are also oxidized. Mildew infection leads to a break-down of the photosynthetic mechanism which involves both the light and dark reactions, and details are discussed. In heavily infected plants there is an accumulation of

soluble sugars reaching a maximum simultaneously with respiration. In infected leaves starch is deposited near the mildew colonies, being most abundant at the maxima of respiration and soluble sugars and disappearing as they decrease. During the early growth of the fungus chlorotic spots appear beneath each colony and spread outward until they fuse. Before the fusion is completed and at about the time of the respiratory maximum, chlorophyll is re-formed under the center of each colony and spreads outward to form green islands, each of which is about the size of a mildew colony. An estimate of the excess of carbohydrate produced over the amount utilized by the leaf showed that the quantity available for export decreases to zero or below at the time of the respiratory maximum, and thereafter all that is synthesized is utilized by the leaf itself. There are 27 references.

Controlling plant diseases in the home garden, C. M. TUCKER (*Missouri Sta. Cir.* 238 (1942), pp. 8).—An informative leaflet.

Vegetable disease problems on Long Island, H. S. CUNNINGHAM (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, pp. 14, 15, figs. 2).—This is a general discussion of the relations of climate, soil conditions, and intensive production to the incidence and effects of diseases, with particular reference to potatoes, crucifers, and sweet corn.

Bacterial blight of beans, C. M. HAENSELER (*New Jersey Stas. Cir.* 432 (1942), pp. 2).—An informative leaflet.

Club root of cabbage and related plants, C. M. HAENSELER (*New Jersey Stas. Cir.* 430 (1942), pp. 2).—An informative leaflet.

Sweet corn wilt and smut tests, 1941, C. M. HAENSELER (*New Jersey Stas. Plant Disease Notes*, 19 (1942), No. 12, pp. 45-47+[2]).—The reaction of 54 different lots of yellow sweet corn (about 100 stalks to the lot) as tested in the plant pathology plot are discussed and tabulated.

Finds five fungi chiefly to blame for pea root-rot, O. A. REINKING (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, p. 13).—Field surveys and laboratory tests have thrown light on the distribution and relative importance of the organisms causing this trouble. In this preliminary note a few practical points of general interest to pea growers are briefly presented, with emphasis on the value of crop rotation, proper fertilization, and seed treatment.

El matizado del pimienta en Puerto Rico [Mosaic of pimienta in Puerto Rico], J. ADSUAR (*Agr. Expt. [Puerto Rico Univ. Sta.]*, 2 (1942), No. 2, pp. 7-8, fig. 1).—This note concerns a mosaic-type virus disease of pimienta pepper on the Island and its control by resistant varieties.

Fusarium wilt of tomato, C. M. HAENSELER (*New Jersey Stas. Cir.* 431 (1942), pp. 2).—An informative leaflet.

Stickers and spreaders in orchard sprays, G. L. MACK and J. M. HAMILTON (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, p. 2, fig. 1).—With the recommended reductions in the amount of spray mixtures in order to conserve scarce materials, better coverage is a prime requisite. Stickers and spreaders are important in attaining this end, and this note evaluates their role and discusses their use.

How shall we spray and control pin point scab, D. CATION (*Mich. State Hort. Soc. Ann. Rpt.*, 70 (1940), pp. 84-88).—An address summarizing experimental data on the factors influencing such late apple scab infections and the best spray procedures for preventing it.

Arsenical injury and its control, E. J. RASMUSSEN (*Mich. State Hort. Soc. Ann. Rpt.*, 70 (1940), pp. 22-25).—The author briefly discusses the symptoms and factors influencing arsenical injury to apples and the experimental results of 1940 in Michigan, from which it was found that premature defoliation through use of lead arsenate on susceptible varieties could be almost entirely

prevented by adding a 1-4-100 or 2-4-100 ZnSO₄ lime mixture to all applications made 2 weeks after the calyx spray. Among the detailed recommendations, avoidance of indiscriminate use of lead arsenate is suggested.

Brown-rot control on peaches and other stone fruits, D. CATION (*Mich. State Hort. Soc. Ann. Rpt.*, 70 (1940), pp. 103-104).—Brief recommendations based on 1940 experiments.

Apothecia of *Sclerotinia fruticicola* on peach in western Washington, G. A. HUBER and K. BAUR. (West. Wash. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 7, pp. 635-636, fig. 1).—The apothecia were found developing from peach mummies in Washington during the spring of 1941. This is believed to be the first report for the State.

Peach yellows and little peach, T. F. MANNS (*Delaware Sta. Bul.* 236 (1942), pp. 50, figs. 15).—The author briefly outlines the investigations and status of these two diseases prior to 1915 and summarizes his own studies beginning in 1915 and extending through 1941, with 33 references to the more recent literature. Both virus diseases are spread by the plum leafhopper (*Macropsis trimaculata*), which breeds abundantly in Delaware on all plum varieties, both wild and cultivated, and also on neglected peach and apricot, but has not been found on cherries. Some plum varieties mask these diseases, the Myrobalan plum (*Prunus cerasifera*), chief foundation rootstock for budding to cultivated plums, being one of these symptomless carriers. Certain oriental plums (*P. salicina*) may carry these diseases and live for years. They are also hosts of large numbers of plum leafhoppers, one such tree carrying over 12,000 vectors. In well-sprayed peach orchards this insect was difficult to find. In the station variety plum orchard, 19 of 52 plums 28 yr. old, when budded onto peach, were shown to be little peach carriers and 9 were carrying yellows. Epidemics of both diseases on the station farm have been related to the variety plum orchard. Control in commercial peach orchards involves removal of all plums within about a mile, as well as all infected peach trees. The facts established by this series of researches are briefly summarized, and an appendix characterizes 9 virus diseases of peaches.

Banded chlorosis, a transmissible disease of cherry, S. M. ZELLER and J. A. MILBETH. (Oreg. Expt. Sta.). (*Phytopathology*, 32 (1942), No. 7, pp. 634-635, fig. 1).—The new virus disease described from Japanese flowering cherry (*Prunus serrulata*) proved transmissible by budding whether or not the buds "took." It was transmitted also to mazzard stock. The virus is named *Marmor pallidolimbatus* and *Prunus virus 10*.

Trade role in control of cherry yellows, E. M. HILDEBRAND. (Cornell Univ.). (*Amer. Nurseryman*, 75 (1942), No. 8, pp. 9-10).

Failure to inactivate the false blossom virus in dormant cranberry vines by heat, N. E. STEVENS (*Cranberries*, 7 (1942), No. 1, p. 8).—In the tests reported, temperatures high enough to inactivate the virus killed or hopelessly stunted the plants. No difference was noted in the heat resistance of dormant, healthy, and diseased vines.

Strawberry leaf roll, a new disease, G. H. BECKLEY and A. G. PLAKIDAS. (La. Expt. Sta. et al.). (*Phytopathology*, 32 (1942), No. 7, pp. 631-633, fig. 1).—An apparently new strawberry disease found in Canada and New York State is described and named "strawberry leaf roll," pronounced downward rolling of the leaflets being its most characteristic symptom. Its transmission by runner grafting seems to indicate its virus nature.

Mould control in grapes: Results obtained with the use of sulphur dioxide, I. DONEN (*Farming in So. Africa*, 17 (1942), No. 192, pp. 199-208, figs. 3).—Testing about 500 boxes of grapes, of which 300 were treated with SO₂, the results

are said to indicate the gas treatment a very promising method of increasing the selling life of nonrefrigerated fruit sent to African markets.

Olive anthracnose in the United States, R. E. PONTIS and H. N. HANSEN. (Univ. Calif. et al.). (*Phytopathology*, 32 (1942), No. 7, pp. 642-644, fig. 1).—This disease was found on Mission variety fruits in December 1941 at Berkeley, Calif. *Gloeosporium olivarum* was identified as the cause, inoculations producing symptoms after 36 hr. This is said to be the first report of the fungus for the United States.

Swollen shoot and die-back of cacao, O. J. VOELCKER and J. WEST (*Trop. Agr. [Trinidad]*, 19 (1942), No. 5, p. 83).—The chief characteristics distinguishing this disease from ordinary forms of dieback are emphasized.

Prevention of brown rot, H. S. FAWCETT and L. J. KLOTZ. (Calif. Citrus Expt. Sta.). (*Calif. Citrog.*, 27 (1942), No. 6, p. 156).—Proper planting and fungicidal procedures as aids in avoiding a large amount of brown rot gummosis are summarized.

Gegevens, verkregen bij het onderzoek naar de waardplanten van *Tylenchus coffeae* [Investigation of the host plants of *T. coffeae*], H. J. DE FLUITER and J. J. MULHOLLAND (*Bergcultures*, 15 (1941), No. 47, pp. 1588-1593).

Duration of effect [of] zinc sulphate treatments on large, badly rosetted pecan trees, A. C. GOSSARD and H. E. PARSON. (U. S. D. A.). (*Peanut Jour. and Nut World*, 20 (1941), No. 9, pp. 13-14, 25).—This is a summary of trials with soil application and injection of ZnSO₄ for controlling rosette in mature pecan trees, begun in 1933-34 but without further treatments, and with records kept through 1940. Differences between treated and control trees, in favor of the former, were greatest in 1935-36, and the general indication was that the corrective effect of Zn tended to decrease slightly after 4-5 yr.

Pythium disease of fibrous-rooted begonia and its control, J. T. MIDDLETON, C. M. TUCKER, and C. M. TOMPKINS. (Calif. and Mo. Expt. Stas. et al.). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 2, pp. 89-95, figs. 2).—The authors describe a destructive crown and stem disease of *Begonia semperflorens*, prevalent in California and Missouri. The symptoms consist of a watery rotting of crown, stem, petiole, and leaf tissues. When stems become infected several inches above the soil line the plants eventually collapse. The roots are usually not attacked. In California the disease is caused by *Pythium ultimum* and in Missouri by *P. debaryanum*, *P. splendens*, and *P. ultimum*, all proving pathogenic on inoculation. The cardinal temperature points of the fungi are for *P. debaryanum* 4°, 28°-31°, and 37° C.; for *P. splendens* 10°, 28°-31°, and 34°; and for *P. ultimum* 4°, 25°-28°, and 37°. Overcrowding, excessive watering, and relatively high temperatures are predisposing factors. The disease may be controlled in the greenhouse by using steam-sterilized flats and soil. For outdoor plantings an immune variety is available.

Stem canker of camellia, B. H. DAVIS and P. P. PIBONE (*New Jersey Stas. Nursery Disease Notes*, 14 (1942), No. 9, pp. 32-35).—The symptoms of a stem canker under study for the past 2 yr. and found due to *Glomerella cingulata* are described. In cross-inoculations, isolates from camellia and apple failed to infect twigs of the reverse hosts, but apple fruits and camellia leaves were attacked. General suggestions as to control are given.

Verticillium wilt of chrysanthemums and its control, P. E. TILFORD and H. A. RUNNELS (*Ohio Sta. Bul.* 630 (1942), pp. [1]+23, figs. 5).—This serious and widespread disease occurs to some extent in most greenhouses where chrysanthemums are grown, and many otherwise excellent varieties have been discarded by florists because of susceptibility. Distinct wilting occurs in some varieties, whereas in others no wilting is evident. Affected plants are stunted

and their leaves die from the base up the stem. The symptoms become increasingly severe and are most evident during blooming, but the plants are seldom killed. As it occurs in Ohio, the disease is due to *V. dahliae*, a common soil fungus infecting many plant species. It enters chrysanthemum plants through the roots, invading the xylem of roots, stems, and leaves. It is disseminated by infested soil and by cuttings from diseased plants. Control is effected by soil sterilization and use of cuttings from healthy plants. Plants for propagation should be selected in the fall before the blooms are cut, forced into rapid growth in late winter and spring, and tip cuttings made from the most vigorous shoots. Only resistant varieties should be grown unless the soil can be sterilized. Steam sterilization of the soil is said to be more satisfactory than by formaldehyde or chloropicrin, but where not feasible the chemical methods may be used.

Control of Fusarium yellows of gladiolus by resistance, R. NELSON. (Mich. Expt. Sta.). (*Gladiolus Sup.* [New England Gladiolus Soc.], 6 (1942), No. 2, pp. 4-9).—This is a brief summary of work by the station (1935-41) in controlling this important gladiolus disease, with lists of susceptible and resistant varieties.

Stem and stolon canker of Pachysandra, P. P. PIBONE (*New Jersey Stas. Nursery Disease Notes*, 14 (1942), No. 11, pp. 40-43).—Proof is presented of the pathogenicity of a large-spored species of *Volutella* in causing stem and stolon canker, said to be the most destructive fungus infection of *P. terminalis*. The history and symptoms of the disease are given, and control suggestions are made.

Bud blast of peony, P. P. PIBONE and O. W. DAVIDSON (*New Jersey Stas. Nursery Disease Notes*, 14 (1942), No. 12, pp. 44-47).—Observations and isolation trials have reopened the question as to the cause of the bud blast of peony hitherto ascribed to *Botrytis* spp., and the possibility of other factors (nematodes, weather, nutrition) being involved in cases showing symptoms atypical of *Botrytis* infection is suggested.

The snapdragon rust, W. C. BLASDALE (*Jour. Calif. Hort. Soc.*, 3 (1942), No. 3, pp. 126-129).—A general discussion of this rust disease, its history, cause (*Puccinia antirrhini*), hosts, and control by the development of resistant varieties, particularly through work by the California Experiment Station and seed growers of the State.

The production of sporidia of Cronartium ribicola on cultivated red currants in relation to infection of white pine, W. H. SNELL (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 506-513).—From a considerable body of data on number of leaves, total leaf area, and numbers of telia and sporidia per bush for cultivated red and European black currants and for wild gooseberries, it is shown that a garden row of red currants will produce only a fraction of the number produced by black currants. Several factors in reducing the total sporidium production on red currants are discussed, viz, the smaller number of bushes in a row or patch that become infected, the high resistance of mature leaves, the tendency to produce a single set of leaves per season, lower viability of teliospores and sporidia, early defoliation, necrosis of blister rust spots, and reduced size of telia. By use of the "threshold" or "quantum" principle, which derives a certain theoretical volume of sporidia for producing a single canker on pine, it is shown that maximum sporidium production of red currants in New York is at least very close to, if it may not be far below, the lowest limits necessary to infect pine, especially for severe infection, unless possibly under unusually favorable circumstances. This study is believed to indicate definitely that red currants cannot be considered very dangerous to white pine, if at all so, and that the necessity of applying the 900-ft. eradica-

tion zone to them in gardens should be conclusively demonstrated. There are 21 references.

Hormodendrum resinae (Lindau), an inhabitant of wood impregnated with creosote and coal tar, C. M. CHRISTENSEN, F. H. KAUFERT, H. SCHMITZ, and J. L. ALLISON. (Minn. Expt. Sta.). (*Amer. Jour. Bot.*, 29 (1942), No. 7, pp. 552-558, figs. 2).—A fungus tentatively identified as *H. resinae* was isolated from various creosoted wood products collected over a wide area of the United States, and it appears to be a universal inhabitant of creosote and coal tar treated wood in service. It is deemed not unlikely that this fungus is a common saprophyte in soil, untreated wood, or plant refuse, since it was unable to survive well in competition with common molds. Resinous bark and wood possibly formed the original source of inoculum, though other sources may exist. *H. resinae* not only tolerates a far higher concentration of creosote and coal tar than other known fungi but can grow and reproduce with no other source of nutriment, apparently being able to metabolize some of the components of these materials. The fungus proved no more resistant to inorganic toxicants than a number of other fungi. It appears to have no effect on the strength of the wood it infects. An unidentified bacterium was also isolated from a large majority of the creosoted wood samples investigated.

The transient feeding of root-knot nematode larvae, M. B. LINFORD. (Univ. Hawaii.) (*Phytopathology*, 32 (1942), No. 7, pp. 580-589, figs. 3).—*Heterodera marioni* larvae begin feeding on the root surface and continue as they enter into and migrate within the root. They insert the tip of the stylet into a cell with some difficulty, lie at rest a few seconds, then suck out part of the cell substance without killing the cell. A few cells at the point of entry and occasionally elsewhere are disrupted by the migrating nematodes. Larvae attacking in groups destroy many cells, causing holes, cracks, or (in extremely heavy infestation) disintegration of the root tips. This feeding during entry and migration apparently explains the prompt interruption of root elongation, the swelling of root tips, and the early hypertrophy of some cells remote from the site of permanent feeding.

Chloropicrin and ethylene dichloride for root-knot nematode control, A. G. NEWHALL and F. L. STARK, JR. (Cornell Univ.) (*Phytopathology*, 32 (1942), No. 7, pp. 626-630, figs. 2).—The effectiveness of chloropicrin and ethylene dichloride, separately or in mixture, as soil fumigants for controlling *Heterodera marioni* was compared, and a simple statistical method (described) of evaluating volatile soil fumigants was used. Excellent control in a greenhouse sandy soil was obtained on a spring tomato crop by soil treatments the previous September, using (1) chloropicrin at 10.5 lb. per 1,000 sq. ft. (460 lb. per acre) applied at 10-in. intervals, at 2 cc. per injection, 4-5 in. deep, and (2) a mixture of chloropicrin and ethylene dichloride, 1-9, at 10 cc. per injection (230 lb. chloropicrin plus 1,594 lb. ethylene dichloride per acre). Less effective control was obtained by 15 cc. injections of straight ethylene dichloride, 2,656 lb. per acre. At the advanced 1941 price of 12 ct. per pound this is not recommended either alone or in mixture, but at sufficiently lower prices its use as a substitute for half of the chloropicrin may be considered as an economy measure.

ECONOMIC ZOOLOGY—ENTOMOLOGY

[Investigations in economic zoology and entomology by the Arizona Station] (*Arizona Sta. Rpt. 1941*, pp. 45-46, 54-56).—A progress report (E. S. R., 85, p. 641) noting research on forage requirements of range vegetation by jack rabbits, scale insects, and the biology and control of the cotton pest *Oreontiades femoralis* Van D.

[Investigations in economic zoology and entomology by the Massachusetts Station] (*Massachusetts Sta. Bul.* 388 (1942), pp. 37-38, 50-52, 54-55, 57-66, 74, figs. 3).—A progress report (E. S. R., 85, p. 786) by H. J. Franklin, A. I. Bourne, W. D. Whitcomb, W. Garland, W. E. Tomlinson, Jr., W. B. Becker, A. S. Levine, C. R. Fellers, and J. Lubitz which notes as insects affecting the cranberry, the hill fireworm *Thiascula finitella* Walk. and the cranberry root grub *Amphitoma vulpina*, the control of the cranberry fruitworm, gypsy moth, cranberry girdler, and black-headed fireworm, and the prevalence of cranberry pests; oil sprays for dormant applications and summer treatments for control of European red mite; control of the cabbage maggot, squash vine borer, and onion thrips; the spray residue problem; apple maggot control; insecticides for control of the European corn borer; potato spraying experiments; introduction of parasites of oriental fruit moth in peach orchards; naphthalene and similar compounds as greenhouse fumigants; control of the common red spider on greenhouse plants; biology and control of the apple leaf curling midge; control of plum curculio in apples; biology and control of the grape plume moth and grape cane girdler; insects and Dutch elm disease; and red squill research.

Rodent pests of Iowa and their control, H. GUNDERSON and G. C. DECKER (*Iowa Sta. Bul.* P43, n. ser. (1942), pp. 421-436, figs. 8).—A practical account of the important rodent forms met with in the State and means for their control.

Uses and management of ponds and lakes, H. S. TELFORD and O. A. STEVENS (*North Dakota Sta. Bul.* 313 (1942), pp. 40, figs. 15).—Following a brief foreword by H. L. Walster, the director, part 1 of this bulletin (pp. 3-14) deals with the value of ponds to the farm and community, including particularly their many uses, i. e., for livestock, fish, waterfowl, songbirds, muskrats, and recreation; and part 2 (pp. 14-34) presents the results of a survey of 19 lakes and ponds in the State, including their chemical and physical properties and the beneficial and injurious occupants. A list of selected references to the literature and tables reporting the physical and chemical properties of the water and the kinds and abundance of species are included.

The grey field slug *Agriolimax agrestis* L. and its environment, R. CARRICK (*Ann. Appl. Biol.*, 29 (1942), No. 1, pp. 43-55, figs. 4).—A study of the physical environment of *A. agrestis* in the laboratory is reported upon, the results having been correlated with conditions in the field with particular reference to the occurrence of outbreaks on the potato crop in the Lothians of Scotland. "The slug tolerates a wide range of soil pH. Soils of high water-holding capacity sustain the densest populations of slugs, and they must be 40-80 percent saturated before oviposition followed by development of the eggs can occur. The maximum lethal temperature is about 35° C. The zone of effective temperatures extends from just above freezing point to 25°, and there is a high degree of resistance to freezing. Oviposition occurs anywhere between 3° and 20°. Time of development of the egg varies from 105 days at 5° to 18 days at 20° and mortality of the egg increases from 0 at 5° to 37 percent at 20°. Hatching of the egg is inhibited below 5°. Temperature exercises a direct controlling effect on development. Normal extremes of weather in Britain are not usually lethal to *A. agrestis*, but they do serve to inhibit adult activity and reproduction. In winter, manuring of the fields tends to counteract the lethal effect of adverse weather, and rainfall in late summer is important in determining the extent of damage by slugs to potato tubers during autumn."

Baiting slugs using metaldehyde mixed with various substances, H. F. JARNES and J. W. WEIL (*Ann. Appl. Biol.*, 29 (1942), No. 1, pp. 56-68, figs. 6).—Following a brief review of the literature concerning mixtures of other substances

with metaldehyde for use as slug baits, an account is given of the comparison of the numbers caught by 44 substances and by bran in metaldehyde baits. It is shown that baits containing feeding stuffs are undoubtedly better than baits of metaldehyde alone or metaldehyde mixed with nonfeeding stuffs, such as soil, sand, etc. Nutritive feeding stuffs, such as cakes and meals, are better as a group than roughage feeding stuffs, such as bran. The efficiency of metaldehyde baits is discussed. The range of effectiveness of the baits, the proportion of slugs visiting the baits dying, the speed of annihilating a slug population, the most economical strength of metaldehyde to use, as well as the mixing of the baits and their distribution are points which need further investigation. Meanwhile, it is suggested that it is worth while using small quantities of a feeding stuff in order to save much larger quantities of crops which are themselves feeding stuffs. A large slug population can be greatly reduced by a single application of metaldehyde plus a feeding stuff and can be subsequently prevented by the use of metaldehyde and an inert or nonfeeding stuff diluent from reaching undue proportions again.

The maintenance of high atmospheric humidities for entomological work with glycerol-water mixtures, C. G. JOHNSON (*Ann. Appl. Biol.*, 27 (1940), No. 2, pp. 295-299, figs. 2).

The relation of unfreezable water to cold-hardiness of insects, L. P. DITTMAN, G. B. VOET, and D. R. SMITH. (Md. Expt. Sta.) (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 265-272, figs. 7).—Determinations made of unfreezable water at various subzero temperatures from above to below the undercooling range in overwintering European corn borer, codling moth, southern cornstalk borer, corn earworm, and squash bug and on summer forms of European corn borer, corn earworm, squash bug, and Mexican bean beetle have shown maximum freezing to take place as soon as the undercooling points were reached. When insect samples were frozen to temperatures below their undercooling range there was remarkable uniformity in the percentage of unfreezable water in all species studied, and complete freezing of body water did not occur at temperatures as low as -40° C. (-40° F.). There was no relation of either the percentage of total water unfreezable or the unfreezable water-dry weight ratio to cold hardiness when the insects were frozen below the undercooling temperature.

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 264, 281-291, figs. 3).—Contributions presented (E. S. R., 87, p. 247) are: The Effect of Parasites and Predators on Corn Earworms in Sumac Sogro Heads, by J. R. Quinby and J. C. Gaines (p. 284) (Tex. Expt. Sta.); Woolly Apple Aphid Infesting Apple Cores, by E. O. Essig (p. 281), and A Convenient Cage for Confining Insects to Plants, by J. T. Medler (pp. 283-284) (both Univ. Calif.); Thiocyanate-Derris Dusts for Control of Truck Crop Insects, by H. G. Walker and L. D. Anderson (pp. 281-282) (Va. Truck Sta.); A Simple Method of Obtaining Standardized Houseflies, by P. De Bach (pp. 282-283), and The Deposition of Non-viable Eggs by Hymenoptera (p. 283) and The Introduction of *Physcus testaceus* Masi Into California (pp. 290-291), both by S. E. Flanders (all Calif. Citrus Sta.); Field Studies of Codling Moth Larvae Attractants, by C. W. Wingo and H. E. Brown (pp. 284-285) (Univ. Mo.); Insecticides Derived From Plants, by N. E. McIndoo (pp. 285-286), Effect of Bentonite and of Hydrated Lime on the Toxicity of Phenothiazine to Codling Moth Larvae, by E. H. Siegler and L. E. Smith (pp. 286-287), What is London Purple? by R. C. Roark (pp. 287-288), and A Pyrethrum-Sesame Oil Aerosol Used Against Cheese Skipper Adults, by S. C. Billings, L. D. Goodhue, and W. N. Sullivan (pp. 289-290) (all U. S. D. A.); A Method of Locating Insect Eggs in Plant Tissues, by W. E. Curtis (p. 286) (Cornell Univ.); Two Species of Black Carpet Beetle, by W. and M. B. Moore (p.

288); Volatile Fluorine Compounds for the Control of Insects, by S. Marcovitch (pp. 288-289) (Univ. Tenn.); A Destructive European Insect [*Amphimallus majalis* Razoum (*rufescens* Latr.)] New to the United States, by F. L. Gambrell, S. C. Mendall, and E. H. Smith (p. 289) (N. Y. State Sta.); and The Oviposition Habits of *Feltia subgothica* Haworth, by W. V. Balduf (p. 290) (Univ. Ill.).

[Insect investigations by the New Haven Station]. (Partly coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul.* 452 (1942), pp. 9-12, 12-13).—A progress report (E. S. R., 86, p. 65) noting studies by R. B. Friend et al. on the European corn borer, squash vine borer, oriental fruit moth, European red mite, insecticides for orchard use, Japanese beetle, gypsy moth, European pine shoot moth, white pine weevil, grassland insect investigations, and settling rates of diluents in dusts.

Insect investigations during 1941, A. W. MORRILL, JR., and D. S. LACROIX. (Coop. U. S. D. A.). (*Connecticut [New Haven] Sta. Bul.* 457 (1942), pp. 260-266, fig. 1).—A progress report (E. S. R., 85, p. 786) noting work with the potato flea beetle, tobacco thrips, and wireworm control, as well as mention of the more abundant insects during 1941.

[Entomological studies by the Florida Station] (*Florida Sta. Rpt.* 1941, pp. 71, 72-75, 149-153, 161-162, 165-166, fig. 1).—Progress (E. S. R., 85, p. 641) at the main station discussed included work with the Florida flower thrips, introduction and propagation of beneficial insects, onion thrips, and the pepper weevil, all by J. R. Watson; the larger plant bugs, by H. E. Bratley; control of fruit and nut crop insects, by Watson, S. O. Hill, and Bratley; the gladiolus thrips, by Watson and J. W. Wilson; biology and control of Florida aphids, by A. N. Tissot; and life history, food preferences, ecological distribution, and control of the eastern lubber grasshopper, by Watson and Bratley. Work at the Citrus Substation included control of the purple scale and the combined control of scale insects and mites on citrus, both by W. L. Thompson, and at the Everglades Substation research with wireworms, the bean leafhopper, bean leaf roller, and the prevalence and control of the sugarcane borer, all by Wilson.

[Entomological investigations by the Kentucky Station] (*Kentucky Sta. Rpt.* 1941, pp. 18-19, 25-26, 30, 32-35).—A progress report (E. S. R., 85, p. 786) noting the effect of the meadow plant bug on bluegrass seed setting; control of poultry lice, corn earworm, fruitworm, green June beetle grubs in bluegrass and in tobacco beds, and of white grubs in bluegrass sod; tests of oil-nicotine spray for insects; May beetle control; and methyl bromide fumigation for control of the strawberry crown borer.

[Entomological investigations by the Wyoming Station]. (Coop. U. S. D. A.). (*Wyoming Sta. Rpt.* 1941, pp. 13-16).—A progress report (E. S. R., 85, p. 91) noting work by Pfadt, [C. H.] Gilbert, and A. P. Sturtevant on range grasshoppers and on bee culture, including resistance of bees to disease.

Entomological investigations (*Austral. Council Sci. and Indus. Res. Ann. Rpt.*, 15 (1940-41), pp. 17-27).—Investigational work of the year with insects of importance, particularly as crop pests, their occurrence and control, is reported.

Cotton insect investigations in Peru, F. F. BIBBY (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 193-197, figs. 3).—A study of cotton insects made in Peru from September 1938 to March 1939, inclusive, primarily of the control of the cotton aphid and of thrips, largely *Leucothrips piercei* Morg., which are serious pests of cotton in that country, is reported upon.

Some natural enemies of stored-tobacco insects, with biological notes, C. O. BARE. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 185-189).—In the course of collections and observations on the biology, made during the fall of 1939 and in 1940, of the enemies of the cigarette beetle and the tobacco moth in tobacco warehouses of Virginia and North Carolina, 3 species of para-

sites and 3 predators of the cigarette beetle and 3 parasites and 11 predators of the tobacco moth were found. The most important parasites were *Aplastomorpha calandreae* (How.) on cigarette beetle larvae and pupae and *Microbracon hebetor* (Say) on tobacco moth larvae. The predators, with the possible exception of the mites, were of only incidental importance. *Monieziella* mites on the cigarette beetle and *Seiulus* and *Cheyletus* mites on the tobacco moth were important natural enemies. None of the species was observed to bring about a large degree of reduction in the numbers of their hosts.

Control of insects attacking stored tobacco and tobacco products, W. D. REED and J. P. VINZANT (*U. S. Dept. Agr. Cir. 635* (1942), pp. 40, figs. 23).—The tobacco industry suffers heavy losses from infestations of the tobacco moth and the cigarette beetle. The cigarette beetle is cosmopolitan in distribution and a destructive pest of cured and manufactured tobacco throughout the world. In Virginia and North Carolina the overwintered larvae start pupating in April, and the spring brood of beetles start emergence about May 15. Most individuals of a generation complete development in from 50 to 60 days, although there is an overlapping of generations. In southern climates and heated factories breeding may be continuous throughout the year. The tobacco moth was first recorded as a pest of stored tobacco in Europe in 1909, and infestations are largely confined to flue-cured and imported types of cigarette tobacco. Winter is passed in the larval stage and pupation begins in March. During warm weather the egg-to-adult period of moths is about 60 days. Infestations originate on the farm before tobacco is sold or in the storage or factory after the tobacco is redried and packed. Control of the insects in open-type warehouses consists of the use of insect traps, weekly applications of pyrethrum powder, and screening of warehouses. In closed-type warehouses control may be effected by periodic fumigations with hydrocyanic acid at dosages of 10 and 16 oz. per 1,000 cu. ft. with an exposure of 72 hr. Control in chamber fumigations at atmospheric pressure and reduced pressures includes the use of liquid hydrocyanic acid, sodium cyanide and sulfuric acid, calcium cyanide, carbon disulfide, a mixture of ethylene oxide and carbon dioxide, and a mixture of methyl formate and carbon dioxide.

A list of unimportant species of insects found in stored tobacco and the parasites of the tobacco moth and cigarette beetle is given. A program of insect control for the industry is discussed, figures on the cost are given, and safeguards to be employed in handling the fumigants are emphasized.

Fumigation of open-type tobacco warehouses, J. N. TENHET and W. D. REED. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 190–193, figs. 3).—Progress has recently been made in the fumigation of tobacco stored in the open-type tobacco warehouses through the use of rubberized canvas curtains to cover the open spaces along the walls. This material was practically gasproof, and the open warehouses were temporarily closed for effective fumigation. The curtains were each 77 by 12 ft. and two covered one outer wall. The total cost of each, including grommets, rings, and tie ropes, was \$55 and the cost per warehouse \$220. Mortality tests were made with lots of cigarette beetles and tobacco moths placed in the warehouses during the fumigation, and catches of insects were made in suction light traps. Dosages of 6 oz. and 12 oz. of hydrocyanic acid gas were applied with exposures of 48 and 50 hr. under conditions of summer temperatures. The most satisfactory results were obtained with a 12-oz. dosage and a 50-hr. exposure at 87° F. at the start of the fumigation.

Insects and other pests of Florida vegetables, J. R. WATSON and A. N. TISSOT (*Florida Sta. Bul. 370* (1942), pp. 118, figs. 63).—This is a revision and enlargement of Bulletin 232 (E. S. R., 66, p. 551).

Los insectos dañinos en las hortalizas [Insects destructive to vegetables], F. SKIN, JR. (*Agr. Hopt. (Puerto Rico Univ. Sta.)*, 2 (1942), No. 2, pp. 2-5, figs. 3).—A practical account.

Mushroom insects: Their biology and control, C. A. THOMAS (*Pennsylvania Sta. Bul.* 419 (1942), pp. [4]+43, figs. 43).—This publication includes descriptions, biologies, injuries, and control measures for fungus gnats (sciarids), manure flies (phorids), gall gnats (cecid flies), springtails, mushroom mites, and minor pests, including sowbugs, slugs, looper caterpillars, nematodes, rats and mice, wireworms, beetles, and chironomid flies. Control measures discussed are high temperatures—natural fermentation of manure, low temperatures, fumigation during heating of manure and during growth of crop, dusts and dusting, sprays, and light traps. An extensive bibliography is included.

[Contributions on fruit insects control] (*Mass. Fruit Growers' Assoc. Rpt.*, 47 (1941), pp. 20-22, 120-132).—Contributions presented at the 1941 meeting of the association include Orchard Insects in 1940, by W. D. Whitcomb and A. I. Bourne (pp. 20-22), Insect Pests of 1940 and What to Expect in 1941, by A. I. Bourne (pp. 120-126), and More Fruit Insects of 1940—and 1941? by W. D. Whitcomb (pp. 126-132) (all Mass. State Col.).

Insect and disease control of fruit plants, T. E. ASHLEY (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 7, pp. 5-6).—A practical account.

Developments with the control of fruit insects during the past 75 years, J. S. HOUSER. (Ohio Expt. Sta.). (*Ohio State Hort. Soc. Proc.*, 75 (1942), pp. 113-125).

[Contributions on fruit insects] (*Oreg. State Hort. Soc. Ann. Rpt.*, 32 (1940), pp. 57-71, figs. 3).—Contributions presented at the 1940 meeting of the society include Some Observations on Codling Moth Flight and Worm Entries, 1940, by C. B. Cordy (pp. 57-60); and Codling Moth Control on Pears, by L. G. Gentner (pp. 61-64), and Progress Report on the Pear Psylla Control Program in the Pacific Northwest, by L. Childs (pp. 65-69) (both Oreg. Expt. Sta.).

Common insect larvae that attack the apple in Pennsylvania, S. W. FROST (*Pennsylvania Sta. Bul.* 420 (1942), pp. [2]+30, figs. 20).—This publication includes keys for the identification of insects injurious to apples and a discussion of common larvae that attack apple in Pennsylvania. Selected references to larvae that attack apples are listed.

Parasites of the oriental fruit moth and of certain weed-infesting larvae, M. L. BOBB (*Virginia Sta. Tech. Bul.* 79 (1942), pp. 23, figs. 9).—During the 8-yr. period covered by this investigation 45 species of parasites were reared from larvae of the oriental fruit moth, the ragweed borer *Epiblema strenuana* Walk., and the bidens borer *E. otiosana* Clem. and 2 species from the pupae of the oriental fruit moth. *Macrocentrus ancylivorus* Roh. represented 83.30 percent. *Glypta rufiscutellaris* Cress. 8.56, and *M. delicatus* Cress. 5 percent of the parasites reared, and these species were taken in 10 of the 11 localities where twig collections were made. More females were reared than males. Data obtained indicate that larvae of the oriental fruit moth are parasitized when 1 week or less in age. *E. strenuana* was heavily parasitized during 1940 and 1941 in Albemarle County. Parasites destroyed from 85.55 to 94.11 percent of *E. otiosana* in Spanish-needles and beggarticks from 1939 to 1941 and 95.5 percent of this borer in cocklebur in 1939. A higher percentage of oriental fruit moth larvae was parasitized in the early season in weedy orchards.

Spraying for control of grapeberry moth and grape leafhopper, R. HUTSON (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 287-290, fig. 1).—As a result of experiments on the grapeberry moth during the last three growing seasons, the author concluded that (1) the use of arsenical sprays seems necessary, (2)

there is little difference in control until the number of arsenical sprays has been cut below three, and (3) fixed nicotine in the last two sprays will protect against both grapeberry moth and grape leafhopper.

Evaluating protection of fabrics from clothes moth and carpet beetle attack, R. E. HEAL. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 249-255).—Description is given of procedures for the maintenance of laboratory cultures of the webbing clothes moth, the black carpet beetle, and the furniture carpet beetle *Anthrenus vorax* Wtrh. on a known-age basis. A method is outlined for the evaluation of the protection of fabrics against attack by subjecting them to the feeding of larvae of the webbing clothes moth, black carpet beetle, and *A. vorax* under carefully controlled conditions. Data are presented to show that resistance of a fabric to the attack of the larvae of any single species does not assure that the fabric is effectively protected against the attack of other species.

The analysis of toxicity tests on mixtures of poisons, D. J. FINNEY (*Ann. Appl. Biol.*, 29 (1942), No. 1, pp. 82-94, fig. 1).

The examination of plants for insecticidal constituents, R. C. ROARK. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 273-275).

The insecticidal properties of certain species of *Annona* and of an Indian strain of *Mundulea sericea* ("Supli"), F. TATTERSFIELD and C. POTTER (*Ann. Appl. Biol.*, 27 (1940), No. 2, pp. 262-273, fig. 1).—It has been shown in preliminary laboratory insecticidal tests with several species of *Annona*, including *A. muricata*, *A. palustris*, *A. reticulata*, and *A. squamosa*, that plants of this genus possess contact insecticidal properties to aphids. *A. reticulata* was the most potent of those tested. Seed, root, leaf, and, to a less extent, the stems of this species possessed contact insecticidal properties. The seed of *A. muricata* and the leaves of *A. squamosa* and *A. palustris* also showed contact toxicity, but were not so potent as *A. reticulata*. The seed of *A. squamosa* was not available for testing purposes. None of the above are superior to the leaf, root, and bark of *M. sericea* of the variety known in India as Supli and are much less toxic than the richer specimens of *Derris elliptica* root such as Changi No. 3. The toxic action of the *Annona* spp. appears to be rather specific. Aphids are susceptible, but adult saw-toothed grain beetles, which are susceptible to the rotenone class of insecticides, are resistant. Tests made with extracts of a variety of *M. sericea* from India showed that leaf, bark, and root possessed marked insecticidal properties when tested on the chrysanthemum aphid and the saw-toothed grain beetle. This is in contrast with the African variety, the leaf and root of which are reported as distinctly less potent than the bark. The toxicity of none of these parts is of the same order as that of the root of *D. elliptica*, Changi No. 3.

Studies of nicotine as an insect fumigant, H. H. RICHARDSON and A. H. CASANGES. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 242-246, fig. 1).—Report is made of the results of laboratory work with nicotine vapor, using an air-flow apparatus, against 37 species of insects. The resistance to nicotine of the different insects varied widely. Thirteen species of aphids and thrips and 6 other species were killed by concentrations of 0.003 to 0.025 mg. per liter in 30-min. or shorter exposures at 25° C. (77° F.). The resistance of the green peach aphid varied greatly on three host plants. Nearly mature larvae of the southern armyworm and the corn earworm were much more resistant than young larvae, but there was little difference with the silkworm larvae. Comparative ratings of resistance made at 95-percent-kill concentration differed at times from those made at 50-percent-kill concentration. Because of its greater practical value the 95-percent rating seems preferable for use in making comparisons of resistance. Nicotine acts rapidly against some insects, giving complete

kill in a 1-min. fumigation. Short exposures to high concentrations were more effective than proportionately long exposures to low concentrations of gases. Gas concentration affected efficiency more than did exposure time. This relationship appeared fairly constant for each of the 4 insects tested over a limited range of exposures. Nicotine appeared much more toxic in the laboratory than hydrocyanic acid to several insects on the basis of a comparison with published results with the latter gas.

The effects of pyrethrins on certain mammals, C. S. LEONARD. (Univ. Vt.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 261-264).—Experimental inoculations of rodents, including mice, white rats, guinea pigs, and rabbits, to determine the effects of pyrethrins are reported.

The problem of the evaluation of rotenone-containing plants, V, VI, J. T. MARTIN (*Ann. Appl. Biol.*, 27 (1940), No. 2, pp. 274-294, fig. 1; 29 (1942), No. 1, pp. 69-81, figs. 2).—Two further contributions (E. S. R., 80, p. 369).

V. The relative toxicities of different species of *Derris* (pp. 274-294).—In this work the relative toxicities to the bean aphid of different species and varieties of derris root were determined. *D. elliptica* (Changi root) was 2.5 times, *D. malaccensis* (Sarawakensis root) 1.75 times, and *D. elliptica* (Sarawak creeping root) 1.25 times as toxic as *D. malaccensis* (Kinta root). Preliminary trials have shown the relative toxicities of three of the roots to a stored products insect, the saw-toothed grain beetle, to be of a similar order. All toxicity data were subjected to statistical analysis. Various methods suggested for the chemical evaluation of derris have been examined and discussed. Methods based upon optical rotation values have been shown to fail in the evaluation of roots and resins of different species, while the method of Jones and Smith (E. S. R., 77, p. 70), in which a definite toxic value is given to the nonrotenone fraction of the derris extract, has been found to be inadequate when applied to the roots under consideration. The determination of the percentage "rotenone equivalent" values of the roots, based upon the alkaline fractionation of the resins and the toxicities of the deguelin and toxicarol fractions relative to that of rotenone, has given a reasonably close estimate of the toxicities of the derris roots examined. The application of the method to the assessment of the toxic value of derris resins is described.

VI. The toxicity of *l*-elliptone and of poisons applied jointly, with further observations on the rotenone equivalent method of assessing the toxicity of *derris* root (pp. 69-81).—In continuation of the study of this problem, the assessment of toxicity by determination of the rotenone equivalent is shown successfully to apply to four of the derris roots examined in the work previously reported. Observations on the stability of the resins in ground roots stored in tins at room temperatures have been recorded. *l*-Elliptone has been shown to be one-fifth as toxic as rotenone to the chrysanthemum aphid when tested in an alcohol-saponin medium. The toxicities of poisons applied jointly have been examined, and the observed toxicities of mixtures of rotenone with a deguelin concentrate, *l*-elliptone, and *l*- α -toxicarol have been compared with those predicted from the potencies of the constituent poisons, but no significant synergistic or antagonistic effect has been found. The bearing of this upon the validity of the rotenone equivalent method of assessing toxicity is discussed.

A rotenone-bearing variety of *Tephrosia virginiana* in New Jersey, J. M. GINSBURG, J. B. SCHMITT, and T. S. REID. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 276-280).

Methyl bromide-dichloroethyl ether emulsion as a soil fumigant, C. G. LINCOLN, H. H. SCHWARDT, and C. E. PALM. (Cornell Univ.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 238-239).—Recent work indicates that a complete and

consistent kill of both larvae and adults of the alfalfa snout beetle at all levels can be obtained with a combination of methyl bromide and dichloroethyl ether emulsified with Aresklene. "To make this emulsion, equal volumes of the two fumigants and of water were taken. Aresklene was then dissolved in the water in an amount equal to 3 percent of the weight of the water. The dichloroethyl ether was added to the water and emulsified by shaking. In order to minimize loss by evaporation the methyl bromide cylinder was immersed in a mixture of ice and salt for about an hour before the material was drawn and added to the dichloroethyl ether emulsion. Only slight agitation was required to emulsify the methyl bromide. The amount of stock emulsion used on each 100 sq. ft. of soil was diluted with 5 gal. of water for use."

Results of the first test indicate that a dosage of 450 cc. of stock emulsion per 100 sq. ft. will give complete control of larvae and adults of the alfalfa snout beetle at all levels. At this dosage 1.5 cc. of each of the active ingredients are applied to each square foot of soil. Large amounts of water following application of the fumigant appear to be unnecessary. A second test, made in mid-October to determine whether dosages of less than 450 cc. per 100 sq. ft. would be effective, indicated that this dosage approaches the minimum which can be used against this insect, that 300 cc. is inadequate, and that 600 cc. is probably a safe dosage to recommend.

[The use of petroleum oils as insecticides.—IV,] The efficiency of dormant type oils in relation to their composition, G. W. PEARCE, P. J. CHAPMAN, and A. W. AVENS. (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 211-220, figs. 2).—A study made of the insecticidal efficiency of 39 petroleum oils of the dormant type, using the fruit tree leaf roller as the principal test insect, is reported in this fourth of the series (E. S. R., 86, p. 355). Correlations between efficiency in controlling this insect and various properties related to the constitution of the oils were observed. Data on viscosity, viscosity index, unsulfonated residue, density, refractive index, specific refraction, specific dispersion, and the "Waterman analysis" are given for each oil. These data show that an oil that is highly paraffinic in character and probably low in aromatic structures is the most desirable type for use in the control of the fruit tree leaf roller. Theoretical and practical implications of the results of the study are discussed.

Deposition of lead from lead arsenate spray mixtures and its retention on Pyralin plates and apple leaves and fruits, H. N. WORTHLEY and D. E. H. FREAR. (Pa. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 205-210, figs. 2).—The laboratory study reported revealed certain relationships in the deposition and retention of lead from various spray mixtures. Certain of these were substantiated by parallel field experiments. Further study is necessary to develop methods by which laboratory investigations of spray deposition and retention on artificial surfaces may safely be used to forecast field results with the same spray mixtures applied to various plant surfaces.

The grasshoppers and other Orthoptera of Arizona, E. D. BALL, E. R. TINKHAM, R. FLOCK, and C. T. VORHIES (*Arizona Sta. Tech. Bul.* 93 (1942), pp. [2]+255-373, figs. 15).—This publication includes 282 species and varieties of Orthoptera. Distribution, food plants, ecological associations, economic importance, and control measures are discussed. Illustrations and keys aid in generic and specific separation of the Arizona species. A bibliography is included which notes the more important publications on Arizona Orthoptera.

The relative effectiveness of dust mixtures against the German cockroach, J. E. DEWEY. (Univ. Tenn.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 256-261).—Laboratory studies on the relative effectiveness of dust mixtures

against the German cockroach, in which 41 different materials involving 89 tests were used, are reported.

Rearing grasshoppers under laboratory conditions, M. H. HAYDAK. (Minn. Expt. Sta.). (*Science*, 95 (1942), No. 2478, pp. 657-658).

The blueberry thrips, F. H. LATHROP. (Maine Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 198-201, figs. 3).—In experimental treatments for the control of the blueberry thrips *Frankliniella vaccinii* Morg., commenced in 1936, the most promising results were obtained from kerosene emulsion. On each of the three plats used the number of thrips-infested plants was greatly reduced by the treatment. The distribution of the infestation on the spring-treated plat suggests that the thrips that survived in this case may have been protected by the wooden frame. Ethylene dichloride emulsion and dichloroethyl ether appeared to be of little or no value. It is interesting to notice that there was a distinct and consistent increase in the number of infested plants on the plats treated with carbon disulfide emulsion. A somewhat similar effect was noticed in 1936, when there was an apparent increase in the number of thrips-infested plants on areas treated with flake naphthalene. None of the soil insecticide treatments caused injury to the blueberry plants, except that when kerosene emulsion was applied in both fall and spring the plants were severely injured. With a single treatment of kerosene emulsion, either fall or spring, no injury was noticed. In view of the satisfactory results obtained with kerosene emulsion, it is planned to continue the investigation in an effort to develop the treatment into a practical method for the control of *F. vaccinii*.

Orchard sprays and the white apple leafhopper, W. J. SCHOENE. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 220-222).—The studies here reported show that the fungicides in common use may actually reduce the number of white apple leafhoppers that mature, and that there is nothing to indicate that the sprays are beneficial to them. The results of certain tests not previously reported indicated that applications of nicotine to the foliage would reduce the number of leafhopper eggs that hatched, and that nicotine used in this experiment appreciably reduced the number of nymphs at dilution of 1:800.

Toxicities of bordeaux mixture, pyrethrum, and derris to clover leafhoppers, T. C. WATKINS. (Cornell Univ.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 234-236, fig. 1).—A series of immersion tests of adult clover leafhoppers (*Aceratagallia sanguinolenta* Prov.) in bordeaux mixture and aqueous suspensions of pyrethrum and derris is reported. The greatest kill obtained with derris was 52 percent at a concentration equivalent to 16 lb. of 5 percent rotenone per 100 gal., whereas 100-percent kill with pyrethrum was obtained at a concentration equivalent to 4 lb. of ground flowers containing 0.5 percent pyrethrins per 100 gal. Dosage-mortality curves for results of tests with pyrethrum and derris are presented, as are also comparisons of these results with those obtained in previous tests on potato leafhoppers.

The Taxus mealybug *Pseudococcus cuspidatae* Rau, C. C. HAMILTON. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 173-175, fig. 1).—For several years the mealybug *P. cuspidatae* has been a serious pest of evergreens of the genus *Taxus* in nurseries and ornamental plantings in New Jersey, and in some instances has become so abundant as almost to cover the trunk and the principal branches and occur in masses where the twigs branch, furnishing roughened places favorable for them to develop. It is usually found more abundantly on those species with dense foliage such as *T. cuspidata nana* and *T. cuspidata wardii*. It is also reported as having been collected in the adult stage on apple, basswood, cedar, maple, and rhododendron, although it probably does not breed on these plants. A comparison made in June 1940 of

several materials to determine their effectiveness in the field revealed all of these spray materials, when thoroughly applied, to give a good kill of the mealybugs. The nicotine and soap spray was distinctly better than the other materials, no injury to any of the plants resulting from its application. A miscible carbolineum spray applied in the nursery during the summer of 1941 at a dilution of 1 to 100 parts of water also gave a good kill of mealybugs without injury to the plants. Control of the mealybugs in the dormant period has not as yet been investigated.

Further notes on the control of the pea aphid, H. G. WALKER and L. D. Anderson. (Va. Truck Expt. Sta.). (*Va Acad. Sci. Proc.*, 1941, p. 184).—An abstract of a contribution on further work with the pea aphid (E. S. R., 84, p. 80; 85, p. 375).

Transmission of potato virus Y by *Aphis rhamni* (Boyer), B. KASSANIS (*Ann. Appl. Biol.*, 29 (1942), No. 1, p. 95).—Transmission experiments, summarized in an accompanying table, have shown that, in the greenhouse at least, *A. rhamni* is as efficient a vector of potato virus Y as the green peach aphid, and that it reacts to a preliminary starving period in the same way.

The present threat of westward spread of the gipsy moth, H. L. MCINTYRE (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 171-173).

Studies on rotenone and other organic insecticides for codling moth control, S. W. HARMAN. (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 223-224).—The results of a series of field experiments conducted during the past 4 yr., in which rotenone-bearing materials and certain other organic compounds were tested against the codling moth under conditions of severe infestation, are reported. It is pointed out that the field of usefulness for organic insecticides has steadily increased. Nicotine sprays have been accepted as offering a practical means of combating the codling moth, and more recent tests have shown that the powdered rotenone-bearing roots promise to be useful additions to the apple spray programs. The latest tests have indicated that rotenone is not only valuable as a primary insecticide, but especially promising results have been secured when the powdered root has been used in combination with other materials.

Extracts of apple peels as adjuvants to lead arsenate against the codling moth larva, E. H. SIEGLER and H. A. JONES. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 225-226).—In work in the laboratory lead arsenate combined with alcoholic extracts of apple peels, from both ripe and green apples, was compared with lead arsenate alone against the newly hatched codling moth larva. The alcoholic extracts were purposely varied with respect to their content of nonvolatile extractives. Extracts which contained only small quantities of nonvolatile extractives did not significantly increase the effectiveness of lead arsenate, but extracts with higher concentrations did improve its significance.

An investigation of the mineral oil treatment for corn earworm control, L. A. CARRUTH. (N. Y. State Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 227-233, fig. 1).—An investigation of the mineral oil treatment and its modifications, conducted during the 4-yr. period from 1938 to 1941 in Nassau County, N. Y., on western Long Island, is reported, the details being given in eight tables. This oil treatment involves the deposition of a small quantity of highly refined white oil, usually of U. S. P. grade, in the "silk channels," within the husk tips, of developing sweet corn ears between the tip of the cob and the exterior. This forms an insecticidal barrier between the earworm larvae and their preferred food. The effectiveness and practicability of this treatment may be influenced by a number of factors, of which the following

are discussed: Dosage per ear, ear tip stunting, the value of added insecticides, insecticide concentrations, oil viscosity, oil refinement, time of application, and crop uniformity.

The findings have led to the conclusion that such treatment has provided a more nearly satisfactory means for controlling the corn earworm than methods previously investigated, including insecticidal sprays. Special technics have been developed for the application of the oil treatments and the recording of experimental data. A mineral oil of U. S. P. quality with a viscosity between 175 and 210 Saybolt sec. (100° F.) was found most satisfactory for general use, since oils of lower viscosities produced excessive ear tip stunting. It was indicated that oils having viscosities as low as 125 sec. might prove acceptable as lower effective dosages per ear are established. A single treatment at a dosage between 0.5 and 0.6 cc. per ear should give relatively good earworm control, and dosages as low as 0.25 cc. proved effective in certain experiments. A preliminary investigation indicated that oils of slightly less refinement did not differ significantly in performance from highest U. S. P. quality oils, although, as yet, they should probably not be substituted for the latter. The addition of an insecticide definitely increased the effectiveness of the mineral oil treatment and, at ordinary dosages, did not significantly increase the amount of ear tip stunting. Relatively good control was obtained with oil containing as low as 0.1 percent pyrethrins or 1 percent dichloroethyl ether, although double these quantities have usually been suggested. Oil insecticide treatments applied 5 to 7 days after silking were relatively effective. Treatments applied even later gave relatively good control in certain tests, although a danger of greater earworm injury was found when heavy infestations were present.

Methyl bromide fumigation for control of the narcissus bulb fly, F. S. BLANTON. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 239-241).—The study reported indicates that methyl bromide is an effective fumigant for the control of narcissus bulb fly larvae. Incidental records indicated that this treatment is also effective against the lesser bulb fly larvae and the bulb mite. The bulbs will tolerate a 3-lb. dosage at 70° F. for 4 hr. without harmful effects. With proper fumigation equipment this will constitute a rapid method of treating bulbs, and after additional mortality records are taken a shorter treatment possibly may be recommended which will speed the process of fumigation on a commercial basis.

Effect of sesamin and related compounds on the insecticidal action of pyrethrum on houseflies, H. L. HALIFE, F. B. LAFORGE, and W. N. SULLIVAN (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 247-248).—The results thus far obtained in work with sesamin and related compounds indicate that an important practical field has been opened which may lead to the discovery of other synergists perhaps more active and readily available than sesamin or asarinin.

The increasing importance of coleopterous borers in shade trees, E. P. FELT and S. W. BROMLEY (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 169-171).

The influence of host plants on the local distribution of Japanese beetles and on the effectiveness of traps, F. B. WHITTINGTON, E. N. CORY, and G. S. LANGFORD (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 163-164).—The experiments considered are offered as further evidence of the influence of hosts on the local distribution of Japanese beetles and on the effectiveness of traps. In one experiment involving the use of 25 Japanese beetle traps, a row of 5 traps, 50 ft. apart and 10 ft. from the border of a rose garden, trapped over 2.5 times as many beetles as any of the other similar rows of traps at 160, 310, 460, or 610 ft. distance. A second series of experiments involved the use of 114 traps

distributed in six towns. The 57 traps spaced 100 ft. from the host plants averaged 297 beetles, while the same number at 10 ft. averaged 847, or approximately 2.8 times as many. The tests indicate that traps operated 5 to 10 ft. from preferred hosts catch from 2 to 2.5 times as many beetles as traps operated 100 ft. from hosts. Further interpretation of the results leads to the conclusion that traps are not responsible for the large number of beetles on some properties and the relatively small number on adjoining properties, but that this variation in population is due primarily to the kind and abundance of host plants.

The adult Japanese beetle as host and disseminator of type A milky disease, G. S. LANGFORD, R. H. VINCENT, and E. N. COBY. (Univ. Md.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 165-169).—The results obtained in experimental work with the type A milky disease organism (*Bacillus popilliae*) indicate that the adult Japanese beetle is a host for this organism, a factor in the spread of the disease, and a possible medium for the propagation of spores for use in its artificial spread.

Control of native white grubs in young hemlocks, H. H. SCHWARDT. (Cornell Univ.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 176-177, fig. 1).—The results of a series of soil treatments applied during the summer of 1941 for the control of outbreaks of native white grubs which had occurred in several parts of New York State, causing heavy damage to young evergreens in both nurseries and reforestation plantings, are briefly noted. Of the five insecticides tested, the paradichlorobenzene treatment gave the best results.

Protecting lawns from injury by grubs, F. L. GAMBRELL and A. B. BUCHHOLZ (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, p. 3, figs. 2).—A practical account.

Descriptions of the larvae of some West Indian melolonthine beetles and a key to the known larvae of the tribe, A. G. BÖVING (*U. S. Natl. Mus. Proc.*, 92 (1942), No. 3146, pp. 167-176, pls. 2).

Controlling rose chafer, R. HUTSON and F. SHERMAN III (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 292-294, fig. 1).—Experimental work indicates that pyrethrum sprays and dusts are satisfactory for the control of the rose chafer. Pyrethrum sprays should contain a good wetting agent and be used at the rate of 1 pt. of 0.2 percent pyrethrin content spray per 100 gal. Heavy lime sprays will prevent reinfestation on fruit trees.

Laboratory tests with insecticides against the tobacco flea beetle, G. WENE and C. B. DOMINICK. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 183-184).—Description is given of a method for comparing the effectiveness of insecticides against the tobacco flea beetle. A total of at least 200 beetles in all were used at each of several dilutions. A dilution of 1 gm. of the insecticide to 50 gm. of solution gave a calculated residue of 0.0128 mg. per square centimeter of leaf surface. At this dilution rotenone showed a kill of 99.12 percent at the end of 24 hr. At the end of 72 hr. basic copper arsenate had killed 80.89 percent of the beetles, cryolite 55.87, Dutox 59.57, lead arsenate 39.30, and phenothiazine 8.29 percent. As indicated in the data presented, the rotenone continued to be effective at dilutions up to 1:1,200. On the other hand the kill with the arsenicals was greatly reduced at dilutions of 1:100 and 1:200. The tobacco flea beetles did very little or no feeding on the rotenone-treated leaves, which indicates that rotenone probably acts by contact.

Life history of the wireworm *Aeolus mellillus* (Say), H. H. JEWETT (*Kentucky Sta. Bul.* 425 (1942), pp. 11, fig. 1).—*A. mellillus* was found to be parthenogenetic under Kentucky conditions. Overwintering adults produced eggs

from early May until after the middle of September. Larvae from some of these eggs produced adults the same season, the period from egg deposition to the adult stage averaging about 75 days. Some of the early appearing adults oviposited eggs for a second generation of wireworms. The time from egg laying to the adult stage for overwintering wireworms ranged from 276 to 369 days. Overwintering larvae cause heaviest damage to spring-planted crops. Since most of these larvae pupate by June 30 in central Kentucky, late-planted crops are more likely to escape heavy injury than crops planted earlier. Unplowed sod is the preferred place for oviposition, and, since egg laying begins about May 1, crops planted on sod land plowed earlier in the spring are less likely to be injured than those planted on late-plowed sod land. Cultivated land kept clean the year following sod and sowing small-grain cover crops as late in the fall as practical will largely prevent infestation with larvae the second year.

The sweet clover weevil, J. A. MUNRO and H. S. TELFORD (*North Dakota Sta. Bimo. Bul.*, 4 (1942), No. 6, pp. 21-22).—A practical account of a new and serious pest of sweetclover, *Sitona cylindricollis* (F.).

Pellet bait for control of the alfalfa snout beetle, C. G. LINCOLN. (Cornell Univ.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 236-237).—In control work with the alfalfa snout beetle, soybean meal-granulated sugar-sodium fluosilicate bait was highly effective when the bait was pressed into pellets by putting it through a power meat grinder but much less effective when not pressed into pellets. Under conditions prevailing in northern New York in April and May a bait must remain moist and attractive to the beetles during periods of hot, cold, cloudy, and, if possible, rainy weather. The meal bait dries out rapidly and sifts into the dust and trash on the soil surface, whereas the pellet bait withstands drying and the pellets are large enough to stand up above the trash and dust.

Some observations of *Ips* bark beetle attack on pine trees, L. A. HETRICK. (Va. Expt. Sta.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 181-183, figs. 2).—A study of four species of bark beetles of the genus *Ips*, which attack growing pine trees, has indicated that trunk and crown injuries, root injuries, and reservoirs of infestation are responsible for many killings. In other cases no apparent reason could be found for attack of apparently healthy pine trees. Because of the similarity of these killings to killings that could be attributed to root injuries, it is suggested that some unknown root condition may be responsible for the attractiveness of the trees to bark beetles.

Toxic and repellent sprays for the control of elm bark beetles, R. R. WHITTEN (*U. S. Dept. Agr. Cir.* 647 (1942), pp. 12, figs. 2).—Nineteen spray formulas containing naphthalene flakes, orthodichlorobenzene, chlorinated naphthalene, diphenyl flakes, and pentachlorophenol were experimentally tested for their toxic or repellent action to the two principal elm bark beetles, namely, the smaller European elm bark beetle and the native elm bark beetle. The cost per gallon ranged from 12 to 55 ct. All sprays were applied to the outer bark of infested or noninfested elm logs until the entire surface was thoroughly wetted. In the toxicity tests the age of the brood and bark moistures from 80 to 189 percent had no deleterious effect on the results. Air temperatures above 50° F. were conducive to more uniform results. Orthodichlorobenzene and monochloronaphthalene were the two most effective toxic and repellent materials. Good repellency was obtained from one application for an entire active season. Several of the mixtures were applied to tightly stacked 1-cord piles of elm logs under field conditions with good results in respect to repellency and kill. The cost of materials per cord ranged from 49 to 78 ct.

Reactivation of *Ceratostomella ulmi* in occluded infections and contamination of *Scolytus multistriatus*, W. D. BUCHANAN and S. J. SMUCKER. (U. S. D. A.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 178-180).—Little evidence was obtained through experimentation of the reactivation of the Dutch elm disease fungus *C. ulmi* through feeding injuries made by 11,400 smaller European elm bark beetle adults. The results show that these beetles may become contaminated with *C. ulmi* as a result of their feeding in the trunks and crotches of elms with active or occluded infections.

Preliminary investigations on the value of electric heating of beehives, C. G. BUTLER and G. F. COCKBILL (*Ann. Appl. Biol.*, 29 (1942), No. 1, pp. 34-42).

Studies of the mite *Eupitimerus hystrix* Nalepa on timothy, B. B. PEPPER. (N. J. Expt. Stas.). (*Jour. Econ. Ent.*, 35 (1942), No. 2, pp. 201-204, figs. 3).—This contribution relates to *E. hystrix*, first recorded in the United States at Arlington, Va. It first came to attention and was a serious pest in timothy fields in the Freehold area of Monmouth County, N. J., in the spring of 1938. By 1939 it had spread into Middlesex, Ocean, Atlantic, and Mercer Counties, and by 1940 several timothy fields in Burlington, Somerset, and Hunterdon Counties were seriously damaged. In 1941 specimens were collected in every county in the State, and the injury was quite severe. Only timothy and orchard grass (*Dactylis glomerata*) have been found as hosts of the mite, which prefers to feed on the tender growing tips of the timothy plant, since most of the mites have been found on the unfolding leaves. Little is thus far known of its life history and habits. The most promising control measure for the mite is pulverized calcium cyanamide and sulfur dust. Cyanamide acts as a contact poison to the mite and also as a fertilizer for the crop. Sulfur destroys a large percentage of the mites, but does not possess the stimulating effects on the crop of cyanamide. Rotenone dust did not prove effective against the mite. Oil emulsions and two dinitro compounds in dust form caused severe reductions in yield. Burning over the timothy fields before growth begins in the spring has proved unsatisfactory.

ANIMAL PRODUCTION

[Livestock investigations by the Florida Station] (*Florida Sta. Rpt. 1941*, pp. 59-60, 62, 63-64, 65-67, 68-69, 167, 176-177, 185-188, 189, figs. 4).—Brief results are presented by W. M. Neal, L. L. Rusoff, W. G. Kirk, D. J. Smith, A. L. Shealy, N. R. Mehrhof, E. F. Stanton, D. F. Sowell, O. W. Anderson, Jr., R. M. Crown, J. C. Driggers, R. E. Blaser, F. T. Boyd, R. W. Kidder, V. E. Whitehurst, Jr., and J. D. Warner of projects on the cobalt and copper supplied cattle by forage; grazing tests of Napier grass with beef cattle; deficiencies of peanuts as a feed for swine; vitamin D of shark-liver oil for poultry; the comparative value of sugarcane silage, shocked sugarcane, and pasture supplemented with cottonseed meal or cottonseed cake for wintering beef cattle; methods of feeding grain to layers; molasses for fattening steers; the use of laboratory animals for mineral nutrition problems of livestock; rotational grazing and internal parasites in sheep production; feed requirements for hogs of various market grades; calcareous mineral supplements for poultry breeding; biological analysis of fertilized and unfertilized pasture herbage; pasture investigations on peat and muck soils of the Everglades with beef cattle; fattening steers on winter pastures with ground snapped corn, ground shallu heads, molasses, and cottonseed meal; copper, cobalt, and aluminum requirements of beef cattle; feed crop production and utilization with beef cattle; kudzu and peanut hays for fattening steers; Brahman and Angus steers as feeder cattle; effect of varying amounts of roughage in feeds on finish and quality of Hereford steers; and oats pasture as a

supplement to corn and tankage and mineral supplements in rations for fattening hogs.

[Livestock experiments by the Kentucky Station] (*Kentucky Sta. Rpt. 1941*, pp. 22, 23-25, 26, 46).—Results are briefly presented on investigations of rye v. bluegrass and alfalfa hay v. red clover hay for pregnant ewes; continuous and rotational grazing of bluegrass pastures by ewes and lambs; comparison of sheared and unsheared lambs; creep-feeding cracked corn for suckling lambs; comparative tests of castrating and docking lambs; alfalfa-molasses silage v. alfalfa hay for steers; comparison of distillers' corn dried grains v. cottonseed meal for beef cows; relationship of relative humidity to hatchability of turkey eggs; different methods of feeding protein supplements to poultry; the relation of a hen's ration to the egg yolk fat during incubation; and carrying capacity of fertilized and unfertilized pastures for beef cattle.

[Livestock production by the Wyoming Station] (*Wyoming Sta. Rpt. 1941*, pp. 11, 12, 25-27, 33, 37-38).—Results are briefly recorded on investigations of the relation of protein to egg production in poultry; the growth and quality of meat of turkeys fed different grain rations; deficiencies in calcium and phosphorus in cattle rations; variations in the quantity and relation of scoured wool to price; the use of fiber coats for sheep; different roughages for wintering beef calves; different kinds of housing for egg production; rations for fattening lambs; and wet beet pulp v. silage for steers.

Filling the silo with corn or sorghum, J. E. COMFORT (*Missouri Sta. Cir. 239* (1942), pp. 4).—General directions are given for filling, cutting, and harvesting corn and sorghum for the silo.

Vitamins in live stock feeding—1942, T. S. HAMILTON. (Univ. Ill.), (*North Amer. Vet.*, 23 (1942), No. 5, pp. 306-308).—There are tabulated the effects and sources of the various vitamins essential in livestock and poultry nutrition.

Alfalfa hay, war-important feed, is shown to vary considerably in mineral makeup, J. W. TORSKA, C. E. VAIL, and E. DOUGLASS (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 3, pp. 24-26).—The authors point out the considerable variability of alfalfas with respect to mineral nutrient content, tabulating the minimum content, content of good alfalfa, and the maximum content found for the following ash components: Silica, sulfates, carbonates, phosphates, chlorides, calcium, magnesium, potassium, and sodium. It is emphasized that the highest silica content found, about 0.75 percent, is very much lower in proportion to the total ash content than is that of most grass hays, and the nutrient mineral content correspondingly greater.

Commercial feeding stuffs, L. S. WALKER and E. F. BOYCE (*Vermont Sta. Bul. 478* (1941), pp. 64).—The usual report (*E. S. R.*, 86, p. 227) of the guaranty and found analysis of 1,931 official samples of feeds collected in Vermont in April and August 1941, with a statement regarding those samples failing to comply with their guaranteed analyses and the presence of deleterious and toxic material.

Synergism between thyrotropic and growth hormones of pituitary. Body weight increase in hypophysectomized rat, W. MARX, M. E. SIMPSON, and H. M. EVANS. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 594-597).—A synergistic effect of purified growth hormone when given with thyrotropic hormone to hypophysectomized rats was noted by an increase of 22.1 gm. in 15 days from the growth hormone alone, 31.8 gm. from the combination, but only 5.9 gm. when thyrotropic hormone was administered alone. The study was conducted with 3 lots of 21, 28, and 29 hypophysectomized rats each with one hormone or the other or a combination, and with 1 lot of 13

[Investigations with beef production by the Arizona Station] (*Arizona Sta. Rpt. 1941, pp. 37-39, 43-44*).—Brief results are presented of feeding experiments of Manko—a new grain sorghum—silage v. hegari silage, molasses mixed with hay and silage, grapefruit refuse silage, whole cottonseed v. cottonseed meal, hegari silage in a standard fattening ration, pasturing alfalfa and alfalfa barley mixtures; and relationships of judging points, body measurements, color, bone, etc. of carcass quality in steers.

Cattle feeding test at Akron indicates good method of marketing dryland feed, R. C. TOM (*Colo. Farm Bul. [Colorado Sta.], 4 (1942), No. 3, pp. 14-16, figs. 2*).—An improved variety (Coes) of sorghum grain proved to be 89 percent as efficient as corn when fed alone to Hereford steers and 92 percent as efficient as corn in a grain mixture. Steers fed Coes sorghum grain showed less finish and desirability of carcass than the best steers receiving a grain mixture with sorghum silage which produced a high finish. Calculi were found in many of the steers.

Feeding experiments with beef cattle to determine nutritive values of first-, second-, and third-crop alfalfa hay, F. B. HEADLEY. (Coop. U. S. D. A.). (*Nevada Sta. Bul. 161 (1942), pp. 17, figs. 5*).—In 4 years' experiments first, second, and third cuttings of alfalfa hay were compared for beef cattle. The first cutting generally proved superior to the second cutting in all hay rations fed during the first 8 weeks. Differences between the first and third cuttings were not significant. When the different cuttings were fed comparatively to steers or heifers in 8-weeks fattening periods with a grain ration of barley and beet pulp, the results for all the years were in general most favorable to the first cutting of alfalfa, although equal gains were produced by those receiving the third crop hay. There was no significant difference in the first year from whole or chopped hay, but chopped hay only was fed during the last year. The results were based on the progress made by groups of eight head of steers or heifers individually fed with each type of hay. Data are included on the chemical composition and mineral content of the hays of each cutting in the several years and an estimation of the hay and grain required by fattening beef cattle.

Mineral study under way seeks method of best supplying needs of beef cattle, A. E. CULLISON (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 7, p. 8*).—A discussion of mineral deficiencies encountered in livestock feeding and plans of a mineral experiment under way.

Sweetpotato meal versus corn for finishing calves, A. E. CULLISON (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 7, pp. 1, 7*).—In a feeding test of 142 days' duration 6 steer calves were finished on a ration of dehydrated sweetpotatoes, cottonseed cake, sorghum silage, and Johnson grass hay making average daily gains of 2.07 lb. Another group of 10 steer calves with corn replacing the dried sweetpotatoes made average daily gains of 2.29 lb. with slightly less cottonseed meal consumed. These results indicated that the dehydrated ground sweetpotatoes have considerable promise as a cattle fattening feed.

Rations for ewes in lambing camp, H. HACKEDORN, H. P. SINGLETON, and W. H. BURKITT (*Washington Sta. Bul. 413 (1942), pp. 22, figs. 2*).—Feeding groups of 20-30 ewes with lambs during 1937, 1938, and 1940 at the Prosser Substation showed no significant differences between potatoes, sugar beets, rutabagas, or beet molasses. It was calculated that on the basis of alfalfa hay potatoes were worth 15-25 percent as much; sugar beets 35; and wet beet pulp 6.5-7.5 percent. Beet molasses showed injurious effects both when utilized as the only concentrate and when fed with corn or barley. Cane molasses and oats on a replacement basis of pound for pound was slightly inferior to oats alone. There was no significant difference in results between oats and peas when fed with beet molasses.

Mississippi-grown feeds for fattening pigs, P. G. BEDENBAUGH (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 7, pp. 1, 2*).—In experiments involving 5 lots of 10 pigs each fed for about 50–60 days average daily gains of 1.12 lb. were produced with sweetpotato meal and tankage. Rations of corn or barley and tankage produced average daily gains of 2.14 and 1.85 lb. per head, respectively. When the rations consisted of commercial and home-grown oats with the tankage the average daily gains were 1.52 and 1.35 lb., respectively. The calculated values of the different feeds, based on their conversion into pork, were estimated.

Proso, corn and barley as feeds for hogs on alfalfa pasture, F. W. CHRISTENSEN, P. E. JOHNSON, A. SEVERSON, E. P. PAINTER, and T. H. HOPPER (*North Dakota Sta. Bul. 318 (1942), pp. 13*).—In experiments conducted over a 3-yr. period on alfalfa pasture with approximately 30 pigs on each grain, singly and in combination, it was found that the best rate of gain, 1.5 lb. per head daily, was made with corn and proso with the protein supplement of tankage and linseed meal 2:1. Almost equal rates of gain were made with barley and corn but with proso as the single grain concentrate the average daily gains were reduced to 1.13 lb. Proso alone seemed somewhat less palatable than barley or corn, required more feed per unit of gain, and produced smaller gains. Barley produced a somewhat firmer carcass than corn but proso produced a softer fat although not objectionable.

Soybean oil meal and pasture with corn for pigs, V. A. FREEMAN (*Michigan Sta. Quart. Bul., 24 (1942), No. 4, pp. 310–312*).—There are briefly reported the results from feeding pigs averaging about 40 lb. of weight to final weights of approximately 200 lb. The results showed that pigs prefer heat-treated or roasted soybean meal to raw solvent process meals. The average daily gains when the supplements consisted of tankage, expeller, raw solvent, or roasted solvent soybean meal were respectively 1.29, 1.34, 1.08, and 1.23 lb. per head. In another experiment soybean flake was higher in protein content but no more palatable to pigs under 100 lb. than the expeller product.

Peanut meal in the swine ration, Z. A. MASSEY, T. S. BOGGESE, JR., and K. T. HOLLEY (*Georgia Sta. Cir. 138 (1942), pp. 7*).—In two experiments with lots of 7 and 8 pigs each economical results were obtained with peanut meal and tankage as a supplement to corn. In the first trial the average daily gain per head with corn and tankage was 1.53 lb., while with peanut meal and tankage mixed about 9:1 it was 1.83 lb. About 3.5 lb. of feed were required per unit of gain. In a second experiment a protein mixture of 19 parts peanut meal to 1 part tankage produced average daily gains of 1.55 lb. as compared with 1.64 lb. by pigs on a 9:1 protein mixture. Failure accompanied attempts to self feed a mixture of three parts peanut meal and one part corn but the mixture was satisfactorily hand-fed as a slop.

Methods of hastening absorption of salt in farm-cured ham, P. T. ZEIGLER and R. C. MILLER (*Pennsylvania Sta. Bul. 427 (1942), pp. [1]+8, figs. 2*).—Supplementing previous curing studies (E. S. R., 79, p. 377), the optimum curing period for hams pumped with 10 percent of their weight with 75° pickle and cured in a cover pickle of the same strength proved to be 2.5 days per pound. Unpumped hams required 4 days more per inch of ham. When the hams were sharp frozen they could be left in the pickle without thawing. They absorbed salt as rapidly in both the 75° and 85° pickle as thawed hams and it was advantageous in keeping down the temperature. Forcing the pickle into the center of the ham reduced the curing time about three-fourths to 1 day per pound of ham. Unchilled hams were successfully dry sugar cured at a room temperature of 65° F. in 2.5 days per pound. In the conduct of this study the penetration of the 75° and 85° brine into 1-in. slices of ham removed at

6-9 day intervals were ascertained following the different treatments. Tenderizing ham by arterial curing with 10 percent of a 60° pickle was accomplished in 12-15 days regardless of the size of the ham employed. Smoking and the production of ready-to-eat hams are discussed.

[Studies with poultry nutrition by the Massachusetts Station] (*Massachusetts Sta. Bul.* 388 (1942), pp. 97-98, 99).—Results are briefly reported by R. T. Parkhurst, M. S. Gutowska, C. R. Fellers, E. M. Parrott, R. M. Verberg, W. C. Sanctuary, C. I. Gunness, and J. H. Vondell of investigations in comparing crab meal and fish meal for poultry rations; the effect of excesses of calcium in the poultry diet; sources of calcium, including calcite flour, for laying hens; electric brooding; and restricted feeding with range for pullets and hens.

Poultry products research: A guide for research workers, including a list of some problems in project form, edited by G. F. STEWART (*Iowa Sta. Res. Bul.* 299 (1942), pp. 697-773).—Important problems in the scientific research and technical control of poultry products are outlined in project form as to significance, personnel and facilities, and suggested procedure as a service in creating new uses and the development of new standards and as a guide for new workers. Twenty-four egg and 28 poultry projects are presented. There were 51 contributors.

War-time poultry feeding, E. T. HALNAN ([*Gt. Brit.*] *Min. Agr. and Fisheries "Growmore" Bul.* 5 (1942), pp. II+9).—Very popular and brief instructions are given on rations for rearing, growing, and laying poultry, with suggestions on substitute feeding stuffs for wartime. A brief statement is included on feeding ducks and geese.

Feeding systems for laying hens, E. W. CALLENBACH and R. R. MURPHY (*Pennsylvania Sta. Bul.* 425 (1942), pp. [2]+26, figs. 6).—In 3 yr. comparisons of different methods of feeding laying hens as affecting production, weight, and mortality the maintenance of a high total feed intake of a well balanced mash and sensible grain mixture or individually fed grains rather than the ratio between grain and mash or high mash consumption seemed to be the critical feeding factor in the experiment. The feeding of wet mash and condensed buttermilk did not improve biological performance but increased the labor requirement. Free-choice grain feeding permits the most efficient use of available labor. Feeding at least part of the grain in the litter helps to keep it in better condition. These experiments were conducted with 7 lots of 40 White Leghorn hens each from September 1936 to September 1937, and 7 lots in 1937-38 and 8 lots in 1938-39 of 50 Barred Plymouth Rock hens each. The influence of free-choice and limited feeding of grain in different combinations were compared. Results in general equal, but neither superior nor inferior, to those with a standard 18.5 percent protein mash were obtained with a high protein (31.5 percent) mash and a free choice grain mixture.

Growing chickens, W. M. VERNON, W. R. WHITFIELD, and H. L. WILCKE (*Iowa Sta. Bul.* P47, n. ser. (1942), pp. 529-552, figs. 18).—General directions are given for growing, feeding, and management of chicks from day old to laying age, including methods of brooding and provisions necessary for the inclusion of the essentials of growth in poultry.

Percentage utilization and supplementary relationships of certain protein concentrates in semi-purified basal diets for growing chickens, A. H. VAN LANDINGHAM, T. B. CLARK, and B. H. SCHNEIDER. (*West Va. Expt. Sta.*). (*Poultry Sci.*, 21 (1942), No. 4, pp. 346-352).—In balance trials with 7-18 6-week-old White Leghorn chickens the protein utilization of protein concentrates fed were practical growing ration 76.2 percent, soybean meal 76, dried whole egg 74.2, casein 58, menhaden fish meal 57, meat scraps 41.9, and corn gluten meal

28.7 percent. There was essentially no supplementary value to the proteins of menhaden fish meal with meat scrap or soybean meal but about 12–18 percent supplementary value was found for corn gluten meal with meat scrap, soybean meal, and menhaden fish meal. Meat scrap and soybean meal showed a similar supplementary value. The study was conducted in individual cages with the birds force fed with each trial consisting of a 3-day preliminary period and a 17-day collection period. Protein utilization was calculated from the nitrogen intake and nitrogen excretion.

Glycine requirement of the chick, H. J. ALMQUIST and E. MECCHI. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 541–543).—When added to the basic diet for the chick used in previous experiments (E. S. R., 86, p. 666), glycine as 1.5 percent produced optimum growth but 2 percent caused a reduced gain. When provided in combinations as in gelatin, edestin, casein, and glycyglycine, 1 percent of glycine gave optimum growth of about 7 percent in weight per day. Two experiments were conducted with supplements of the pure or combined glycine rations with five or six chicks per lot in 10- or 11-day feeding periods.

Green range will provide essential poultry feed to replace that made scarce by war, H. S. WILGUS, JR. (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 3, pp. 3–4, fig. 1).—Winter rye and wheat followed by oats and later Sudan grass are recommended for growing and breeding flocks of chickens and turkeys and the control of parasites.

Feeding-cane molasses as a constituent of poultry rations.—I, Molasses for growing chickens, W. H. ORT, R. V. BOUCHER, and H. C. KNANDEL. (Pa. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 340–345).—In contributing further to studies of cane molasses in the poultry ration (E. S. R., 78, p. 524), two experiments were conducted with about 1,000 chickens fed through the growing period on rations containing 0, 2, 4, and 6 percent of cane molasses. The chicks hatched from the eggs produced the first year were continued to 12 weeks of age on the same rations. The 4-percent cane molasses diet had a slight early growth-stimulating effect on both sexes, but feed efficiency was lowest in the molasses-fed groups. The feed intake per bird was significantly greater for those on the 4- and 6-percent cane molasses rations than when smaller amounts of molasses or no molasses were available.

Absorption and disposition of glucose in the chick, W. R. C. GOLDEN and C. N. H. LONG (*Amer. Jour. Physiol.*, 136 (1942), No. 2, pp. 244–249).—There was an absorption rate from the intestinal tract of about 400 mg. per hour per 100 gm. of body weight for glucose administered in four concentrations to 44 birds and allowed to absorb for 1, 2, 3, or 4 hr. The gastrointestinal tract of the fasted fowl did not contain significant quantities of reducing material, and nearly all of the glucose could be recovered immediately after administration. Twelve percent of the glucose could be accounted for in 4 hr. as increased liver glycogen, but not more than 8 percent was estimated to have been deposited in the muscles. The chick has a relatively intense ability to oxidize glucose or to convert a considerable portion into fat.

Studies in mineral nutrition of laying hens.—II, Excess of calcium in the diet, M. S. GUTOWSKA and R. T. PARKHURST. (Mass. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 321–328, figs. 3).—Continuing this series (E. S. R., 87, p. 559), feeding hens all mash rations containing 2.35–3.95 percent calcium with normal phosphorus and ample vitamin D showed that the excessive calcium lowered egg production and feed efficiency. The breaking strength of the eggs was more closely related to the manganese content of the diet than to the calcium levels. The experiment was conducted in two 6-mo. periods

with all mash rations fed to caged Rhode Island Red pullets to which supplements of 2, 4, and 8 percent calcite flour were added. With the ration containing 3.95 percent calcium the percentage egg production was 49.1, as contrasted with 68 percent for those receiving 2.35 percent calcium in the ration. However, there were no significant differences in the average eggshell breaking strength, egg weight, fertility, and hatchability of the eggs from groups receiving varying levels of calcium. The equation of Titus et al. (E. S. R., 77, p. 530) for estimating the calcium requirements of the laying ration was confirmed.

Magnesium requirement of the chick, H. J. ALMQUIST. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 544-545).—The effect on growth of supplementing the purified chick ration (E. S. R., 86, p. 666) with 250, 350, and 450 p. p. m. of magnesium suggested that during the first week of life the chick requires about 400 p. p. m. of magnesium. These studies were conducted with 5 lots of 10 chicks each, reared for 17 days on the ration supplemented as indicated.

The vitamin B₆ requirement of the chick, G. M. BRIGGS, JR., R. C. MILLS, D. M. HEOSTED, C. A. ELVEHJEM, and E. B. HART. (Wis. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 379-383, figs. 2).—Continuing studies of vitamin B₆ in the nutrition of the chick (E. S. R., 83, p. 533) varying levels of vitamin B₆ were fed for about 3 weeks, indicating that the birds needed approximately 275-300 µg. per 100 gm. of the ration for optimum growth. These results were ascertained by determination of the growth of chicks on basal rations and after additions of up to 400 µg. of the crystalline vitamin. Correlations with results obtained with rats and in Jukes' studies with poultry (E. S. R., 82, p. 378) showed close agreement.

Metabolism and food utilization of riboflavin-deficient chicks, M. KLEIBER and T. H. JUKES. (Univ. Calif.). (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 1, pp. 34-37).—Respiration trials with groups of riboflavin-deficient and adequately supplied chicks showed that riboflavin deficiency decreased the utilization of protein but did not affect the utilization of feed energy beyond decreasing the appetite. The study was conducted with groups of 10 chicks each with and without riboflavin supplements for 10-day periods. For every 100 k calories (100,000 calories) gain in energy the flavin-deficient chicks gained 2.3 ± 0.7 gm. nitrogen, whereas the controls with adequate riboflavin gained 5.1 ± 1.4 gm. Thus they gained protein while losing body fat.

Modifications in the chick vitamin D assay procedure, S. R. JOHNSON. (Ark. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 329-332).—Analysis of the right and left tibia of 160 chicks showed the removal of the epiphyseal cartilages to facilitate rapid and complete removal of adhering tissue from the bone. The mean difference between the bone ash in these two cases showed that about 8.5 percent more accurate and complete results were obtained than from the opposite side in which the cartilages were intact. Different vitamin D supplements were included in the rations, and it was found that differences in the ash percentage were usually greater after 3 than after 4 weeks' feeding. The 3-week feeding period was preferred on the basis of the coefficients of variations. A 150 unit level of vitamin D seemed needed for the development of straight keels at 4 weeks of age.

The relation of biotin to perosis in chicks, L. R. RICHARDSON, A. G. HOGAN, and O. N. MILLER (*Missouri Sta. Res. Bul.* 343 (1942), pp. 10).—In a series of experiments lots of White Leghorn chicks receiving rations containing all the known vitamins required by the chick, sucrose and acid-washed and alcohol-extracted casein developed perosis and dermatitis in about 28 days, but they

were largely prevented by feeding 1γ of biotin per day per chick. Injecting intramuscularly or intraperitoneally 2γ-5γ of biotin were required to protect chicks on the raw egg white. The typical dermatitis developed in about 28 days with the perosis in 8-14 days. Several reasons were given to show that the raw egg white possessed a biotin-binding property which was destroyed by heat. It was concluded that biotin is the sole factor concerned in the prevention of dermatitis but an additional factor may be concerned in preventing perosis.

Gizzard erosion in growing chickens, D. MILLER and J. C. HAMMOND. (U. S. D. A.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 317-320).—In order to determine the effect of diets on gizzard erosion at hatching, day-old chicks were killed and scored by methods previously noted (E. S. R., 87, p. 561). The changes were noted in the groups after 7, 13, 28, and 35 days on diets some of which were treated with ethyl ether or supplemented with bile or fortified cod-liver oil. Gizzard erosion in 1-week-old chicks was not very severe regardless of the diet fed, but the gizzard factor which seemed to be labile was removed by treatment with ethyl ether or additions of 2 percent cod-liver oil. Additions of 1 percent desiccated bile reduced gizzard erosion to a very low level at 28 days of age.

Method for relief of crop impaction affecting poultry, G. R. SIPE and H. D. POLK (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 7, p. 7, figs. 2).—A method for relieving crop impaction by the use of water and a suitable device for introducing the water into the crop is proposed. It has been found successful on farms which do not have a water pressure device.

The nature of egg yolk discoloration produced by cottonseed meal, A. D. SWENSEN, E. A. FIEGER, and C. W. UFF. (La. State Univ.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 374-378).—Gossypol was found to be the factor in cottonseed meal responsible for the olive-colored yolks of stored eggs from hens fed cottonseed meal. In feeding experiments lots of two hens were supplied with supplements to a commercial ration of gossypol either in a capsule in wesson oil or in 30 percent cottonseed meal rations. All the eggs from these hens developed a characteristic chocolate color in an ammonia atmosphere and the usual olive-green color in storage, while yolk color was normal in eggs from hens on a standard ration. Normal fresh egg yolk and yolks from hens on a cottonseed meal ration allowed to stand overnight in an ammonia atmosphere developed the same brown color if gossypol were added; otherwise they remained normal. In chemical fraction of the yolk proteins it became evident that the protein decomposed during storage so that the iron was allowed to combine with gossypol and form the olive color. The presence of ferric chloride in the ration prevented the absorption of gossypol by the hens and formation of olive-green yolks on storage.

The effect of alfalfa leaf meal and dried cereal grass on egg production and hatchability, W. W. CRAVENS, C. E. HOLMES, J. G. HALPIN, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Poultry Sci.*, 21 (1942), No. 4, pp. 301-305, figs. 2).—Rations composed largely of grains and grain byproducts supplemented with minerals and proteins resulted in a deficiency in the hatchability of eggs produced in three experiments. The deficient factors were supplied by alfalfa leaf meal and to a lesser extent by dried cereal grass. The results were not greatly improved by supplementing the rations with riboflavin and manganese. The three experiments supplemented the studies of vitamin K in alfalfa meal and dried cereal grass previously noted (E. S. R., 85, p. 807). The studies were conducted with additions of 0.8 to 4 percent of these materials to basal rations in 10-20 White Leghorn pullets each from 5 to 6 mo. of age in different seasons. No significant difference in egg production was discovered. The pronounced

slump in hatchability occurring in the fall and early winter was prevented by 2 percent of alfalfa meal added to the ration, but no increase was produced in hatchability by additions of riboflavin.

Changes in the form of inositol during incubation of eggs, D. W. WOOLLEY (*Soc. Expt. Biol. and Med. Proc.*, 49 (1942), No. 4, pp. 540-541).—Studies of the free and total inositol content of eggs during incubation showed that the total content did not increase, but the proportion in the free form rose from 0.046 µg. per milligram in the fresh egg to 0.19 in the egg after 20 days' incubation.

Farm refrigeration preserves egg quality, R. J. EVANS and J. S. CAEVER. (Wash. Expt. Sta.). (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 6, pp. 341-344, fig. 1).—Determination of the albumen index of new laid eggs showed a temperature of 40° F. to be better for storage and in the preservation of quality than 56° F. There was also sweating of eggs held at lower temperatures. A decrease in the humidity at higher temperatures increased the evaporation and produced a larger air cell. The study was conducted with fresh collected eggs from 176 pullets and stored at 40°, 57°, and 76° F. with variation in the humidity and the storage conditions.

Egg-laying of ducks as an enforced relaxation oscillation, H. KALMUS (*Nature [London]*, 148 (1941), No. 3760, pp. 626-627, fig. 1).—Hens' eggs build up gradually the energy content but are expelled suddenly at a rather constant weight. On the other hand ducks may deposit eggs of variable size at rather constant intervals, sometimes daily, for months. Under such conditions there are gradual decreases in the egg size so that the last eggs of clutches are frequently considerably lighter than the first eggs of a clutch. In nature brooding gives opportunity to build up the size of the eggs in new clutches.

An observation on the feeding of cut grass to goslings, M. M. WEIGER (*Harper Adams Util. Poultry Jour.*, 27 (1942), No. 6, p. 117).—The provision of cut grass as a sole feed to two groups of four goslings was insufficient to promote normal growth, although earlier experiments² have demonstrated that on free range without supplementary feed goslings may make good growth.

The effect of temperature on the hatchability of turkey eggs, G. P. GOON-EAL (*North Dakota Sta. Bul.* 317 (1942), pp. 17, figs. 3).—Hatching results over a 6-yr. period with turkey eggs varying the temperature from 100° to 105° F. for the incubation period showed that in general the best hatching results were secured with temperatures of 102° in a still air incubator. The hatching was definitely lowered above this temperature and the time of hatching was delayed with lower temperatures. It is also noted that greater amounts of evaporation accompanied higher temperatures. It appeared that the incubation temperature for turkey eggs should be 1° lower than for chicken eggs. In a 3 yr. comparison of 98° and 99° in a forced draft incubator a higher hatchability was obtained at 99°

DAIRY FARMING—DAIRYING

The principles of dairying, H. F. JUDKINS, revised by M. J. MACK (*New York: John Wiley & Sons; London: Chapman & Hall*, 1941, 3. ed., rev., pp. XVII+315, pl. 1, figs. 92).—The third edition (E. S. R., 65, p. 865) of this well-known text is noted.

[Experiments in dairying in Arizona] (*Arizona Sta. Rpt.* 1941, pp. 50-54).—Studies for which results are presented include: Normal growth of dairy cattle, the yield and composition of barley and Sudan grass pastures, a comparison of alfalfa silage v. Atlas sorgo silage for dairy cows, the efficiency of

² Harper Adams Util. Poultry Jour., 26 (1941), No. 4, pp. 81-83.

various methods of cleaning milking machines, factors affecting the solids-not-fat content of milk, and a comparison of the Babcock test v. the Mojonnier test for determining the fat content of homogenized milk.

[**Dairy investigations in Florida**] (*Florida Sta. Rpt. 1941*, pp. 60, 62-63, 65, 70).—Studies, for which results are presented by R. B. Becker, P. T. D. Arnold, D. A. Sanders, L. L. Rusoff, T. R. Freeman, and E. L. Fouts, include the adequacy of the calcium and phosphorus supply in local dairy rations, the value of Napier grass as a pasture for dairy cows, the vitamin A content of milk as affected by varying levels of shark-liver oil in the ration, and the stability of milk toward oxidized flavor development and methods of storing frozen cream.

[**Dairy investigations in Kentucky**] (*Kentucky Sta. Rpt. 1941*, pp. 22-23, 26).—Results are noted on continuous v. rotational grazing of bluegrass pastures with dairy heifers and the merits of various criteria for determining the quality of farm cream.

[**Experiments with dairy cattle and dairy products in Massachusetts**] (*Massachusetts Sta. Bul. 388* (1942), pp. 18-19, 43-47).—Progress reports (E. S. R., 85, p. 809) presented herein include the influence of the level of manganese intake by cows on the manganese content of their milk (E. S. R., 86, p. 237) and a comparison of molasses-grass silage, phosphoric acid-grass silage, and corn silage, with particular reference to their influence on milk flavors, both by J. G. Archibald and C. H. Parsons; the use of urea as a partial substitute for protein in dairy cattle rations, by Archibald; studies on chocolate-flavored milk including the significance of tannic substances and theobromine in chocolate milk, the effect of cocoa on the vitamin C content of milk, and the effect of cocoa on the coagulation of milk, all by W. S. Mueller, and the effect of the Electropure method of pasteurization on chocolate milk, by Mueller and A. M. Shipley; the effectiveness of oat flour and cocoa flour in preventing oxidized flavor defect in milk, ice cream, and fruit sherbets, by Mueller and M. J. Mack; the use of corn sirup solids in ice creams and ices, by Mack and J. H. Nair (E. S. R., 86, p. 525); the value of new stabilizing materials for ice cream, by Mack and Shipley; factors affecting the appearance of melted ice cream, by Mack; a comparison of the electric flash method v. the conventional vat method of pasteurization, by Lipman, J. H. Frandsen, and H. G. Lindquist; and efficiency of the cream separator in standardizing milk, by Shipley and Frandsen.

Dairying in New York State vs. dairying in Cuba and Mexico, R. S. BREED (*Farm Res. [New York State Sta.], 8* (1942), No. 3, pp. 12-13, figs. 2).—A discussion of present-day dairying in Mexico and Cuba, based on observations by the author during a recent visit to these countries.

*[**Dairy cattle investigations in Wyoming**] (*Wyoming Sta. Rpt. 1941*, pp. 9-10, 29).—Results are briefly presented for studies by H. S. Willard on the value of steamed bonemeal, cottonseed meal, and molasses as supplements for native hay and dried beet pulp for growing heifers; the relative merits of native upland pasture and irrigated sweetclover pasture for heifers; the increase in milk production resulting from the feeding of grain during the prelactation period; closed barns v. open sheds for milking cows; and the use of skim milk powder and cottonseed meal as a substitute for skim milk in raising calves.

Feeding for milk production, I. R. JONES and R. W. MOESE (*Oregon Sta. Bul. 398* (1941), pp. 47, figs. 9).—A practical handbook on dairy cattle feeding.

The relation of grain feeding to milk production, A. A. BORLAND, A. L. BEAM, and P. D. JONES (*Pennsylvania Sta. Bul. 424* (1942), pp. [1]+10, figs. 2).—Based on a total of 66 yearly milk production records with Holstein and Brown Swiss cows fed, in addition to hay and silage, grain at levels ranging from 70 percent of the Haecker standard for milk production to an unlimited amount,

It is concluded that an increase in the grain allowance of cows up to the limit of their capacity will result in a marked increase in milk production, and under careful management was accompanied by no injurious results to the animals. The law of diminishing returns was found to operate with increasing allowances of grain, since increments of grain at the higher feeding levels gave continuously decreasing yields of milk per unit of grain, hence the feed cost of milk production gradually increased with increased allowances of grain. On the basis of prices of feed and milk prevailing in Pennsylvania in March 1942, feeding grain according to the Haecker standard for milk production gave the greatest returns over cost of feed. A reference table indicating the most profitable allowance of grain per cow with varying relationships between the price of milk and the price of grain is presented.

Measuring the yield of nutrients of experimental pastures: A comparison of the results obtained by grazing dairy cattle with those estimated from the yields of grass clipped from plots, R. E. HOBASON, J. C. KNOTT, V. L. MILLER, and F. B. WOLBERG. (Coop. West. Wash. Expt. Sta. and U. S. D. A.). (*Washington Sta. Bul. 411 (1942), pp. 31, fig. 1*).—Trials were conducted over five consecutive seasons comparing the estimated yield from pastures by clippings v. that secured by actual grazing with milking cows. Four or five separate tests were made each year. Uniform height clippings were made from 20 protected areas and 20 grazed areas at the end of each grazing period, with the difference in yield from the protected and grazed areas considered as the amount actually consumed. Chemical analyses and digestion trials on the clipped herbage were used as the basis for estimating the actual amount of digestible nutrients consumed. In the grazing trials, the nutrients secured from pasture were estimated by calculating the total nutritive requirements of the cows for maintenance, live weight change, and milk production and deducting from this the amount of nutrients supplied by supplementary feed. Over the 5 yr., the amount of nutrients from pasture as estimated from the clippings was 108.3, 90.9, 144.4, 132.8, and 154.4 percent, respectively (mean 127.0 percent), of those secured in the grazing trials. Conditions which may affect the accuracy of estimated yield by clipping are discussed.

It is concluded that the clipping of representative areas for the purpose of determining chemical composition and digestibility of the herbage is a desirable adjunct to pasture experiments with dairy cattle, but that yields can be accurately determined only by grazing tests.

The conservation of nutrients in grass silage, IV, J. A. NEWLANDER, H. B. ELLENBERGER, and C. H. JONES (*Vermont Sta. Bul. 485 (1942), pp. 11*).—Continuing this series of investigations (E. S. R., 83, p. 667), first and second cuttings of timothy and mixed grasses were ensiled in small wooden silos with 2 to 3 percent of molasses added as a preservative. The average total loss of dry matter in the four lots of silage was 24.2 percent, attributed in part to the small size of the silos. In all cases the edible silage was of good quality as judged by appearance, odor, palatability, and digestibility. The silages compared closely with early-cut hay in digestibility and in total digestible nutrient content. Hays cut in mid-July and in early August contained 48.6 and 23.2 percent as much digestible crude protein and 91.8 and 79.4 percent as much total digestible nutrient, respectively, as the early-cut hay. Practical suggestions are offered for ensiling grasses and legumes without the use of preservatives.

The digestibility by dairy cows of a grass silage, P. D. SEARS and F. B. SELL (*New Zeal. Jour. Sci. and Technol.*, 23 (1941), No. 1A, pp. 50A-56A).—Herbage from a highly fertile pasture was ensiled in a pit silo, with the addition of 30 lb. of molasses per ton of green material. Digestion experiments with four cows (two Jerseys and two Holsteins) gave the following coefficients of digestibility:

Dry matter 64.8, organic matter 68.4, crude protein 50.1, crude fiber 78.7, ether extract 73.8, and nitrogen-free extract 64.8. Breed, size, and level of production of the cows had no apparent effect on their digestive ability.

The relation of plane of nutrition to milk production and milk composition in New Zealand.—I, II, Effect of subnormal feeding, W. RIDDER, I. L. CAMPBELL, F. H. McDOWALL, and G. A. COX (*New Zeal. Jour. Sci. and Technol.*, 23 (1941), No. 2A, pp. 80A-98A, figs. 4; pp. 99A-112A, figs. 5).—The results of two series of trials are reported.

Three groups of cows all in early stages of lactation were fed over a 90-day experimental period as follows: (1) Continuously on a normal plane of nutrition, and (2) and (3) alternately fed a normal ration and a one-half-normal ration for 30-day periods under a double reversal plan. The changing of groups (2) and (3) from full to half rations caused a reduction in yield, although the decrease was less than expected. It had no consistent influence on the fat content of the milk, but caused a consistent decrease ranging from 0.3 to 0.5 percent in the solids-not-fat content and also an increase in the iodine number and saponification value of the fat. Both the solids-not-fat content and the characteristics of the butterfat returned to normal when full feeding was resumed.

The second series was essentially a duplication of the first except that the cows were in advanced stages of lactation. The results paralleled those for the first trial in all respects. It appeared that the seasonal decline in solids-not-fat in milk may be due to subnormal nutrition. This effect was not altered by the stage of lactation of the animal.

Carotene content of the blood plasma of dairy cattle in relation to vitamin A deficiency. W. D. GALLUP and A. H. KUHLMAN. (*Okla. Expt. Sta.*). (*Okla. Acad. Sci. Proc.*, 21 (1941), pp. 89-92).—Periodic determination of the plasma carotene level of groups of cows receiving prairie hay as their major source of carotene gave evidence that those on a full hay ration varied from 250 to 479 $\mu\text{g.}$ of carotene per 100 cc. of plasma, those on a 50-percent normal hay intake from 179 to 201 $\mu\text{g.}$, and those on a 25-percent normal level from 80 to 167 $\mu\text{g.}$ Cows whose plasma carotene during the last 90 days before calving averaged less than 150 $\mu\text{g.}$ per 100 cc. were generally in poor condition after calving, and many of the calves were weak and failed to survive. Apparently this level of plasma carotene indicates a border-line deficiency of vitamin A.

The effect of a high vitamin A intake on the blood and milk carotene of Holstein and Guernsey cows. H. J. DEUEL, Jr., L. F. HALLMAN, C. JOHNSTON, and F. MATTSO (*Jour. Nutr.*, 23 (1942), No. 6, pp. 567-579, fig. 1).—Continuing this investigation (E. S. R., 86, p. 522), the addition of shark-liver oil to the rations of Guernsey and Holstein cows at levels supplying from 700,000 to 4,200,000 International Units of vitamin A daily resulted in an increase in the vitamin A content of the milk at a rate of approximately 47 units per gram of butterfat for each 1,000,000 units fed. The maximum amount of vitamin A attained was 331 I. U. per gram of butterfat. The efficiency in secretion of ingested vitamin A was about 3 percent. The increase in vitamin A was accompanied by a decrease in milk carotene and a concomitant drop in blood carotene until 2,100,000 I. U. of vitamin A were ingested; but little drop in carotene occurred above this level. A proportionality was found to exist between the levels of carotene in the blood and in the milk. The slope of the curve was similar for Guernseys and Holsteins, although the latter breed was at a much lower level.

Milk yields and milking rates of the individual quarters of the dairy cow udder. C. A. MATTHEWS, W. W. SWETT, and R. R. GRAVES (*U. S. Dept. Agr., Tech. Bul.* 827 (1941), pp. 32, fig. 1).—Data obtained on the rate of milking and the amount of milk produced by individual quarters of 94 cows milked by

machine are summarized. On the average 29.2 percent of the total milk was yielded by the left rear quarter, 20.2 by the left front, 21.6 by the right front, and 29.0 by the right rear quarter. Among this number 21.3 percent of the left and 28.7 percent of the right front quarters yielded over 25 percent of the total, while 26.6 percent of the left rear and 25.5 percent of the right rear quarters yielded less than 25 percent of the total. The relative milk yields from the separate quarters of individual cows varied little from day to day or from morning milkings with higher yields to evening milkings with lower yields, but there was some variation in this respect from the third to the sixth month of lactation and a greater change from one lactation to another. The average total milking time was 8.28 min., of which 1.42 min. was devoted to massaging the udder at the end of milking which took the place of stripping. At 2.5, 5.0, and 7.5 min. after the start of milking 49.9, 81.1, and 92.8 percent of the total yield from the front quarters and 43.1, 76.2, and 91.2 percent of the total yield from the rear quarters had been obtained. Variations in the rate of milking were greater between cows than between individual quarters of the same udder. As milk production declined with advance of lactation, the decrease in milking rate was nearly in the same proportion as the decrease in yields. Many other interesting relationships are discussed.

Machine milking put on a time schedule, A. C. DAHLBERG (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, p. 6).—A résumé of research previously noted (*E. S. R.*, 85, p. 393).

Artificial induction of lactation in virgin animals, S. J. FOLLEY and F. G. YOUNG (*Nature [London]*, 148 (1941), No. 3758, pp. 563-564, fig. 1).—Two virgin goats which previously had been brought into artificial lactation by the application of diethylstilboestrol ointment to the udder were again stimulated to secrete milk by applying to the udder three times weekly 1 gm. of 1-percent diethylstilboestrol ointment. After milk secretion by this method had reached its peak, subcutaneous injection on alternate days of 5 cc. of an alkaline extract of ox anterior pituitary stimulated further secretion, the total yield reaching 870 cc. per day in one case and 1,700 cc. in the other. Analyses showed that the milk secreted by both goats was normal in composition. It appeared that under suitable conditions artificial lactation so evoked may approach that normally following parturition.

Growth of the male guinea pig mammary gland with diethylstilbestrol, A. A. LEWIS and C. W. TURNER. (Mo. Expt. Sta.). (*Endocrinology*, 30 (1942), No. 4, pp. 585-590, figs. 10).—Normal male guinea pigs were injected daily subcutaneously with diethylstilboestrol (dissolved in oil) at seven levels ranging from 0.01 to 50 μ g. per day over a period of 20 days. At levels of 0.1 μ g. or above, some extension of the mammary gland occurred, with lobule development being observed in all cases showing duct extension. However, no obvious signs of main duct growth were apparent. The teats of all animals receiving 0.1 μ g. or more were larger than those of the controls.

Rôle of estrogen in the stimulation of mammary-lobule-alveolar growth by progesterone and by the mammogenic lobule-alveolar growth factor of the anterior pituitary, J. P. MIXNER and C. W. TURNER. (Mo. Expt. Sta.). (*Endocrinology*, 30 (1942), No. 4, pp. 591-597).—Employing the assay technic previously described (*E. S. R.*, 86, p. 671), progesterone and oestrone were administered simultaneously at various levels. While the range in the amount of oestrone which would best synergize with 1 mg. of progesterone in stimulating mammary lobule-alveolar growth was quite wide, approximately 100 International Units of oestrone were optimal. When progesterone was injected alone approximately six times as much was required to secure the same degree of alveolar growth as when oestrone was simultaneously injected. Similarly,

oestrone enhanced the ability of pituitary materials in stimulating such alveolar growth. Oestradiol benzoate or diethylstilboestrol could be substituted for oestrone as a synergist with progesterone in stimulating lobule-alveolar growth.

A controlled attempt to restore fertility in dairy cattle by treatment with gonadic and gonadotropic hormones. S. A. ASDELL, M. G. FINCHER, S. E. SMITH, and F. I. ELLIOTT ([*New York*] *Cornell Sta. Mem.* 243 (1942), pp. 27).—As experimental subjects in this extensive study, 47 cows with a history of difficult breeding or infertility were assembled and divided into two comparable groups. The cows in the experimental group were injected with from 20,000 to 30,000 rat units of oestrogen, and when conception did not follow anterior pituitary extract was then injected. In the control group 50 percent of the cows conceived and delivered calves, as against 43 percent in the experimental group. There was no apparent relationship between age and percentage of conception. In a search for changes in the blood which might be associated with sterility, hemoglobin, glucose, calcium, inorganic phosphorus, lipid phosphorus, and cholesterol in the blood of sterile cows were found to be within the normal range of variation. Acidity of the vagina was encountered in only one case, suggesting that this condition is seldom the cause of sterility.

Supplementing the controlled experiments, field trials were carried on in two commercial herds. In one, which had been under close veterinary supervision, 17 sterile cows were treated with gonadic or gonadotropic hormones, of which 29.4 percent conceived. In the other herd, which had been under less close supervision, 17 animals were similarly treated, of which 88.2 percent conceived, but abortions reduced the calf crop to 58.8 percent of the cows treated. The high spontaneous recovery in the control group emphasizes the need for exact care in the planning and interpretation of experiments conducted to test methods for the restoration of fertility which has become impaired.

List of sires proved in dairy herd improvement association, 1942 (*U. S. Dept. Agr., Misc. Pub.* 487 (1942), pp. 143).—This publication, the sixth of the series (*U. S. R.*, 86, p. 235), contains the names and summarized records of 1,850 sires whose records were tabulated between April 1, 1941, and January 1, 1942.

Electrocardiograph studies in normal dairy cattle. B. V. ALFREDSON and J. F. SYKES. (*Mich. Expt. Sta.*). (*Jour. Agr. Res. [U. S.]*, 65 (1942), No. 2, pp. 11–37, figs. 5).—Using the Hindle No. 2 model of the Einthoven electrocardiograph with three standard leads, three serial electrocardiograms, taken about 1 mo. apart, were obtained on 97 normal dairy cattle ranging in age from 5 mo. to 12 yr. The heart rate for all individuals averaged 71.6 beats per minute. For those under 1.5 yr. of age the average rate was 82.5, and for those over 1.5 yr. 67.8. The waves in heart beats are expressed in the P, Q, R, S, T form commonly used for human subjects. The form and occurrence of the various deflections are discussed. The duration of the PR interval ranged from 0.10 to 0.30 sec., averaging 0.19; the QRS interval averaged 0.09 sec., and the QT interval 0.39 sec. The duration of QT and, to a lesser extent, of PR was inversely proportional to heart rate. The interval length for the bovine was quite similar to that of the human beings, but in all other respects there was little resemblance between the two. Variations in interval length and in the form and potential of the various deflections occurred much more frequently in the bovine than in the human electrocardiogram, which renders it of doubtful value for diagnostic purposes.

The microflora of milk drawn aseptically from Utah cows. L. W. JONES and K. R. STEVENS. (*Utah State Agr. Col.*). (*Utah Acad. Sci., Arts, and Letters, Proc.*, 18 (1941), p. 9).—Milk obtained from each quarter of the udder of 10 cows over a 4-mo. period was found to contain an average of 239 bacteria per cubic centimeter, with a range of from 49 to 511. The number of bacteria

in milk from an individual cow was quite consistent from day to day. It is concluded that the udder contamination from healthy cows is a negligible factor in producing milk of low bacterial count. Approximately two-thirds of the organisms appearing on the plates were cocci and one-third rods, which finding corresponds closely with results obtained in other sections of the country.

The bacterial content of goat milk, C. S. BRYAN. (Mich. Expt. Sta.). (*Amer. Jour. Vet. Res.*, 3 (1942), No. 6, pp. 92-95).—Of 380 goats in 15 herds which were examined 2.3 percent had streptococcal mastitis, 1.3 percent staphylococcal mastitis, and 0.5 percent noninfectious mastitis. Of the noninfected animals, 97.5 percent gave milk of class 1 methylene blue quality and 94 percent of class 1 resazurin quality, while only 4 percent gave milk containing over 1,000 bacteria per cubic centimeter.

Fluorescent bacteria in dairy products, E. R. GARRISON and B. W. HAMMER. (Iowa Expt. Sta.). (*Iowa State Col. Jour. Sci.*, 16 (1942), No. 3, pp. 363-377).—Employing various enrichment procedures as described, cultures of fluorescent bacteria were isolated from samples of milk, cream, ice cream, butter, water, feed, soil, and manure, indicating a wide distribution. All cultures studied (496) were Gram-negative, non-spore-forming rods with polar flagellation, which grew well on common media and were psychrophilic. They could be divided into six different classes based on changes produced in litmus milk at 21° C. Many were capable of proteolysis and lipolysis, resulting in flavor defects in milk and butter. Of 52 selected cultures which were inoculated into butters, 90.4 percent produced flavor defects in uncultured, unsalted butter held for 7 days at 21°; 69.2 percent in cultured, unsalted butter; and 48.1 percent in cultured, salted butter. Putrid and rancid flavors were especially common among the off-flavors produced. Of 113 samples of fresh sweet-cream butter examined, about one-third yielded fluorescent bacteria. Off-flavor development was more prevalent in butters containing such organisms than in those free from them.

Mastitis and the plate count of milk.—II, The influence of *Streptococcus agalactiae* mastitis upon the standard plate count of milk, M. E. MORGAN, E. O. ANDERSON, and W. N. PLASTRIDGE. (Univ. Conn.) (*Jour. Milk Technol.*, 5 (1942), No. 2, pp. 67-76, fig. 1).—Continuing this series (E. S. R., 87, p. 106), composite samples of milk were taken from each of 93 dairy herds, all of which were known to have harbored animals affected with *S. agalactiae* mastitis prior to the time of this study. These were plated in 3 dilutions on old and new standard medium and on Edwards medium. Total colony counts on new standard medium ranged from 1,270 to 4,330,000 per cubic centimeter. Seventy-eight of the 93 gave β -hemolytic *S. agalactiae* counts on Edwards medium, with a range from 7 to 217,000 per cubic centimeter. The contribution of *S. agalactiae* to the total number ranged from 0 to 48.03 percent. For each 1-percent increase in the incidence of infected quarters in these herds, there was an increase of 58.85 ± 8.05 in *S. agalactiae* count. There was no correlation between total counts and the number of *S. agalactiae* present. Apparently *S. agalactiae* mastitis may be responsible for a large proportion of the standard plate count on low count milk, but will contribute only a very small percentage of the total number of bacteria in high count milk.

Study of a ropy milk organism, L. Ó. DROMA and M. GRIMES ([*Irish Free State*] *Dept. Agr. Jour.*, 38 (1941), No. 1, pp. 68-73).—This study identified *Micrococcus pituitoparus* as the primary cause of ropy fermentation of milk. Morphological, cultural, and biochemical characteristics of the organism are described, and methods for its control and elimination are suggested.

Cryophilic bacteria as a cause of milk samples failing the methylene blue test, C. S. MORRIS (*Dairy Indus.*, 7 (1942), No. 3, pp. 63-64, 69).—Numerous samples of milk were encountered in which bacterial number increased practically

as rapidly at an incubation temperature of 4° C. as at atmospheric temperature. Milk when held overnight at low temperature generally had a high colony count and a short methylene blue reduction time. Isolated cultures of the cryophilic bacteria proved to be of the pseudomonas types. Checks on farms producing such milk indicated that water supplies were the chief source of contamination, and that such trouble could be controlled by thorough sterilization of milk cans and dairy utensils.

The bacterial population of paper milk containers in relation to methods of moisture proofing. J. W. RICE (*New York State Sta. Tech. Bul.* 263 (1942), pp. 29, pls. 4, fig. 1).—Experimental lots of square-type paper milk containers, fabricated in the usual manner, were waxed with paraffins having melting points of 123°–125°, 125°–127°, 128°–130°, and 133°–135° F., each used at waxing bath temperatures of 150°, 160°, 170°, and 185°. The containers were then packed in cartons of 100 each, and these were sealed for transportation and delivered to the laboratory. Broth sterility tests on one-half of the containers from each run showed approximately 80 percent of them to be sterile, with no significant difference in the percentage of sterility among the several sets. The plating of sterile water rinses from representative containers of each set revealed approximately 60 percent sterility, again with no significant difference between sets. Only a few containers yielded more than five colonies per container. Most effective moisture proofing, as indicated by the degree of penetration of methylene blue dye into the walls, corners, and seams of the container, was obtained by treating the paper with wax of a melting point of 133°–135° applied at 150°.

Public health compliance by manufacture of paper for packing perishable foods. J. R. SANBORN. (N. Y. State Expt. Sta.). (*Jour. Milk Technol.*, 5 (1942), No. 2, pp. 88–93).—Based on numerous bacteriological analyses of paper-board materials at various stages in the manufacturing process and on the finished product, it is the author's opinion that the manufacturers in general are complying with public health requirements. Substantiating data are presented.

Development of oxidized flavor and the speed of oxidation of ascorbic acid in milk. G. H. HARTMAN and O. F. GARRETT. (N. J. Expt. Stas.). (*Jour. Milk Technol.*, 5 (1942), No. 2, pp. 86–87).—Data are presented on seven samples of milk examined while fresh and after 24, 48, and 72 hours' storage. One sample, which passed through a worn bronze pump, developed pronounced oxidized flavor and was relatively very low in ascorbic acid content at the end of 72 hr. Among the other six, which were similarly handled except that they were passed through a stainless steel pump, the three which developed slight oxidized flavor were lower in ascorbic acid content than the remaining three which showed no trace of this flavor.

How methods and promptness of cooling affects the quality of milk, with suggestions for producing high quality milk. A. J. GELPI, C. S. McCLESKEY, and D. M. SEATH (*Louisiana Sta. Bul.* 344 (1942), pp. 15, figs. 4).—Comparing various methods of milk cooling, it was found that milk cooled in cans from 33° to 40° F. by submergence in agitated cooling medium contained more bacteria than milk chilled to a comparable temperature by passing it over tubular or conical coolers. A delay of 2 hr. in cooling did not materially affect the quality of milk rapidly chilled over surface coolers during a subsequent holding period of 12 hr. at 40°. A similar delay for milk cooled in cans resulted in a significant increase in bacterial count during such a holding period. The method of cooling did not appreciably affect milk flavor. A practical procedure for producing high-quality milk is outlined.

"Smothered" milk. G. M. TROUT, C. S. BRYAN, and R. E. HOWWOOD (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 342–353).—Milk produced under sanitary

conditions from individual cows failed to show a smothered flavor when cooled at once in clean cans either tightly covered or uncovered or when cooled after standing for 1 hr. in a tightly closed container. The flavor score varied more between individual cows than as a result of the method of cooling. The odor of milk in old milk-stoned cans was predominantly old, musty, or stale, due to the condition of the can, but these odors could not be discerned in the milks when samples taken in glass from such cans were scored separately. No significant difference in bacterial count was obtained in milk cooled in new cans or in old milk-stoned cans when sampled fresh or after overnight storage in the cans at 40° F. when all the cans were sanitized by a rotary washer and wet-steam sterilizer. It is concluded that "milk sanitarily produced in a well-ventilated stable from healthy cows under proper feeding management may be safely cooled in a closed container without resulting in the so-called smothered flavor."

Formalin adulteration in milk and its detection in the resulting butter, G. T. PYNE and J. LYONS (*Irish Free State*] *Dept. Agr. Jour.*, 38 (1941), No. 1, pp. 74-76).—Attempts were made to detect the presence of formaldehyde in butter churned from creams which contained from 2 to 50 p. p. m. of this compound by means of the Shrewsbury-Knapp test. Butter initially containing 2 p. p. m. of formaldehyde failed to give a positive reaction for its presence after from 3 to 4 days of storage, while an initial content of 5 p. p. m. was detectable after 3 months' and 15 p. p. m. after 6 months' storage.

Reducing the loss of fat during churning, G. H. WILSTER, R. P. ROBICHAUX, R. E. STOUT, and R. W. STEIN (*Oregon Sta. Bul.* 397 (1941), pp. 36).—This study covered the fat losses in the buttermilk from the churning of 2,141 lots of cream. Determining the percentage of total fat churned lost in the buttermilk was found to be the only practical way of comparing the fat losses. The Babcock-butyl alcohol test, as described, proved satisfactory for this purpose. In a large number of churnings of vat-pasteurized cream, fat losses in the buttermilk ranged from 0.44 to 3.2 percent, with weighted averages in four series amounting to 0.92, 1.06, 1.16, and 1.22 percent, respectively. One series of churnings from flash-pasteurized cream showed an average loss of 1.32 percent. Fat losses in buttermilk tended to be higher in summer than in winter, in the churning of low-fat cream than in high-fat cream, and in churning at relatively high than at low temperatures. The exclusion of rinse water from the cream churned also tended to reduce fat lost in the buttermilk. In churning vacuum-pasteurized cream fat losses in the buttermilk ranged from 1.12 to 1.64 percent. Quick cooling of the cream from the Vacreator to at least 50° F. and a final lowering to 40°-45° proved very important in maintaining low fat losses in vacuum-pastuerized cream.

Diacetyl and acetylmethylcarbinol production in the manufacture of unsalted butter, T. I. HEDRICK and B. W. HAMMER (*Iowa Sta. Res. Bul.* 301 (1942), pp. 825-860).—In a series of trials with sweet and neutralized sour creams, both under laboratory and semicommercial conditions, it was found that increasing the acidity, adding small amounts of citric acid to the cream, and agitation of the cream during ripening, all tended to increase both the diacetyl and acetylmethylcarbinol content of the cream. In general, as the diacetyl content increased during ripening acetylmethylcarbinol also increased, although the relationship between them was somewhat variable. The ratio of diacetyl in the cream to that in the resulting butter averaged 1:0.352 (1:0.142 to 1:0.709) and of acetylmethylcarbinol 1:0.217 (1:0.059 to 1:0.683). In comparing the influence of various holding temperatures for unsalted butter on the development of diacetyl and acetylmethylcarbinol in the butter, increases were generally greater

in butter held 3 days at 60° F. plus 4 days at 36°–40° than in that held 1 week at 36°–40°. While both increases and decreases in the content of these compounds in butter were experienced under all holding conditions, the increases were more numerous than the decreases.

A study of the quality of retail butter in Michigan, I. A. GOULD (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 298–304).—Examination of 153 samples of butter obtained at random in retail stores in four different markets revealed about one-half as poor in flavor, one-third poor in extraneous matter, two-thirds poor in yeast and mold count, one-sixth poor in mold mycella, and about two-fifths poor in composition. No definite relationship could be established between flavor and price or between claims on the package as to quality and the flavor. These findings are held to indicate the desirability of establishing a butter-grading system as a means of protecting the consumer, since at present the consumer has no reliable means of ascertaining the quality of butter which is available for purchase.

The manufacture of Cornhusker cheese, E. L. REICHART and P. A. DOWNS (*Nebraska Sta. Bul.* 342 (1942), pp. 13, figs. 13).—The cheese described is somewhat softer in texture and milder in flavor than typical American Cheddar. The method of manufacture, which is described in detail, differs in only a few respects from that employed in Cheddar cheese manufacture and requires essentially the same equipment. The cheese is produced in 5-lb. hoops and is waxed before ripening. Satisfactory ripening may be obtained in 30–60 days at a temperature of 65° F. and a relative humidity of 70–80. At 45° the curing period will vary from 6 to 12 mo. The cured cheese may be held at 32° up to 18 mo. with little change in flavor or texture.

Improved practices aid cheese makers, J. C. MARQUARDT. (N. Y. State Expt. Sta.). (*Food Indus.*, 14 (1942), No. 6, pp. 49–50, fig. 1).—Suggestions are offered on the effective use of chlorine as a sterilizing agent and deodorizer, methods of fly control, precautions for controlling mold in the cheese rooms, and the salt control in cheese.

The progress and present position of research on cheese starters in New Zealand, H. R. WHITEHEAD and G. J. E. HUNTER (*New Zeal. Jour. Sci. and Technol.*, 23 (1941), No. 1A, pp. 40A–46A).—A concise review, tracing research leading up to the finding that infection with air-borne bacteriophage is the main cause of failures of starter cultures (E. S. R., 85, p. 813).

A neglected phase of frozen desserts sanitation, F. W. FABIAN. (Mich. State Col.). (*Jour. Milk Technol.*, 5 (1942), No. 2, pp. 106–110).—A discussion of the role of unpasteurized products, such as flavoring, fruits, and nuts, in ice cream sanitation, with 16 references to the literature.

How to calculate gallon weights of dairy products, A. J. HAHN and P. H. TRACY. (Univ. Ill.). (*Food Indus.*, 14 (1942), No. 6, p. 55).—Simple and accurate methods are presented for computing the weight per gallon of ice cream mixes, condensed milk, and other products.

VETERINARY MEDICINE

Index-catalogue of medical and veterinary zoology.—Part 6, Authors: G to Gyser, A. HASSALL, M. A. DOSS, R. M. TAYLOR, G. B. CARLSON, and D. B. SEGAL (*U. S. Dept. Agr.*, 1942, pp. [1]+1459–1754).—A continuation of this index catalogue (E. S. R., 86, p. 526).

[Work in animal pathology and parasitology by the Arizona Station] (*Arizona Sta. Rpt.* 1941, pp. 44–45).—Report (E. S. R., 85, p. 664) is made of the outbreak of and control work with the stomach worm *Ostertagia ostertagi*,

analysis of a toxic range plant *Monolepis nuttalliana*, and treatment of range cattle for warbles.

[**Work in animal pathology by the Florida Station**] (*Florida Sta. Rpt. 1941*, pp. 58, 61-62, 67, 69).—Brief reports of progress (E. S. R., 85, p. 665) by M. W. Emmel, D. A. Sanders, E. West, and J. T. Creighton include the etiology of fowl paralysis, leukemia, and allied conditions in animals; a study of plants poisonous to livestock in Florida; the influence of sulfur on the body populations of lice in chickens; infectious bovine mastitis; and the diagnosis of (1) "wet wings," a new disease of chickens, and (2) "sod disease," an affection involving the feet of chickens, as due to a fungus infection.

[**Work in animal pathology by the Kentucky Station**] (*Kentucky Sta. Rpt. 1941*, pp. 27-29).—The work of the year (E. S. R., 85, p. 815) reported upon relates to virus abortion of mares, periodic ophthalmia, incoordination in young horses, corynebacteria in domestic animals, and paratyphoid bacilli.

[**Work in animal pathology and parasitology by the Wyoming Station**] (*Wyoming Sta. Rpt. 1941*, pp. 16-20, 22-25, 27-28).—The work of the year (E. S. R., 85, p. 105) reported upon covers soil nitrogen as related to abnormally poisonous properties of forage plants (E. S. R., 84, p. 101), poisoning from *Senecio*, selenium and other minerals which produce poisoning in livestock, feeding tests with *Parmelia molliuscula* (by W. T. Huffman) (coop. U. S. D. A.), calf diphtheria, abortion in ewes (by A. M. Lee), fowl paralysis, and the relation between the parasites of game animals and those of domestic animals (by R. Honess and J. W. Scott).

[**Contributions on animal pathology**] (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 16 (1941), No. 1-2, pp. 9-66, 115-166, 315-328, figs. 27).—Among the contributions presented (E. S. R., 86, p. 382) are the following: The Transmission of Tick-Bite Fever by the [Brown] Dog Tick (*Rhipicephalus sanguineus* Labr.), by W. O. Neitz, R. A. Alexander, and J. H. Mason (pp. 9-17); Studies on the Neurotropic Virus of Horsesickness—VII, Transmitted Immunity, by R. A. Alexander and J. H. Mason (pp. 19-32) (E. S. R., 81, p. 570); The Particle Size of African Horsesickness Virus as Determined by Ultrafiltration and Ultracentrifugation (pp. 33-50) and The Electrophoresis of the Neurotropic Virus of Horsesickness and Its Neutralizing Antibodies in Low Concentration (pp. 51-66), both by A. L. Polson; Description of a Tick, *Rhipicephalus glabroscutatum* sp. nov. (Ixodidae), From the Karroo Areas of the Union of South Africa, by R. du Toit (pp. 115-118); Recent Investigations Into the Toxicity of Known and Unknown Poisonous Plants in the Union of South Africa, XI, by D. G. Steyn and S. J. van der Walt (pp. 121-147) (E. S. R., 86, p. 382); South African *Senecio* Alkaloids—V, Notes on Isatidine, Rosmarinine, and Pterophine and On the Structure of Their Nectines and Nectic Acids, by H. L. de Waal (pp. 149-166); and A Note on the Influence of a Bloodmeal Ration on Porphyrin Excretion in Normal Bovines, by G. C. S. Roets (pp. 315-328).

Some mites injurious to domestic animals and man encountered recently by New York State veterinarians, D. W. BAKER (*Cornell Vet.*, 32 (1942), No. 3, pp. 326-333, figs. 14).—Notes are presented on chorioptic mange of the horse, psoroptic mange (scabies) of the cow, and acariasis (*Liponyssus* spp.) of the fowl, dog, and man.

Urinary calculi, problem in feedlot meat production, largely caused by ration, F. CROSS (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 3, pp. 16-17).—Attention is called in this brief practical account to the finding by the Colorado and other stations that a ration deficient in vitamin A will produce the urinary calculi found in livestock. An unbalance of minerals in the diet, thus result-

ing in an abnormal excretion of minerals by the kidney, is no doubt often the cause. Animals that are prevented from consuming, or fail to consume, the usual amount of water over a considerable period of time may excrete a concentrated urine and as a result calculi may form. The ration should in all instances have an ample supply of vitamin A, which is abundant in most green feeds and particularly in bright alfalfa hay, also minerals in amounts sufficient to meet the body requirements.

Milk sickness caused by white snakeroot, E. L. MOSELEY (*Bowling Green: Ohio Acad. Sci. and Author*, 1941, pp. IV+171, [pls. 3]).

Equine encephalomyelitis (western type) in humans in Alberta, 1941, A. C. MCGUGAN (*Canad. Pub. Health Jour.*, 33 (1942), No. 4, pp. 148-151).—An epidemic of equine encephalomyelitis occurred among horses and humans in Alberta during the summer and early fall of 1941, 42 cases having been reported among humans. Blood specimens from 28 of these were received for examination, of which 20 were positive and 8 negative.

Trichinella spiralis.—I, Incidence of infection in man, dogs, and cats in the New Orleans area as determined in postmortem examinations, W. SAWITZ (*Arch. Pathol.*, 28 (1939), No. 1, pp. 11-21, figs. 2).—A survey made in the New Orleans area of the occurrence of trichinosis in man, dogs, and cats is reported upon in this first contribution. The examination of human diaphragms and pectoral muscles obtained in 400 routine unselected necropsies disclosed 24 cases of infection with *T. spiralis* in that area, an incidence of 6 percent. The incidence of infections with this parasite in 300 dogs of this area was found to be 1.3 percent and the incidence in 90 cats to be 10 percent. The incidence in cats is considered to serve as an indicator of the endemicity of *Trichinella* infection in an area.

Trichinella spiralis.—II, Incidence of infection in hogs and rats in the New Orleans area, C. E. PERES (*Jour. Parasitol.*, 28 (1942), No. 3, pp. 223-226).—In continuation of the study above noted, the diaphragms of 516 southern hogs and the loins of 399 midwestern hogs were examined for *Trichinella* infection by the artificial digestion technic. None was found infected, neither was any of 50 samples of sausage from local butchers. Two positives, or 0.4 percent, were detected in 467 rats trapped in the New Orleans area.

[Studies of gramicidin and tyrocidine] (*Jour. Biol. Chem.*, 141 (1941), No. 1, pp. 171-206, figs. 3).—The chemical nature of gramicidin and tyrocidine is reported upon by R. D. Hotchkiss (pp. 171-185), the composition of gramicidin and tyrocidine by H. N. Christensen, R. R. Edwards, and H. D. Piersma (pp. 187-195), and some properties of gramicidin by M. Tishler, J. L. Stokes, N. R. Trenner, and J. B. Conn (pp. 197-206).

Phenothiazine as an anthelmintic, C. E. HOWELL and J. W. BRITTON. (Univ. Calif.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 255-265).—The findings here reported present several new facts concerning dosage, mode of administration, and toxicity of phenothiazine for horses. The work is summarized as follows: "(1) The efficiency of phenothiazine against the horse strongyles is amply confirmed. (2) Under southern California conditions treatment appears to be necessary in the early spring and late summer. (3) It is unwise to worm foals under 9 mo. of age unless *Trichostrongylus axei* is present. (4) The dose rate of phenothiazine is tentatively set at from 25 to 30 gm. per 1,000 lb. (5) Small repeated daily doses (1 to 5 gm.) of phenothiazine, given until the therapeutic dose is reached, are efficient and when given with a tonic are probably less dangerous than single large doses. (6) Brood mares up to the last month of pregnancy and lactating mares have been wormed with no ill effects. (7) An analysis of reported symptoms and autopsies of 650 horses receiving pheno-

thiazine indicates constipation, anemia, and congestion of the kidneys as effects of phenothiazine on horses. The anemia is mild, transient, and recovery is spontaneous. (8) Extreme anemia and emaciation and severe constipation are the only two known contraindications. (9) The source of the drug has little if any effect on its toxicity."

The authors have treated colts with rickets, mares in late pregnancy, mares suckling foals, and moderately anemic horses with no ill effects.

Inhibiting effect of various compounds on curative action of sulfanilamide and sulfapyridine in infected mice, G. W. RAIZISS, M. SEVERAC, and J. C. MOETSCH (*Jour. Amer. Pharm. Assoc.* 31 (1942), No. 7, pp. 198-200, figs. 2).—It was found that the therapeutic effect of sulfapyridine by mouth on mice infected with pneumococcus type II or *Streptococcus hemolyticus* was completely annihilated when *p*-aminobenzoic acid was administered simultaneously. The isomeric *o*-aminobenzoic acid proved to be much less inhibiting. The replacement of the amino group by the hydroxyl, the carboxylic acid by the sulfonic acid group, and the introduction of a third substituent into *p*-aminobenzoic acid resulted in a substantial destruction of the inhibitory effect. Nicotinic acid, cevitic acid, and even to a lesser degree thiamin chloride have only a slight inhibitory effect on sulfapyridine.

A study of drugs affecting the motility of the bovine rumen, R. W. DOUGHERTY. (Oreg. Expt. Sta.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 269-280, figs. 4).—Description is given of a method for recording variations of pressure in the rumen. The action of certain drugs on rumen motility is described.

The udder infusion treatments in a herd program for the control of streptococcal mastitis, C. S. BRYAN and H. H. RUHLAND (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 290-291).—It is pointed out in this practical account that the udder infusion treatments for mastitis involving the use of tyrothricin (gramicidin), novoxil, and acriflavine were reported during the last year to yield recoveries in from 80 to more than 90 percent of the infected cows treated. The recovery is measured by the freedom of the udder from mastitis streptococci. A brief summary is given of the several pertinent facts which the dairyman must understand before the treatment of any cow is commenced in order to insure success of the mastitis control program.

Biopsy of the bovine mammary gland in connection with mastitis studies, W. G. ANDBERG and A. G. KARLSON. (Minn. Expt. Sta.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 237-240, figs. 2).—Description is given of a simple technic for the biopsy of lactating mammary glands by the use of a sharp-edged cork borer. Sulfanilamide was applied locally in the incision to combat possible infection. Very little tissue damage followed, and there was no apparent diminution of the milk production as a result of these biopsies. This technic makes it possible to follow the progress of experimental work without sacrificing the animal.

The changes produced by *Brucella abortus* in the milk and udder of cows infected with Bang's disease, M. S. HOFSTAD (*Cornell Vet.*, 32 (1942), No. 3, pp. 289-294, figs. 4).—This contribution includes a description of the procedure and methods used in the study and the changes produced in the milk and in the udder.

Studies on cowpox.—II, A note on the longevity of vaccinia immunity in cattle, L. E. BOLEY and R. GRAHAM. (Univ. Ill.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 335-336).—Reporting further (E. S. R., 86, p. 580), in a herd of dairy cattle that presented many cases of natural cowpox over a period of years artificial immunity against vaccinia endured for at least 2 yr. in one group of 18 mature cows.

Sporadic bovine encephalomyelitis, I. B. BOUGHTON (*Abstr. in Texas Sta. Cir.* 96 (1942), pp. 20-21).—Reference is made to observations of several cases of a subacute disease of bovines, recorded by McNutt and Waller (*E. S. R.*, 84, p. 528) under the name of sporadic bovine encephalomyelitis as occurring in cattle in Iowa. It is thought to be due to a virus, but the manner of transmission is not known. It occurs during all seasons of the year, and yearly recurrence on the same premises is not the rule. Usually only a few calves in a herd are affected.

Sulfaguanidine in "white scours" of calves, G. H. WISE and G. W. ANDERSON. (*S. C. Expt. Sta.*) (*Jour. Amer. Vet. Med. Assoc.*, 100 (1942), No. 779, p. 160).—Brief report is made of five cases of white scours which recovered as the result of the administration of several doses of sulfaguanidine in aqueous suspension. Two of these cases had received "anti-coli-enteritidis-pasteurella serum" of bovine origin, but this failed to prevent the disease. Chemotherapy in all cases was initiated immediately after the first positive symptoms of white scours were manifested. The dosage per 100 lb. of body weight was reduced from 5 gm. as the initial dose to 3.5 gm. 4 hr. later, 2.5 gm. following an interval of 6 hr., and 2.5 gm. subsequently. The treatment was continued until the diarrhea definitely subsided, which was usually a short time after giving the third dose. However, in one case only one dose was necessary, whereas in another four doses were required. The treated calves remained weak and without appetite for about 2 days following cessation of the diarrhea. In order to provide nourishment to two of the calves during the recuperative period it was necessary to drench them with milk drawn from their respective dams. Within 3 days following the sulfaguanidine treatment no abnormal clinical symptoms were evident. A male calf that had recovered was sacrificed for autopsy, which revealed a slight catarrhal condition of the colon and a small hemorrhagic area in the fundus of the abomasum. Neither of these conditions was considered pathologically serious.

Treatment and prevention of scours—sulfaguanidine, succinyl sulfathiazole, G. H. WISE. (*S. C. Expt. Sta.*) (*Jersey Bul.*, 61 (1942), No. 27, pp. 1012-1013, 1030-1031, fig. 1).—Reporting further (see above) on the control of white scours, it is pointed out that sulfaguanidine is convenient and effective in its treatment. Preliminary observations on the use of succinyl sulfathiazole indicate that this more recently prepared chemical is also an excellent medicament for the treatment of this affection.

On additional antigens in the erythrocytes of cattle, L. C. FERGUSON, C. STORMONT, and M. R. IRWIN. (*Wis. Expt. Sta. coop. U. S. D. A.*) (*Jour. Immunol.*, 44 (1942), No. 2, pp. 147-164).—The authors have detected 30 antigens in the erythrocytes of cattle by means of isoimmune serums produced by transfusing blood from one individual into another or by immunizations of rabbits with bovine cells, or by both methods. Each cellular character appears to be produced by a single gene, although some may be products of linked genes. Since these antigens are passed only directly from parent to offspring, these characters may be used for exclusion in cases of disputed parentage in cattle.

Studies of pathology in cattle produced by liver fluke (*Fasciola hepatica*), D. R. MORRILL and J. N. SHAW (*Oregon Sta. Bul.* 408 (1942), pp. 30, figs. 20).—The loss of livers, flesh, and milk from cattle in the State, where limited observations at an Albany packing plant revealed 20 to 33 percent of the slaughtered cattle more than 2.5 yr. of age to show evidence of fluke presence, led to the investigation here reported. Reference is made to the finding of Krull (*E. S. R.*, 84, p. 394) of an even higher percentage of fluke injury in Utah. The study was conducted with the view to determining the extent of the pathology produced in livers by this trematode, the activity of the parasite within the

liver, and the resulting tissue responses. The observations made as to the effects of this fluke on its bovine host indicate them to be limited to a mild anemia and eosinophilia and slight, if any, lowering of general body condition. The most marked alterations are produced by this parasite in the bile ducts and consist in the sclerosis of lamina propria, muscle wall, and perimuscular connective tissues, a reactionary hyperplasia of the epithelium with an elaboration of a mucin-like substance, the deposition of inorganic salts in the mucosa, and an erosion and necrosis produced by parasites inhabiting them. In naturally infested animals damage incurred in the hepatic parenchyma is relatively slight. When more severe injury is produced by a heavy infestation, it may be offset by compensatory hyperplasia in other parts of the organ. An increase in interlobular connective tissue was frequently observed, especially in proximity to infested ducts.

The thickening of Glisson's capsule, presence of focal subcapsular lesions, and the metaplasia seen in overlying peritoneum are submitted as suggestive histological evidence that the young fluke probably reaches the choleic ducts by migration from the peritoneal cavity through Glisson's capsule and the hepatic parenchyma. The recovery of young flukes from a typical subcapsular lesion of a yearling heifer injected intraperitoneally with 3-day-old flukes further indicates that these parasites reach the liver by this route.

Considering the value of liver tissue as a food and therapeutic agent, the observations reported indicate that special effort should be made under adequate supervision to utilize mildly infested organs that are now discarded without consideration.

Sneezeweed, "fifth columnist" in sheep production, combated by management. C. W. DORAN. (Coop. U. S. D. A.). (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 3, pp. 5-7, figs. 3).—A practical discussion of the orange or western sneezeweed [*Helenium (Dugaldia) hoopesii*], a source of serious loss of sheep on many high-altitude summer ranges in western Colorado. It now infests more than 1,500,000 acres of summer range land in the State and is constantly spreading. The plant also occurs in 10 other Western States and particularly in Utah.

Reference is made to a study of two bands of range ewes and lambs in which the death losses, lamb weights, lamb crops, and gross income from the sale of lambs were recorded during three consecutive seasons. Data, presented in table form, show the effects of management and demonstrate conclusively that range infested with poisonous plants can be used most profitably only when sheep are properly handled. When good or improvement management replaced poor management in either of the bands studied, death losses from sneezeweed poisoning were reduced more than 80 percent and from 22,000 to 26,000 more pounds of lamb were produced and marketed, resulting in an increased gross income of from \$2,000 to \$2,400.

A description is given of the management practices found to have a marked effect on decreasing losses and increasing production of sheep on such infested ranges as are recommended.

Earlier work with *H. hoopesii* by Marsh and his associates has been noted (E. S. R., 46, p. 82; 52, p. 480).

"Wobblers" compared with ataxic ("swingback") lambs. P. OLAFSON (*Cornell Vet.*, 32 (1942), No. 3, pp. 301-314, figs. 10).—The author calls attention to the similarity between wobblers and ataxic lambs, both of which occur in young animals reared on limestone soil. The symptoms, lesions, and progress of the diseases in affected animals are much the same. Investigators have shown that the administration of copper to pregnant ewes kept in "swayback" regions markedly decreases ataxia in the lambs. Copper administration should be tried on pregnant mares to see if this would prevent the development of wobblers.

Blood from wobblers and their dams and the livers from wobblers should be analyzed for copper.

Studies of parasites in Oregon sheep on irrigated pastures, J. N. SHAW and O. H. MUTH (*Oregon Sta. Bul.* 402 (1942), pp. 16, figs. 10).—This progress report of a study under way deals with the effect of parasites, particularly the small stomach worm (*Ostertagia circumcincta*) and the small intestinal worm (trichostrongyle) in lambs and old and young ewes on pasture, some of which were treated with phenothiazine. Other helminths found present included the eastern stomach worm (*Haemonchus contortus*), *Strongyloides papillosa*, *Bunostomum trigonocephalum* (hookworm), *Nematodirus filicollis*, *Ohabertia ovina*, *Trichuris ovis*, *Moniezia* sp. (tapeworm), and *Dictyocaulus filaria* (lungworm). The animals were held on pasture plats in 1940 and 1941 with supplements of wheat and barley. Only 8 of 95 lambs became fat in 126 days on irrigated Ladino clover pastures, a death loss of 17 of the lambs having resulted from parasitism. The worm load estimated averaged 7,856 in 14 stomachs and 14,091 in 13 small intestines. The symptoms included extreme loss of weight, scouring, and thirst, no bloat having been observed. Treatment applied after clinical symptoms appeared was unsuccessful.

Observations on the blood-picture of sheep treated with phenothiazine, H. H. HOLMAN and I. H. PATTISON (*Vet. Rec.*, 54 (1942), No. 22, pp. 215-216).—It is concluded that the therapeutic dose of phenothiazine for lambs is from 10 to 20 gm., but no specific change was detected in the blood of 25 lambs receiving more than this dose.

A note on the possible anthelmintic value for sheep of phenothiazine incorporated in feed or lick, H. M. GORDON (*Jour. Council Sci. and Indus. Res. [Austral.]*, 15 (1942), No. 1, pp. 54-55).—It is concluded that until further work has been conducted the administration of phenothiazine in salt licks or in a food supplement cannot be recommended.

Further studies of diseases affecting moose, III, R. FENSTERMACHER and O. W. OLSEN (*Minn. Expt. Sta.*). (*Cornell Vet.*, 32 (1942), No. 3, pp. 241-254).—This third contribution reports upon the examination and study of five additional animals (*E. S. R.*, 77, p. 544). One of the animals, a young male, was affected with brucellosis, and a second died as the result of an extremely heavy infestation of liver flukes (*Fascioloides magna*). There was no evidence of extensive encephalitis in any of the five animals, but it is pointed out that the idea or possibility of a neurotropic virus as a factor has not been abandoned.

Studies on feeding zinc to pigs, J. SAMPSON, R. GRAHAM, and H. R. HESTER (*Univ. Ill.*). (*Cornell Vet.*, 32 (1942), No. 3, pp. 225-236, figs. 8).—Following a brief review of the results of studies of other investigators which seem to warrant the conclusion that the body probably has a specific need for zinc and can tolerate a reasonably larger intake than the normal requirement, although the consumption of a large amount for an extended period may possibly prove harmful, the results of an investigation undertaken at the Illinois Experiment Station in 1937 are reported. Shoats weighing from 75 to 100 lb. and weanling pigs were fed zinc lactate. Lameness and arthritis occurred in the smaller pigs, but no ill effects were observed in the larger animals. The results obtained in the trial with weanling pigs tend to confirm the observations reported by Grimmer and his associates (*E. S. R.*, 77, p. 836) that feeding young pigs 0.1 percent of zinc as zinc lactate in milk for an extended period produces unthriftiness, lameness, and arthritis. The authors consider it probable that the experimental results here recorded do not occur under natural swine-raising conditions in the United States.

The occurrence of Salmonella in the lymph glands of normal hogs, H. L. RUBIN, M. SCHERAGO, and R. H. WEAVER (*Univ. Ky.*). (*Amer. Jour. Hyg.*, 36

(1942), No. 1, pp. 43-47).—The mesenteric lymph glands from apparently normal hogs were examined for the presence of *Salmonella*, using the tetrathionate medium of Kauffmann for enrichment. Of 40 lots of hogs consisting of 25 animals each, 19 yielded *Salmonella*. Of 50 hogs examined individually, 5 yielded *Salmonella*. The types of *Salmonella* which were isolated are as follows: *S. typhimurium*, *S. choleraesuis kuzendorf*, *S. oregon*, *S. anatum*, *S. give*, *S. bareilly*, *S. derby*, *S. new-brunswick*, *S. bredeney*, *S. enteritidis*, *S. lexington*, *S. newington*, and *S. worthington*.

Grass silage—a hazardous horse feed, A. T. and R. GILYARD (*Cornell Vet.*, 32 (1942), No. 3, pp. 317-321).—Attention is called to the danger of feeding grass silage to horses. It is pointed out that any silo and method of preparation can have areas of incomplete curing in which the botulism organism (*Clostridium botulinum*) may develop, and the report indicates that the products of putrefaction in these areas may not be particularly deleterious to bovines yet hold potential disaster for horses. In the case described, the silo under consideration was of wooden construction with a concrete foundation. The silage was oats and field peas, and molasses was added in the proportion of 110 lb. to the ton. Consistent clinical observations, combined with the absence of gastrointestinal symptoms, in nine patients observed within 72 hr. strongly support the diagnosis of botulism. It is also significant that prophylactic use of polyvalent antitoxin apparently protected the remaining two patients that were on a ration including silage. The therapeutic value of antitoxin was insignificant.

Equine virus abortion, W. W. DIMOCK, P. R. EDWARDS, and D. W. BRUNER (*Kentucky Sta. Bul.* 426 (1942), pp. 20, figs. 5).—A practical summary is given of the status of knowledge of virus abortion based in large part upon work conducted at the Kentucky Station since 1932, during which time 19 outbreaks of this affection in mares, including 119 abortions, all of which occurred in the State, were studied. The pathological changes noted in the aborted fetuses were small necrotic areas in the liver, hemorrhages on the thoracic and abdominal viscera, and an accumulation of fluid in the pleural cavity. Intracellular inclusion bodies were present in the liver and lungs. No such inclusions were found in the tissues of fetuses not affected with virus abortion. The disease is known to exist also in Virginia and California, and reports indicate it to be present in other localities of the United States and Canada. Seventeen cases of abortion of mares in Germany were described in 1937, confirming the findings of Dimock and Edwards that the disease was caused by a virus. The infection was also reported in Yugoslavia and in Hungary in 1938.

Included in the account are (1) a description of outbreaks, (2) findings in post-mortem examination of fetuses and foals, (3) transmission experiments with mice, rabbits, guinea pigs, and eggs, in addition to mares, (4) treatments for immunization of mares, and (5) observations on the transmission and control of the disease.

Earlier contributions on the work at the station by Dimock and his associates have been noted (*E. S. R.*, 77, p. 102; 83, p. 309).

Infectious equine encephalomyelitis in the United States in 1941 (*North Amer. Vet.*, 23 (1942), No. 7, pp. 461-463, figs. 3).

Observations on phenothiazine as an anthelmintic in horses and with reference to blood examination, T. GRAHAM, J. E. N. SLOAN, and P. G. D. MORRIS (*Vet. Rec.*, 54 (1942), No. 22, pp. 213-214).—In experiments with phenothiazine to determine its effect upon the horse, the results of which are presented in tables, the fluctuations of the blood cells were so slight as not to be of any great significance. It is concluded that eosinophilia is not necessarily a concomitant of strongyle infection even when aneurysms are present. The data obtained from four horses show that phenothiazine administered at dose rate of

25-30 gm. per horse gives excellent results against all the smaller strongyles and *Strongylus* spp. and moderate results against young stages of *Oxyuris equi*, but has no effect on adult *O. equi* and immature *Parascaris equorum*.

An epizootic of canine distemper in a zoological park, W. H. ARMSTRONG and C. H. ANTHONY (*Cornell Vet.*, 32 (1942), No. 3, pp. 286-288).—In an outbreak of canine distemper in a large zoological park collection of various Canidae the virus proved infectious for several related species, including the common dog and ferret, red fox, eastern gray fox, kit fox, raccoon dog (*Canis procyonoides*), and Australian dingo. Following the appropriate prophylactic and therapeutic use of a commercial dog distemper antiserum on several related canine species, no new cases or deaths occurred.

An improved diagnostic stain for distemper inclusions, W. G. PAGE and R. G. GREEN. (Univ. Minn. et al.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 265-268).—Description is given of a new staining technic for the demonstration of the cytoplasmic inclusions of canine distemper applicable to both paraffin sections and fixed smears for rapid diagnosis. It is superior to hematoxylin eosin in the demonstration of small inclusions and gives greater differentiation between inclusion bodies and cytoplasmic artifacts.

A non-virulent, single-dose vaccine for prophylactic immunization of dogs, L. T. WEBSTER and J. CASALS (*Jour. Expt. Med.*, 76 (1942), No. 2, pp. 185-194).—The authors have found that a single injection of nonvirulent irradiated vaccine, prepared in the manner described, immunizes mice and dogs effectively against a subsequent test inoculation of virulent rabies virus and does so to a greater degree than do other vaccines now obtainable. It is easily and quickly prepared, keeps well, and has a low nitrogen content.

Thiamin deficiency and Chastek paralysis in foxes, A. Z. HOBSON and S. E. SMITH. (Cornell Univ. et al.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 280-285).—In the investigation here reported the clinical symptoms of anorexia, weakness, ataxia, spasms, and lowering of the body temperature were observed in foxes fed a thiamin deficient diet. These symptoms are apparently identical with those of foxes suffering from Chastek paralysis as a result of feeding an adequate diet with added uncooked fish (smelt). Both conditions were cured completely with thiamin chloride. Chastek paralysis was not cured by pyridoxin, riboflavin, or calcium pantothenate. A diet suitable for the determination of the thiamin requirements of foxes is given. The work supplements that reported by Green et al. (*E. S. R.*, 85, p. 672).

[Work in avian pathology by the Massachusetts Station] (*Massachusetts Sta. Bul.* 388 (1942), pp. 99-103).—The work of the year on diseases of fowls (*E. S. R.*, 85, p. 815) reported upon by H. Van Roekel, K. L. Bullis, O. S. Flint, M. K. Clarke, and C. Olson, Jr., included pullorum disease eradication, flock mortality, isolation of *Salmonella* types, avian encephalomyelitis, infectious bronchitis, and neoplastic and neoplasticlike diseases (*E. S. R.*, 87, p. 721).

Salmonella bredeney infection in birds, W. R. HINSHAW, T. J. TAYLOR, and E. McNEIL. (Univ. Calif.). (*Cornell Vet.*, 32 (1942), No. 3, pp. 337-339).—The authors report upon the presence of *S. bredeney* in chukars (*Alectoris chukar*), turkeys, and ducks in California. An outbreak of paratyphoid in chukars from which both *S. typhimurium* and *S. bredeney* were isolated is described.

Un nuevo tratamiento para el moquillo [A new treatment for avian diphtheria], C. M. MUÑIZ and R. MORENO (*Agr. Expt. [Puerto Rico Univ. Sta.]*, 2 (1942), No. 3, p. 8).—The value of sulfathiazole, administered for 10 days at the rate of 0.25 gm. to each ounce of food, in the treatment of avian diphtheria is pointed out. Such treatment, however, is not a substitute for approved sanitation and the proper food ration, which should include cod-liver oil with vitamin A.

Coccidiosis control in chickens, E. M. DICKINSON (*Oregon Sta. Bul. 405* (1942), pp. 23, figs. 7).—This is a practical account of coccidiosis, including (1) the cecal form, commonly encountered during the brooding period and characterized by bloody diarrhea, and (2) the intestinal form, commonly met with in young pullets and characterized by sudden loss of appetite, drop in egg production, and "going light." Resistance against a species of coccidia develops following a suitable infection with coccidia of that species, but resistance developed by one species will not protect against infections by other species of coccidia. Outbreaks of these forms are brought under control by daily cleaning the poultry house for a period of 5 to 7 days. Moist mash or a brief nutritional flush that will stimulate the appetite may help to a more prompt recovery. A system of management and sanitation based on knowledge of the parasite may check or prevent the regular occurrence of outbreaks of clinical coccidiosis.

Sulfonamide therapy of malaria in ducks, E. K. MARSHALL, JR., J. T. LITCHFIELD, JR., and H. J. WHITE (*Jour. Pharmacol. and Expt. Ther.*, 75 (1942), No. 1, pp. 89–109, figs. 7).—The authors have found the maintenance of a more or less constant blood concentration of a sulfonamide drug for a sufficient length of time to be just as important for effective therapy in *Plasmodium lophurae* infections in ducks as it is in bacterial chemotherapy. The degree of parasitemia in treated ducks at the time when untreated birds are at the height of their parasitemia can be used as a criterion of effectiveness of therapy. Under experimental conditions the degree of parasitemia on the sixth day after infection was correlated with survival time and percentage survival. The antimalarial activity of a number of sulfonamides and sulfones has been tested. Para-aminobenzoic acid has slight antimalarial activity and has a definite antagonistic effect on the antimalarial action of sulfonamide drugs. A list of 30 references to the literature cited is included.

Studies on the host-parasite relationships of untreated infections with *Plasmodium lophurae* in ducks, R. HEWITT. (Univ. Tenn. et al.). (*Amer. Jour. Hyg.*, 36 (1942) No. 1, pp. 6–42, pls. 2, figs. 10).—Report is made of observations on the course of untreated infections with *P. lophurae* in approximately 300 ducks of mixed ages, weights, and breeds. Over 75 percent of 30 young ducks infected (from 4 to 7 weeks old) died from what appeared to be the effects of the parasite, and infections in from 10 to 15 percent of approximately 250 adult ducks terminated fatally. The findings are presented under the heading of susceptibility of young and adult ducks to infection with *P. lophurae*, hematology of unparasitized ducks, changes which occur in the blood of ducks infected with *P. lophurae*, and temperature and periodicity studies. A list of 26 references to the literature is included.

Parasite free poultry produces, M. W. EMMEL. (Fla. Expt. Sta.). (*Fla. Grower*, 50 (1942), No. 6, pp. 14, 15, fig. 1).—Treatments that end chicken flock losses due to ectoparasites are described.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Arizona Station] (*Arizona Sta. Rpt. 1941*, pp. 21–29, fig. 1).—These included studies of ground water in the upper Santa Cruz Valley, the Cortaro-Marana district, the Eloy district, and the Little Chino Valley; physiographic correlations (E. S. R., 80, p. 304); wells and pumping machinery; forecasting the water supply; and the tamarisk tree and its wood.

[Agricultural engineering investigations by the Massachusetts Station] (*Massachusetts Sta. Bul. 388* (1942), pp. 49–50).—These included a cranberry

storage investigation by C. I. Gunness, H. J. Franklin, and C. R. Fellers; an apple storage investigation, by Gunness; and a poultry house investigation, by Gunness and W. C. Sanctuary.

[Agricultural engineering work by the New Haven Station] (*Connecticut [New Haven] Sta. Bul. 452 (1942), p. 14*).—A portable charcoal kiln and a study of the use of native hardwoods for fencing are reported upon by W. O. Filley et al.

Percolation and water requirement studies with alfalfa by means of lysimeters in Oregon, S. H. HASTINGS and H. K. DEAN. (Coop. U. S. D. A.). (*Oregon Sta. Bul. 404 (1942), pp. 16*).—Experiments carried out at Umatilla with eight lysimeters from 1915 to 1931 are reported in detail. One unit was uncropped, one planted to soybeans in the summer and vetch in the winter, and the remaining six to alfalfa. Five soil types ranging from a sandy type to a fine silt loam were used. For the 1922–31 period the mean percolation from the six lysimeters filled with sandy soil and having mean annual water applications of 60.5 in. ranged from a maximum of 72 percent for the uncropped unit to a minimum of 7 percent from that cropped to alfalfa. For the same period the mean seasonal water input applied to lysimeters seven and eight filled with finer-textured and more productive soils was 116.85 in., and the percolations were only 9 and 8 percent, respectively. Losses by evaporation from an uncropped lysimeter were 0.54 percent as much as from an evaporation tank.

For the 10-yr. period 1922–31 the seasonal water requirements of alfalfa, in inches of water per ton of hay produced, ranged from a minimum of 8.8 to a maximum of 11.50. The more productive soils proved to be the more economical in the use of water. Approximately doubling the water input, i. e., using 116.85 compared with 60.5, not only returned the highest yield of alfalfa but resulted in a highly efficient use of the irrigation water on the more productive finer-textured soil types. The computed yields of alfalfa per acre from lysimeters filled with rather sandy soil types were somewhat in excess of those harvested from comparable soils under favorable conditions in the Umatilla area. Such results were obtained with water inputs of approximately 5 ft. When this amount of water was applied to a lysimeter in which a productive silt loam soil was utilized, the indicated yield per acre was 7.72 tons. When the water inputs were nearly doubled or increased to 118.46 in. annually the mean yield of alfalfa was increased to 15.44 tons per acre. These substantially increased yields are attributed to (1) the use of productive soils, (2) heavy water applications, and (3) such frequent water applications that the soil moisture was maintained at more nearly the optimum.

Water-disposal planning techniques, W. A. WEID. (U. S. D. A.). (*Agr. Engin.*, 23 (1942), No. 5, pp. 152–154, figs. 2).—Improvements in such technic since the inception of the soil conservation program in the southeastern United States 8 yr. ago are summarized. Developments mentioned included adaptation of stereoscopic delineation and analysis of natural drainage features on aerial photographs as an initial step in the planning process, the introduction of water-disposal planning carried out with, instead of after, erosion control and land-use planning, use of meadow outlets and disposal areas capable of yielding a hay or grazing return, special treatment of critical areas within cultivated fields, etc. Emphasis is placed especially upon the recently evolved practice of planning water disposal on a unit watershed basis rather than on the basis of the arbitrary unit of a single farm, and the application of stereoscopic analysis, as above noted, to the study of such watersheds. This type of analysis has the advantages of an effective approach to group action

in the district program providing basic information for use in developing over-all conservation plans for an action program on flood control and land utilization projects; pertinent information applicable to preliminary investigations for drainage surveys; a sound basis for subdividing large tracts of land, along with land-use capabilities; a means whereby highway erosion-control plans may be directly correlated with water-disposal and land-use planning; and a definite aid to water-disposal planning on the individual farm basis, since natural drainage features are identified and properly correlated with those on adjacent lands.

Tilt buckets for measuring run-off and erosion, C. N. JOHNSTON. (Univ. Calif.). (*Agr. Engin.*, 23 (1942), No. 5, pp. 161-162, figs. 3).—For 50-ft. squares of experimentally burned and unburned range brushland it was necessary to devise means for measuring rates of water flow too small to be determined with certainty by means of 90° V notch weirs and stage recorders. The author describes a set-up consisting essentially of a tilt bucket of a capacity on each side of 1 or of 5 cu. ft., the radii being 15 and 21 in. and the face length from 20 to 48 in., respectively, together with arrangements necessary for recording the frequency of tilt with respect to time by means of a stage recorder. Oil dash pots were found a necessary addition to the larger tilt buckets, and pots of a diameter 3 in. or greater were required to prevent breaking of the oil column on the upstroke, with loss of a part of the oil. No. 30 S. A. E. oil was used and a piston clearance of $\frac{1}{16}$ in. A divider taking an aliquot of one twenty-fifth of the contents of each side of the tilt buckets was used for the sampling and was shown to give a silt : water ratio consistently close to that of the stream flowing into the bucket.

Terrace grades on Shelby soil as they affect soil and water losses, A. W. ZINGG. (U. S. D. A. and Mo. Expt. Sta.). (*Agr. Engin.*, 23 (1942), No. 5, pp. 159-160, 162, fig. 1).—In a study covering a 9-yr. period, the total runoff and the number of runoff periods increased with terrace channel grade up to grades of 8 in. per 100 ft. Average maximum rates of runoff for 128 runoff periods increased with channel grade. The average maximum was 5 times greater on the 8-in. grade than on the level terrace. The variable-grade terrace was superior to a terrace of uniform grade. It had the capacity to retain a relatively large volume of rainfall and also to discharge runoff at relatively high rates when hydraulic efficiency was most needed. There was no significant difference in the total time of runoff from terraces of various grade for the 9-yr. period. Total soil loss in runoff increased logarithmically with terrace grade. Increasing the channel grade from level to 8 in. per 100 ft. approximately multiplied the soil loss in runoff by 7 for corn, 4 for small grain, and 3 for meadow crops. Channel grades of less than 2 in. per 100 ft. were not practical on the Shelby soil. Level terraces were satisfactory only on Grundy silt loam ridge tops, where the direction and degree of slope were uniform and the depth of surface soil exceeded 12 in. Channel grades up to 6 in. per 100 ft. may be safely used on the Shelby soil.

Maintaining open drainage ditches by grazing, H. MATSON. (U. S. D. A.). (*Agr. Engin.*, 23 (1942), No. 5, p. 169, figs. 4).—In the areas of south Louisiana studied by the author, willows, sawgrass, alligator grass, water hyacinths, and cattails cause most of the choking and filling of drainage ditches and are the vegetative types most difficult to control. While some of these vegetative types are not actually grazed by livestock, they are effectively controlled in shallow water and along well-shaped ditch banks by the trampling which occurs in a closely grazed pasture. Accompanying illustrations show clearly that drainage ditches in south Louisiana which are not pastured or otherwise maintained may

become almost completely choked and filled within 5 yr., while ditches which have been closely grazed are still in good condition after 20 yr. or more of service. The use of moderate slopes, seeding or sodding, and grazing of ditch banks for the control of erosion and undesirable vegetative growth should be effective in most sections of the United States. To make this possible it will be necessary to fence the ditch, including a strip of land on each side of it, wherever a main or lateral ditch passes through or by land which is not already in pasture, and to provide swinging flood gates at each fence crossing. Arrangements for community grazing may be made to reduce the number of flood gates needed.

Efficiency of combine at various stubble heights, E. A. SILVER. (Ohio State Univ.). (*Agr. Engin.*, 23 (1942), No. 5, p. 168).—The author describes field experiments leading to the definite conclusion that if a combine is operated at a stubble height much lower than 10 in., considerable grain losses will result, and that these may be of such magnitude as more than to counterbalance the value of the straw. At a stubble height of 6 in. the rack loss alone amounted, on one variety, to 26.5 percent. When the machine showing the least loss was set for a 10.5-in. stubble the greatest loss was 5.6 percent. In the case of a 15-in. stubble the loss was practically negligible. The variety of grain and the adjustment of the machine had a marked effect on the extent of the grain losses. The data obtained included records of the grain losses at the cylinder, straw rack, shoe, and cutter bar and power requirements for both power take-off and drawbar.

Equipment combinations for harvesting cornstalks, A. P. YERKES (*Agr. Engin.*, 23 (1942), No. 5, p. 166).—The author describes an experiment carried out on a farm in southern Wisconsin where the fodder was considerably smaller than that commonly found in the Corn Belt proper. Most of the stalks ranged from 6 to 8 ft. in height, but care had been exercised in operating the picker to avoid having wheels run directly over the rows so that the fodder had a higher percentage of stalks still standing with half their lengths erect than is often found. The forage harvester was a 42-in. cut. Its cutter bar was equipped with two grain lifter guards, one running on each side of the row. These guards lifted a great many pieces of stalks from the ground, making them pass over the cutter bar, and also saved many of the top halves of stalks which were hanging from upright stubs. The regular cutter head used for cutting grass or corn for silage did a good job of cutting up the fodder but left many short cylindrical pieces which, after being delivered into the feed chamber of the baler, tended to roll to the bottom and made a very uneven bale. When the cutter head was replaced by one which did not cut but tended to shred the fodder, a satisfactory bale was produced, but the amount of fodder which could be cut and baled per hour with this four-man outfit, taking only one row, would probably be too small, even where the yield was heavy, to make it economical.

An experiment in which a tractor mower and pick-up baler were successfully used behind the combine for cutting and baling straw is also described.

Harvesting cornstalks for industrial use, J. B. DAVIDSON, C. K. SHEDD, and E. V. COLLINS. (Iowa Expt. Sta. and U. S. D. A.). (*Agr. Engin.*, 23 (1942), No. 5, pp. 163-164, fig. 1).—The best labor economy of 13 yr. ago was obtained by a combined harvesting outfit consisting of a mower, a hay loader, and a threader baler with automatic feed driven from a power take-off. During the past year the Iowa Station has studied the windrow pick-up baler. Three methods of breaking and loosening the stalks were tried out—(1) low cutting knives attached to the tractor pulling the side-delivery rake putting the stalks into a windrow, (2) harrowing down with smoothing harrow, twice over, and (3) cutting stalks with a conventional tractor stalk cutter drawn ahead of the side-delivery rake. None of these methods proved entirely satisfactory from the viewpoint of raw material quality, however, and the experiments as a whole

indicated that the stalks must be harvested at the time the ears are harvested and kept off the ground as far as practicable. This will require development of a suitable drying or curing procedure. Partial processing on the farm to retain the more edible portions, useless for pulp manufacturing, is much to be desired, and "if cornstalks are ever to be in demand by manufacturers with the present competition of raw materials from other sources, the process of harvesting must be fully mechanized and the raw material supplied not only at an inviting figure but with a satisfactory return to the farmer." The authors consider the field a promising one for engineering investigation, however.

Baling straw with the pickup baler, A. J. SCHWANTES. (Univ. Minn.). (*Agr. Engin.*, 23 (1942), No. 5, pp. 164-165, 167, fig. 1).—This is a brief summary of practices in the use of this machine as found in Minnesota. The computed cost of baling per ton of straw is given as \$1.57, owner's estimate \$1.73, and charge for custom work \$2.62; tons per acre (yield) 0.52, tons per hour (rate of baling) 2.02, average size of crew 3.55, and man-hours per ton 1.77; hauling distance 0.25-10 miles, tons per hour hauled 2.10, average number of men in crew 2.8, man-hours per ton hauled 1.34, and truck-hours per ton hauled 0.54; and data on weight of bales 76.5 lb., density 12.4 lb. per cubic foot, and moisture content, percent (11.75-17.15) 14.0.

Weed control in growing corn, C. K. SHEDD, E. V. COLLINS, and J. B. DAVIDSON (*Iowa Sta. Bul. P44, n. ser.* (1942), pp. 437-467, figs. 23).—General methods of combating weeds are outlined. Improved equipment which enables the careful farmer to improve the control of weeds in cornfields is described, as are methods of seedbed preparation which assist in control of weeds without excessive input of labor or power. The principal purpose of cultivation of corn is to control weeds, but early cultivation to control sand-blowing is also essential under some conditions.

For early cultivation of corn, the spring tooth weeder and the rotary hoe were effective in killing weed seedlings when the soil surface was lightly crusted by moderate rainfall, but they were not very effective when the soil was heavily crusted by intense rainfall nor when the soil surface was loose and dry. The best cultivator equipment for use when corn plants were small consisted of six sweeps per row and rotary hoe shields. When first cultivation could be delayed until corn plants had grown about six leaves, it was found best to leave off the shields and use half sweeps next to the corn row. The best equipment for second cultivation under usual conditions was one pair of disk hillers throwing soil into the corn row and two pairs of sweeps per row. Experimental scrapers on the disk hillers prevented coverage of corn plants. For the last cultivation the best equipment was the same as for second cultivation, except that scrapers on the disks were not needed. An experimental spring tooth weeder rear attachment for a tractor cultivator was effective in filling tractor wheel tracks, leveling the soil between corn rows and improving weed control. Speed of travel of cultivators to do the best job of destroying weeds was generally between 2.5 and 4 miles per hour.

Three cultivating programs are suggested for check-rowed corn with a view of improving weed control and keeping labor and power input at a minimum.

Spray machinery for orchards, gardens, truck crops, T. E. ASHLEY (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 7, pp. 3-5, figs. 14).—Drawings and descriptions of motorized hand sprayers twice previously described are included in an article of essentially the same content as in Circular 106 (E. S. R., 82, p. 263; 87, p. 728).

Cotton ginning for pure-seed preservation, C. A. BENNETT and F. L. GERDES (*U. S. Dept. Agr. Leaflet 217* (1942), pp. 8, figs. 5).—This leaflet points out the means by which the mixing of seed of different varieties of cotton can be pre-

vented during the ginning processes and also the precautions which must be taken at any gin to make it suitable for the preservation of seed purity. Methods considered practical consist in the use of (1) self-cleaning belts, (2) self-cleaning blowpipe systems, (3) gravity chutes in two-story gins, and (4) combinations of (1) and (2). Systems now in use for putting these methods into practice comprise: (1) A horizontal flat seed belt in a smooth trough below the stands, delivering either to an inclined belt or to a seed-blowing pipe through a vacuum wheel seed feeder. (2) A reversible horizontal flat seed belt beneath the stands, operating in one direction to deliver gin-run seed and in the other to deliver pure seed, each discharging into disposal apparatus by various means. (3) Two individual conveyors beneath the stands, gin-run seed being handled in the front system and pure seed in the rear one, or vice versa, each screw system having its own lifts and deliveries. The pure-seed system, of course, is completely accessible for cleaning between runs. (4) In two-story gins gravity chutes with hinged covers in front of or below each gin stand, diverting pure seed by gravity into funnels, sacks, or belts below. A standard screw conveyor is generally used on gin-run seed. (5) Gravity chutes similar to those described above, short enough for single or two-story gins, delivering pure seed from each gin stand into a blowpipe by means of individual rotating vacuum-wheel seed feeders.

It is pointed out that when elevation of cotton seed is necessary, only the blowpipe or inclined-belt systems can be regarded as self-cleaning. Vertical screw and bucket-type elevators cannot be depended upon to be fully self-cleaning even when seed from several bales have been run through the system in an effort to clean it before commencing to save planting seed.

Wheat storage in experimental farm-type bins, C. F. KELLY, B. M. STAHL, S. C. SALMON, and R. H. BLACK. (Coop. N. Dak., Kans., Md., and Ill. Expt. Stas. et al.). (*U. S. Dept. Agr. Cir. 637 (1942), pp. [2]+245, figs. 33*).—This circular brings up to date findings concerning wheat moisture contents safe for storage in various types of storage structures on the farm in the various wheat-growing areas, supplementing similar results recorded in previous circulars (E. S. R., 83, p. 687; 85, p. 546) and in journal articles (E. S. R., 86, pp. 397, 840). Following a brief introduction and outline of the procedure, it takes up deterioration of wheat in storage; wheat storage in North Dakota, Kansas, Maryland, and Illinois; surveys of bins on farms; underground storage of wheat; changes in fat acidity and germination of wheat from selected locations in stored bulks; use of fungicides, insecticides, and absorbents in farm wheat storage; and the moving and conditioning of wheat. An extensive appendix of numerical data occupies more than one-third of the circular.

Performance of cowls for ventilated grain bins, C. F. KELLY, M. G. CROPSKY, and W. R. SWANSON. (U. S. D. A.). (*Agr. Engin., 23 (1942), No. 5, pp. 149-151, figs. 3*).—In tests of four different types of bin ventilators, two pressure and two suction, at Fargo, N. Dak., it was found that the air pressure developed by the pressure cowls closely approached the velocity pressure of the wind. The negative pressures developed by a turbine ventilator and a suction cowl were only about 40 percent as great, however. Of the cowls or duct systems tested, only two, which were not on test during periods of highest winds, excluded all snow, indicating that ventilators should be closed during the winter months. It was observed that in storms with ordinary wind velocities louvers were of benefit in excluding snow from pressure cowls, and that the suction ventilators did not catch as much snow as the open-face pressure cowls. Of the two ventilators which excluded all snow in winds reaching 27 and 23 miles per hour in their respective test periods, both were of T trap construction, the lower end of the vertical crosspiece of the T being closed except for a small

drainage opening. The first communicated directly with the down pipe through the wheat by way of an elbow turning downward from the side arm of the T. This ventilator had an adjustable damper in the vertical arm of the T above the side arm. The second of the trap ventilators, without damper, had a side arm in the form of an elbow turning upward into a return bend from which the air entered the down pipe through the wheat. The down pipes of both of these ventilators delivered the air into the bin through screened ends 18 in. below the top of the wheat layer.

The farm freezing plant, W. H. MARTIN and F. E. PRICE (*Oregon Sta. Bul. 399 (1941), pp. 19, figs. 6*).—This bulletin discusses the following plans for the freezer plant preservation of family food supplies, pointing out their respective advantages and disadvantages and indicating the nature of the equipment required and the initial and operating costs of each: Use of a rental locker plant entirely, with no farm refrigerator; a rental locker plant with a standard household refrigerator; a rental locker plant with a household refrigerator having a 1- to 6-cu. ft. freezer compartment or a separate 6-cu. ft. freezer refrigerator; a large chest type farm freezer and renting of space to chill and age meat before freezing; and a two-compartment farm freezer plant with both 0° and 35° F. storage. With reference to the equipment of which a part is to be built by the owner, the bulletin takes up insulation; vapor barrier; general, wall, ceiling, and door construction; the home-built door; interior wall and door finish; refrigeration surface; power consumption; controls; defrosting; electrical service; and cost. Sections and floor plans for the construction of a plant including a 35° and a 0° room of from 130 to 200 and 44 cu. ft. capacity, respectively, are included, together with detailed drawings for stock door installation and for home-built doors for each of these rooms.

Engineering performances of a multiple-baffle electric sterilizer, J. E. NICHOLAS. (Pa. Expt. Sta.). (*Agr. Engin.*, 23 (1942), No. 5, pp. 155-156, figs. 2).—The temperatures of dairy utensils as recorded by thermocouples attached to them during a sterilizing process are reported. With a sterilizer designed to provide a more uniform heating of the utensils and when they were loaded as shown, the maximum and minimum utensil temperatures were 205.8° and 190.8° F. The maximum and minimum air temperatures were 227.5° and 192.1°. Higher or lower temperatures could be obtained by adjusting the thermostat.

The profit aspect of industrial use of farm residues, F. G. KRANICK (*Agr. Engin.*, 23 (1942), No. 5, pp. 164, 166).—The author discusses very briefly some of the differences of viewpoint between farmer and manufacturer which create problems in the industrial utilization of straw and cornstalks, mentioning as an illustration of some phases of the general problem a field where grain was harvested by a combine and the stubble cut with a 12-ft. windrower. This field of 47 acres was baled in 47 hr. and produced 1,121 bales of 60 lb. each, that is, 23.8 bales per acre, or 1,431 lb. of straw. This yield of 0.72 ton of straw per acre is low, and the result is not encouraging with respect to income, considering the amount of work and interest on equipment. The manufacturer's needs call for a fixed yield with short hauls to the factory and for a constant supply year after year, whereas farm yields vary with many factors, some of them not controllable or predictable. The farmer desires heavy grain yields and short straw, whereas the strawboard mill prefers abundant long straw at a moderate price. A further complication is presented by the fact that "the strawboard mills are in Illinois, Indiana, Ohio, etc., where the straw is useful to the farmer. In the West, in such States as Nebraska, Kansas, South Dakota, and North Dakota, they have straw to burn but no mills to use it."

Practical electrical wiring, H. P. RICHTER (*New York and London: McGraw-Hill Book Co., 1941, 2. ed., pp. X+521, figs. 457*).—In the preparation of the second edition some new material has been added, and the entire contents of the first edition have been retained. The present volume has been made to conform in all respects with the 1940 National Electrical Code. The book covers the wiring of structures of limited size and for ordinary voltages.

Spray painting of farm buildings, L. A. BUSE (*Agr. Engin., 23 (1942), No. 5, pp. 157-158*).—After some unsatisfactory initial experience, an insurance company having a large number of Midwest farms to prepare for resale found spray painting to be much more rapid and, in quality, equal to or better than brush painting. A four-man crew of two spray-gun operators and two helpers could put two coats of paint on an average set of farm buildings in 2.5 days, whereas the same work (10,000 sq. ft.) would require 10 days or more if done by a brush crew of four men. Cracked, checked, porous, and dust-covered siding boards were better protected by sprayed paint because paint so applied was driven into crevices, etc., instead of merely bridging them, as did paint applied with a brush.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Arizona Station, 1941] (*Arizona Sta. Rpt. 1941, pp. 16-18, 20*).—In addition to results previously noted, brief findings are included as to the relationship of soils in the Casa Grande Valley to cotton yields; the ability of farmers in the Wellton-Mohawk area of Yuma County to pay irrigation water costs; the average net farm income, cost of living, etc., in 1940 of 52 families with loans from the Farm Security Administration; and forms of Arizona farm leases.

[Investigations in agricultural economics by the Kentucky Station, 1941] (*Kentucky Sta. Rpt. 1941, pp. 35-41*).—In addition to findings previously noted, statements are included giving facts ascertained as regards farm management in a study of some 6,000 farms in the southwestern Pennyroyal region; adjustments for loss of income from dark tobacco in western Kentucky; the costs in 1940 of operating 43 tractors in Union and Henderson Counties as compared with the costs in 1930 of operating 36 tractors in Christian and Todd Counties; returns from beef-cow herds; changes in market outlets for Kentucky livestock; auction markets as outlets for Kentucky livestock; organization of tobacco auction markets; and trends in the demand and consumption of United States tobaccos.

[Investigations in agricultural economics and farm management by the Massachusetts Station, 1941] (*Massachusetts Sta. Bul. 388 (1942), pp. 4-7*).—In addition to results of studies previously noted, brief statements are included of findings in studies (1) of the Boston Regional Produce Market by A. A. Brown and M. Booth; (2) of vegetable growing in Bristol County and diversification of the farm business in Essex County, both by C. R. Creek; (3) of rural operations and credit in the State by A. H. Lindsey and S. Russell; and (4) of land tenure in the State by Lindsey and E. Collins.

Current Farm Economics, [August 1942] (*Oklahoma Sta., Cur. Farm Econ., 15 (1942), No. 4, pp. 109-140*).—In addition to the usual review of the agricultural situation and tables on prices, price indexes, and indexes of purchasing power of Oklahoma products, etc., articles are included on (1) Cotton in War Time, by K. C. Davis and W. A. Williams (pp. 115-130), which discusses the effect of war on cotton production in Oklahoma, the changes in the demand for cotton, the possibility of Oklahoma farmers adjusting production to meet the wartime demand, the effect of war on the price of cotton to farmers, the

grades and staple lengths that will be most in demand, how Oklahoma farmers may adjust production to receive a higher price for their cotton, and loan price v. market price; and on (2) Farm Labor as a Factor Affecting Agricultural Production in 1942 and 1943, by R. T. McMillan (pp. 131-137), in which the factors affecting the supply of agricultural labor, the prospective changes in demand, and the agricultural employment outlook for October 1942 and for 1943 are discussed. The author found no general shortage in agricultural labor was to be expected in Oklahoma for the remainder of 1942 and during 1943. "The prospect of a quality shortage in agricultural labor is imminent, with experienced first-class dairy workers, ranch laborers, tractor drivers, and combine operators being scarce during the next 18 mo. at least." One of the chief problems is the transportation of laborers. Wage rates of agricultural labor may be expected to advance still further. "More intensive use of available labor and machinery resources should minimize the chances of any acute labor shortage. . . . An over-all increase of 10 to 15 percent in the agricultural production for 1943 could be planned without any serious labor handicaps."

[Investigations in agricultural economics by the Wyoming Station, 1940-41] (*Wyoming Sta. Rpt. 1941*, pp. 7-9).—Brief statements are made as to the effects of (1) percentage of capital invested in livestock, productive work units per man, percentage of calf crop, number of cattle units, and production of beef per cattle unit upon returns on investment on livestock ranches in Sheridan and Johnson Counties; and (2) of work units per man, cows per man, and efficiency of feeding on returns on dairy farms in the Star Valley in Lincoln County.

Comparisons of criteria for the rating of agricultural land, J. O. VEATCH and I. F. SCHNEIDER. (Mich. Expt. Sta.). (*Mich. Acad. Sci., Arts, and Letters, Papers*, 27 (1941), pp. 441-447).—A comparison is made of ratings of land in Michigan by counties on the basis of money value per acre as given in the United States census with ratings on the basis of physical character of soil and land types and the generally accepted, though qualitative, productivity ratings of the types. The two ratings do not agree very closely. Possible criteria for the economic classification of agricultural land are listed. The conclusion is that a classification based upon a number of factors is likely to be of more value than one based upon a single criterion, but that no classification can be strictly mathematical because the necessary basic data are unobtainable.

Management of public land in North Dakota, M. H. TAYLOR and R. J. PENN. (Coop. U. S. D. A.). (*North Dakota Sta. Bul. 312* (1942), pp. 32, figs. 4).—The amounts and kinds of publicly owned lands held by different agencies, the acquisition of lands by and the sales and leasing programs of the agencies, the effects of public land management on farm and ranch operations, type of purchasers and lessees from different agencies, size of operations of purchasers and lessees, the changes in use of land accompanying changes in ownership, the effects of sales and leases on security of tenure, etc., are discussed. Suggestions are made for the improvement of the management of public land.

Budgeting in Texas Counties in terms of living within available resources, H. C. BRADSHAW. (Tex. Expt. Sta.). (*Southwest. Social Sci. Quart.*, 21 (1941), No. 4, pp. 325-334).—This discussion is confined to a single measure of the effectiveness of county budgeting, namely, the degree to which the counties are able to live within their available resources. "The fact that 83 percent of the current or operating funds lived within their available resources in 1935 is some indication that county officials are applying budgeting principles to government. The further fact that in 26 counties selected from the 60, the good results obtained in 1935 were continued and improved upon during the 4-yr. period 1936-1939 indicates that the gains of the single year 1935 were not lost as time went on."

Farm rental arrangements in Georgia, J. C. ELROD, D. E. YOUNG, and W. T. FULLILOVE. (Coop. U. S. D. A.). (*Georgia Sta. Bul.* 220 (1942), pp. 50, fig. 1).—Seeking ways to increase food production during the war, prevailing renting practices among farmers of the State were studied. In 1930, 75 percent of all tenant farms produced cotton, whereas only 50 percent of owner-operated farms grew cotton. In contrast, only 29 percent of all dairy farms and 24 percent of all livestock farms were operated by tenants. Cash renting increased from 17 percent of all renters in 1920 to 41 percent in 1940. The cash tenant assumes full management, takes all risks, and pays a fixed cash rental. Under standing renting agreements the landlord furnishes the land, buildings, fences, repairs, fuel wood, and taxes, while a tenant does everything else and retains all the farm income, except a fixed quantity of cash crops which serve as rent. The tenant manages the farm and runs all risks of operating capital and changes in crop yields. Share renting and sharecropping arrangements are also discussed, and suggested rental agreements are included.

Labor, power, and machinery on small farms in Ohio, F. L. MORISON and R. V. BAUMANN. (Coop. U. S. D. A.). (*Ohio Sta. Bul.* 628 (1942), pp. [1]+38, fig. 1).—Labor, horses, tractors, and equipment are surveyed. Also included are discussions of total investment in power and machinery; total cost of labor, power, and machinery; a comparison of matched farms; and further considerations in adjusting power to farm needs. The conclusions reached are that farmers can operate small farms with one-plow or second-hand tractors as cheaply as with horses. Those who have tractors find many opportunities for additional income. Field work can be done more quickly, and more off-farm work can be done for extra cash income. Crops can be cared for at optimum time, and more livestock can be kept. On most small farms the long-time average costs of operating with a tractor are no greater than those of operating with horses. Tractor farms, however, call for a larger investment and cash outlays for fuel, whereas farmers using horses can produce their own horse feed.

Forecast of seasonal labor requirements for California crops, 1942 (as of April 20, 1942), R. L. ADAMS (*California Sta.*, 1942, pp. [1]+14).—Tables are included showing as of May 1, 1942, the assumed acreages and yields of the most commercially important California field, fruit, and truck crops and by months the man-days of labor and number of workers required for each crop. "The need for seasonal labor in California during 1942 is forecasted as a grand total of 26,110,494 man-days."

Sugar beet costs and management in irrigated sections of western Nebraska, G. H. LAMBRECHT and W. L. RUDEN (*Nebraska Sta. Bul.* 341 (1942), pp. 20, figs. 4).—Two hundred and eighty-six records were obtained from 268 growers for the 1941 crop year as to number of hours of man and horse work, equipment required for each operation, quantity and value of materials used, type and size of equipment, etc. Eighty-four farmers gave detailed information as to the cost of operating equipment. No estimates were obtained for hand work done by contract. An analysis is made of the costs of production and harvesting of sugar beets. The effects of quality of land and of management on costs, the compensation for management and risk, and the possibilities of reducing costs are discussed.

The average cost of production was \$71.89 per acre, or \$5.45 per ton. Hand labor comprised 27 percent of the total cost; other man labor, 21; use of horses, tractors, trucks, and equipment, 16; fertilizers, perquisits provided for laborers, and other miscellaneous expenses, 11; and use of land, 25 percent. The average cost of production and harvesting was \$4.26 per ton on the best

lands with good crop management and \$9.81 with an unfavorable combination of poor soil and management. The average cost per ton was \$4.44 with yields of 23 tons per acre and \$9 with yields of 10 tons.

Cost of production and grove organization studies of Florida citrus, Z. SAVAGE and C. V. NOBLE (*Florida Sta. Rpt. 1941, pp. 35, 36*).—A table shows for midseason orange groves, 18 to 20 yr. of age, for the period 1932-37 and by years, 1937-38 to 1939-40, the costs by items; total costs, returns, and profits or loss per acre; costs, returns, and profits or loss per box; and pounds of fertilizer and soil amendments per acre and per tree.

Poultry costs and profits, R. H. WILCOX and L. E. CARD (*Illinois Sta. Bul. 486 (1942), pp. 32, figs. 12*).—The authors discuss factors affecting the success of general farm and semicommercial poultry flocks, 1932-37.

The cost of production of eggs and pullets in southern Arizona, H. EMBLETON (*Arizona Sta. Bul. 183 (1942), pp. [2]+45, figs. 10*).—Records for 51 farms immediately surrounding Tucson, Ariz., were obtained for the year 1932. Forty-four of the records were used in the analysis of the cost of producing eggs and 37 for the cost of producing pullets. The expenditures, receipts, and cost of producing eggs are discussed. An analysis is made of the effects of annual egg production per hen, size of flock, price of eggs, labor efficiency, mortality, and other factors on the cost of egg production and of number of pullets, source of chicks, quality of pullets, and other factors on the cost of producing pullets. The costs of producing eggs are compared with the findings in the studies in other States.

The average cost per dozen of producing eggs was 25.4 ct., and the average price received was 23.6 ct. The average cash cost of producing eggs was 17.7 ct. The average total cost per dozen decreased from 52.4 ct. on farms with an average annual production per hen of 100 eggs or less to 19.3 ct. with 161 eggs or more; from 34.2 ct. with flocks of 199 or fewer hens to 20.7 ct. with flocks of 1,200 or more hens; from 33.4 to 21 ct. as the number of birds handled per man increased from 899 or less to 2,000 or more; and from 25.7 to 30.3 ct. as mortality increased from 9 percent or less to 40 percent or more.

The net income per farm increased from -\$219 where eggs were sold at 22 ct. or less per dozen to \$63 where sold at 26 ct. or more. The average total cost of producing pullets after deducting receipts from the sale of cockerels and cull pullets was 98.3 ct. per pullet, and the cash cost was 61.5 ct. The total cost decreased from \$1.20 on the farms raising less than 200 pullets to 95 ct. on those raising 600 pullets or more. The cost with chicks from the home flock was 88 ct., with chicks purchased locally \$1.02, and with chicks purchased outside the State \$1.03.

Reserves against short-season losses, W. E. PAULSON. (Tex. Expt. Sta.). (*U. S. Dept. Agr. Farm Credit Admin., News Farmer Coops., 8 (1941), No. 1, pp. 5-6, 31; abn. in Texas Sta. Cir. 96 (1942), p. 21*).—A plan is suggested by which the losses in gin operations of cooperative cotton gins in the high and low plains area in Texas in short crop years can be apportioned against the profits in good crop years.

Rough rice marketing in Louisiana, C. A. BOONSTRA (*Louisiana Sta. Bul. 340 (1942), pp. 39, figs. 10*).—The production of rice in Louisiana; the price trends for rough rice, long run, by varieties and grades, and seasons; the public and farm facilities for storage; the problems in rice milling; cooperative marketing; and the principal requirements of a suitable marketing structure from the farmer's point of view are discussed.

"There is no central market or generally accepted trade quotation on the price of rough rice, since each sale is an individual bargain between the pro-

ducer and processor. . . . Since 1931 the average monthly spread between the price of milled Fancy Blue Rose at New Orleans and the average farm price of rough rice in Louisiana has varied from 1 ct. in 1932 to 3.1 ct. under the processing tax of 1935 and to 2.1 ct. in recent years. There is a strong tendency for the monthly spread to fluctuate around 1.5 ct. a pound when the milled rice wholesale price is 3 ct. a pound, narrowing whenever milled rice is lower than 3 ct. and increasing when milled rice rises above this level." The price per pound of rough rice received by farmers averaged about 50 percent of the wholesale price of fancy milled rice. "Blue Rose and Early Prolific prices are the basis of the price structure and define the general price trend, with Early Prolific generally about 20 to 30 ct. under Blue Rose in the wholesale market." In selected periods of stable market situations since 1930, premiums and discounts for varying qualities of rough rice usually ranged up to 10 percent from the average price paid. "During the past 20 yr. a farmer who stored rice each year would have sold at a higher average price than a farmer selling each year in October. General conclusions from these data are that October and December are the weakest price periods during the active marketing year and that November is usually a favorable month in which to sell. As a general rule, prices are as favorable in November as can be expected at any time during the year." About 50 percent of the rice crop in Louisiana, Texas, and Arkansas is sold by farmers during the months of harvest, August through November. Most of the balance is stored in public warehouses. "The most common charge made by bonded warehouses in Louisiana during 1940-41 was 7 ct. per bag the first month, 5 ct. the second, and 3 ct. the third month or fraction thereof, with 15 ct. a bag being the maximum charge for the season." It is estimated that less than 5 percent of the rice farmers owned facilities for storage. Costs of maintenance of farm storage are very low, and a saving of 10 ct. per bag in the cost of storage of 3,000 bags would soon pay for the materials and give a substantial return for labor in constructing farm storage facilities. "The most permanent, and perhaps most effective, market improvements so far achieved in the rice industry have resulted from cooperative marketing associations among rice farmers. . . . The principal requirements of a suitable marketing structure, from a farmer's point of view, are these: (1) That necessary services be performed as efficiently and cheaply as possible, (2) that the farmers know their product and market situation sufficiently well and have financial support sufficiently strong to place them in an adequate bargaining position, and (3) that competition be enforced among the business enterprises through which the product moves to the consumer. Present rough rice marketing practice indicates that these requirements would be better satisfied, respectively, if (1) bulk handling and centralized selling were used to reduce necessary costs for storage, transportation, handling, and assembling, (2) market news service, rough rice grade knowledge, and independent credit standing were utilized by all farmers to increase their bargaining strength, and (3) competition among millers and buyers were enforced by farm organizations constantly on guard against monopolistic practices wherever they might occur."

Organización del sistema de mercadeo y costos de distribución de legumbres y hortalizas en las ciudades de San Juan y Río Piedras [Organization of the system of marketing and cost of distribution of vegetables in the cities of San Juan and Río Piedras], S. DÍAZ PACHECO and J. R. NOGUERA (*Agr. Expt. [Puerto Rico Univ. Sta.], 2 (1942), No. 2, pp. 6-7*).—The authors call attention to the volume of business and of needed action to make the distribution of farm produce efficient and to keep within the necessities created by the war.

Importancia del uso de camiones en la transportación de legumbres y hortalizas [Importance of the use of trucks in the transportation of vegetables], S. DÍAZ PACHECO and J. R. NOGUERA (*Agr. Expt. [Puerto Rico Univ. Sta.]*, 2 (1942), No. 2, p. 5).—The authors call attention to the notable reduction in transportation facilities which has affected the supply of country produce in the more important markets of the island. A survey of 53 owners showed that the total cost per mile run in the transportation of farm produce (vegetables and starchy foodstuffs) amounted to 14.45 ct. The cost of hauling a ton a mile was about 6.92 ct. The cost per ton-mile was reduced considerably by an increase in the size of the load and with the increase of the total miles run. The authors point out certain problems which are necessary to be solved to assure regular flow of produce to market, lower costs of hauling, and the removal of other deficiencies.

Livestock marketing in North Dakota, W. L. ETTESSVOLD. (Coop. U. S. D. A.). (*North Dakota Sta. Bul.* 31½ (1942), pp. 37, figs. 17).—This study is a part of a regional study made by 14 States in the Corn Belt and adjacent area. It is based on 497 questionnaires returned by farmers throughout the State and 343 interviews with farmers in 26 areas selected at random in the different type-of-farming areas and on schedules obtained from 12 auctions, 25 local cooperative shipping associations, 43 local livestock dealers, 7 local markets or concentration yards, 3 packing plants, and 31 retail meat dealers who slaughter. The types of market agencies, markets used by farmers in selling and purchasing livestock, size of lots bought and sold by farmers, operations of markets and market agencies, the transportation of livestock, the areas served by market agencies, etc., are discussed.

Thirty-nine percent of the cattle, 37 percent of the hogs, and 57 percent of the sheep sold by farmers were sold at terminal public markets. Twenty-five percent of the cattle were sold to local dealers and local markets, and 14 percent to packing plants. Nineteen percent of the hogs and 11 percent of the sheep, respectively, were sold to local dealers and local markets, and 21 and 15 percent, respectively, to packing plants. The number of livestock purchased by farmers in relation to the number sold was comparatively small. The average size of sales by farmers was cattle about 5 head, calves 2, hogs 9, and sheep 34 head. "Thirty percent of the cattle were moved from farms in farmers' own trucks, 41 percent by trucks hired by the farmer, and 29 percent by the buyer. The farmer hauled somewhat more of the calves, hogs, and sheep in his own trucks, while less was hauled from farms by the buyer." "There is much variation in the areas from which the various agencies draw livestock. The retail meat dealers have the smallest territory, followed by the local cooperative associations and local dealers. The territory of the auctions and local markets extends past the local community, while packing plants received from one-half to two-thirds of their livestock from areas more than 50 miles from the plant."

Studies in Vermont dairy farming.—XII, Dairy farm management in the Champlain Valley and its relation to the price level, S. W. WILLIAMS (*Vermont Sta. Bul.* 479 (1941), pp. 276, figs. 48).—Continuing the series (*E. S. R.*, 80, p. 551) this bulletin is a thoroughgoing analysis of dairy farming in Vermont for the years 1926-27 and 1932-33. Included are discussions of dairy-herd costs and returns and factors affecting incomes, such as type of milk market, size of business, production per cow, crop yields, labor and capital efficiency, size of miscellaneous farm expenses, choice and combination of enterprises, minor factors, combination of important factors, adjustments in periods of unfavorable prices, and standards for Champlain Valley farms.

Elasticity of supply of milk from Vermont plants.—III, Forecasting the milk supply, S. M. JOHNSON (*Vermont Sta. Bul.* 480 (1942), pp. 116, figs. 18).—

In continuation of the series previously noted (E. S. R., 79, p. 124), part 1 of this bulletin is a study of factors related to or affecting receipts of milk and cream at all licensed plants in Vermont. Part 2 is a similar analysis of factors related to receipts per patron at the plant of the Milton Cooperative Dairy Corporation. The bulletin examines and evaluates a number of methods of estimating probable receipts 3 mo. to a year in advance.

"Two different types of data, or a combination of them, may be used as bases for prediction. These are (1) data on how changes in production are brought about, and (2) data on why they are brought about.

"Of the first type, most valuable for purposes of prediction are data on changes in cattle numbers. The number of milk cows can be predicted with considerable accuracy a year in advance, from data on the number of 1- to 2-year-old helpers on hand, and on recent slaughter and interstate shipments of cows. The rate at which grain is being fed is highly correlated with current, but not with future, production, and is of little or no value as a basis for prediction of receipts.

"Of the second type of data, of things which influence farmers to change the numbers of cows milked or feeding practices, and so to change the amount of milk produced and delivered to plants, the relation between milk prices and grain prices, the milk-feed price ratio, has proven to be most closely related to subsequent production, and most useful for purposes of prediction of supply.

"Of the various forms and combinations of factors examined in this attempt to develop a technique for accurate forecasting of the total market supply of milk in a producing area, the group which gave the best results . . . included factors of both types."

Efficiency of milk marketing in Connecticut, I-III ([*Connecticut*] *Storrs Sta. Buls.* 237 (1942), pp. 53, figs. 10; 238 (1942), pp. 29, figs. 2; 239 (1942), pp. 53, figs. 14).—Three papers are presented.

I. Supply and price interrelationships for fluid milk markets, D. O. Hammerberg, L. W. Parker, and R. G. Bressler, Jr.—It was found possible to allocate producing areas to milk markets in a manner that would minimize the cost of moving milk from farms to markets. More efficient transportation and assembly of milk in the revised Connecticut milksheds would result in an average reduction in costs of about 2 ct. per hundredweight for the wholesale milk production of the State. An additional savings of about 1 ct. could be had by other economies—more country separating plants and the better utilization of skim milk. Transportation savings from the revision of milksheds and the delineation of milk separating plant areas would average about 3 ct. per hundredweight. This is equivalent to increased returns of \$100,000 per year to the wholesale milk producers of the 14 markets considered. With efficient truck organization the economies that would result from the allocation of producing areas would be even greater.

II. The transportation of milk, D. O. Hammerberg and W. G. Sullivan.—Recognizing the importance of milk transportation, the station inaugurated studies to describe the operation of the transportation system, the rates charged for transportation, and the savings resulting from possible reorganization of existing systems. Maps were prepared indicating the organization of each route serving the major Connecticut markets, the location of the producers served, and the location of the dealers' plants. It was found that the organization of milk transportation involved many inefficiencies, the charges made for transportation services do not reflect the costs of performing the services, and monopoly situations frequently stem from the sale of milk and these have often been exploited through transportation charges significantly higher than those occurring where monopolistic forces are not important. The milk trucking system of the State has been characterized by a preponderance of

small trucks, excess truck capacity, and extensive overlapping and duplication of routes. The rates charged for transportation failed to follow any consistent relationships with the cost elements involved, such as length of haul, size of truck and of load, and type of roads traveled. Milk trucking operations in Connecticut are carried on under noncompetitive conditions. Dealers' control of transportation by virtue of their positions as purchasers of the milk apparently leads not only to excessive costs and inefficiencies but to monopolistic profits. In 1936 dealer-haulers charged an average of 9 ct. per hundredweight more than independent haulers on routes similar in distance and volume. Recommendations are made for the improvement of the transportation system.

III. *Economics of the assembly of milk*, R. G. Bressler, Jr., and D. O. Hammerberg.—The effects of such factors as length of route and size of truck and of load on costs of operating milk collection routes were determined. The conclusion was reached that the existing system of milk collection is not only inefficient but is exacting excessive profits from milk producers. With efficient organization the payments for the assembly of milk could be reduced about one-third. This would mean an increase in the annual incomes of the wholesale milk producers in the State of approximately \$250,000. To a farmer having 25 milking cows the savings would average about \$125 annually, or an increase of about 9 percent in the net farm income or 14 percent in the labor income that he would have earned in recent years.

Frozen food locker plants in South Dakota, W. P. COTTON and F. U. FENN (*South Dakota Sta. Bul. 360 (1942), pp. 28, figs. 12*).—"The objectives of this study were to determine the extent of the development of locker plants in South Dakota, to ascertain the present practices in the operation and utilization of these plants, and to determine the influence of the use of locker plants on the general level of living of the patrons." The basic data were obtained (1) from questionnaires sent to the managers of the plants, covering the development, use, services rendered, charges, products stored, type of patronage, etc.; (2) from questionnaires obtained from 124 patrons of 21 plants, covering the use of locker plants, benefits derived, and comments relative to the operation of the plants; (3) 30-day records of the butchers of 13 plants as to species, class, weight, grade, market price, and live value relative to carcass value of each animal killed; and (4) a detailed survey of a limited number of representative plants. The ownership, business association, and patronage of the plants are described. An analysis is made of the extent of storage and source of various products, locker rental rates and services rendered, and profitability of the plants. The facilities, operating practices, plant investment, and financial operation of a limited number of plants studied in detail are analyzed. The kind and quality of meat stored and savings and benefit accruing to locker patrons are discussed.

Status and trend of agricultural cooperation in Maryland, P. R. POTTER-BERGER, J. R. IVES, and S. H. DEVAULT (*Maryland Sta. Bul. 441 (1941), pp. 267-324, figs. 14*).—"The objectives of this study were "to show the extent and character of farmer cooperatives, that is, the number, type, and location of associations, kind of commodities handled, total volume of business done, number of members and patrons, operation practices, etc.; to develop briefly the history of cooperation and to study the influences shaping cooperative development; to emphasize the points of weakness and strength in the operation of Maryland associations, indicating the causes of past failures and the reasons for successful operation; and to obtain information for those persons interested in cooperation and particularly for agricultural leaders who are fostering the cooperative movement in the State." Data were obtained from a questionnaire and interviews with managers of cooperatives and from agricultural leaders, county agents'

annual reports, and the U. S. D. A. Farm Credit Administration. Not only were contacts made with active associations, but as much information as possible was obtained regarding inactive or preexisting associations. The development and present status of the cooperative associations of the State—number, type, membership, patrons, volume of business, and financial growth—are discussed. The cooperative marketing of different farm products is described, with charts showing the total cash farm income from the different products and the value of the products marketed cooperatively by years, 1930-39. The total value of farm supplies used, the local and regional purchasing cooperatives, the value of supplies purchased cooperatively, the farm service organizations, and the federally sponsored cooperatives are described. The cooperative aspects and business operations of the associations (except out-of-State cooperatives) qualifying under the Capper-Volstead Act are analyzed in sections on business and cooperative organizations, methods of financing, measures of financial conditions, and operating practices. Suggestions and recommendations are made for furthering the cooperative movement in the State.

The percentages of the total cooperative business accounted for by marketing, purchasing, and service cooperatives were 84.4, 14.8, and 0.4, respectively. In 1939 farm products valued at approximately \$13,504,500, 19.9 percent of the total farm income, were marketed cooperatively, and the purchasing cooperatives did \$3,884,700 worth of business. The proportion of the total cash farm income accounted for by cooperative sales of various commodities for 1939 was as follows: Milk and milk products, 54.7 percent; poultry and eggs, 2; grain, seed, and hay, 5.1; tobacco, 26.9; truck crops and canning crops, 12.9; fruit, 3.8; and wool, 17.3 percent. Feed accounted for about 51.4 percent of the total purchases; fertilizer, 25.7; seed, 10.1; and miscellaneous supplies, the remaining 12.8 percent. The total liabilities of all associations in 1939 were slightly more than two-thirds of the net worth. Accounts payable were nearly 40 percent of the total liabilities. More than 50 percent of the loans were short term, and most of them were commodity loans. "Almost one-third of the associations analyzed had a current ratio of less than the 2:1 ratio which is considered desirable. About 60 percent of the associations had better than a ratio of 60 ct. total net worth for every \$1 of total assets, which is considered a desirable member's equity. The reserve ratio used was the ratio of total surplus and reserves to business done. Slightly more than one-half of the associations have accumulated reserves of less than 10 percent of their business. In 1939, the operating expense was less than 10 percent of total sales for 23 of the 36 associations and less than 5 percent for 18 of the . . . associations."

Fruit and vegetable cooperatives in Michigan, G. N. Morris (*Michigan Sta. Spec. Bul. 317 (1942), pp. 98, figs. 8*).—This bulletin is one of a series (E. S. R., 79, p. 555) designed to bring the previous study (E. S. R., 60, p. 187) of cooperative associations in Michigan up to date. It includes the decade 1929-38. It is based chiefly on an analysis of data for 20 cooperatives engaged primarily in marketing fruits, 6 marketing vegetable or truck crops, and 6 concerned with vegetable or fruit processing. Potato marketing associations are not included. The major part of the data was obtained from personal interviews with managers of the cooperative associations and examination of the financial and other records of the associations. The history of cooperative fruit and vegetable marketing cooperatives in the State is described. An analysis is made of the operating methods, cooperative standards and corporate structure, capital structure and financial ratios, earnings, management problems, the comparative efficiency of the cooperatives, etc. Appendixes include a sample contract for a cooperative association, a sample contract for a cooperative cannery, score cards for cooperative management, and a summary of the cooperative standards.

"The 10 principal conclusions from the study may be stated very briefly as follows. There must be (1) a genuine need for the cooperative, (2) an adequate volume of business, preferably in excess of \$100,000 per year, (3) efficient operation, (4) an effective membership relations program, (5) a minimum of overlapping in the territories served by different associations marketing the same commodities, (6) some expansion of facilities to serve a larger membership. There has been (7) a gradual trend toward more general use of contracts between members and the association, and (8) a more general use of management ratios as a guide to the management is desirable, but should not be overrated. (9) A plan of some kind to permit a more frequent and thorough exchange of plans and ideas among the managements of the cooperatives seems to promise worth-while results. Finally, (10) if a federated or centralized type of central marketing exchange is again attempted in Michigan, the locals will be uninterested unless convinced in advance that the shortcomings which developed in the past are unlikely to occur in the contemplated one."

A survey of the cooperative marketing of eggs in Michigan, A. HOWLAND. (Coop. U. S. D. A.). (*Michigan Sta. Quart. Bul.*, 24 (1942), No. 4, pp. 326-337).—This article is based largely on a survey made in June 1939 to ascertain the cooperative associations then handling eggs or poultry, the associations which had discontinued the handling of eggs or poultry, and those that were interested in a program to handle such products. An analysis is made of the data from 24 of the 38 associations that handled poultry and eggs. The types of associations handling these products, the reasons for the products being handled, the production conditions affecting marketing programs, the financial risks in egg marketing, and the accomplishments achieved by cooperative marketing of eggs and poultry are briefly discussed. The egg procurement practices and the egg-grading programs of the associations are discussed, with tables showing data as to frequency of deliveries of eggs; egg-hauling practices; the basis of purchase, frequency of payments, and the waiting period for payment for eggs; and the egg quality production and preservation factors emphasized.

In June 1939 only 38 cooperative associations were handling eggs and poultry, 32 had discontinued the handling of such products, and 54 were interested in undertaking an egg and poultry marketing program. Only 1 association was organized primarily to handle eggs and poultry. Associations handling farm supplies and creameries handled the larger volumes of eggs and poultry. About 100 cases of eggs per week are the minimum volume required for a successful Federal-State egg-grading station. No association used any form of compulsion or marketing agreement to influence frequent deliveries of eggs, but the managers of 7 associations placed emphasis on frequent deliveries. Usually the associations did not collect eggs from the farms. Protection of eggs collected by truck against heat and cold was practiced by only 2 of the 7 associations that collected eggs. "All except 1 of the associations purchase eggs on the basis of a definite paying price upon the date of receipt. This single exception operates upon a weekly pool basis." Only 5 associations paid price differentials based on shell color of eggs. Only 2 associations recognized shell texture in their grading operations. Cleanliness was a factor considered by 7 associations, and 7 associations also used a price differential based on internal quality of the eggs.

Cooperative wool marketing in Kentucky, C. D. PHILLIPS and C. M. AULL. (Coop. U. S. D. A.). (*Kentucky Sta. Bul.* 424 (1942), pp. 24, figs. 3).—The organization and operation of the six local wool pools of the State and of the Kentucky Wool Growers' Association are described.

Some 2,500 farmers, 8.3 percent of all Kentucky wool growers, sold wool through the six local cooperative pools in 1940. The seven cooperative associations handled about 632,000 lb. of wool. 11 percent of the wool clip, in 1940.

Some of the local associations secured as much as 6 ct. per pound above the State average, while others sold wool at less than the State average. The cost of handling wool in 1940 by the local associations ranged from 0.3 to 2.3 percent of the value of the wool handled. The cost of handling by the State association was 8.8 percent.

Farm parity prices and the war, M. GUIN (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 7, p. 1).—A brief discussion.

Wheat and flax prices received by farmers in north central and north eastern South Dakota, 1890–1940, W. H. PETERSON (*South Dakota Sta. Cir.* 37 (1942), pp. 16, figs. 7).—"This circular is the first of a series intended to present in a simple and objective manner the prices farmers have received for their more important products over a 50-yr. period, the crop years of 1890 through 1939. An interpretation of the significance of the price data will also be presented." The price data for wheat and for flax for the years 1890–1939 are analyzed to show the variability by counties, by years, and by decades. The trends and the seasonality of the prices and the factors affecting the prices are discussed.

During the period wheat prices fluctuated from a low annual average of 30 ct. to a high of \$2.50 per bushel. The average annual flax prices ranged from less than 55 ct. to more than \$4.32 per bushel. "In 7 out of every 10 yr. studied, the South Dakota price of wheat has been less than \$1; during one-third of this period it has been less than 70 ct. The price of flax has fluctuated mainly between the limits of \$1 and \$2, but it was less than \$1 in 20 percent of the years and over \$2 in 25 percent of the years." The trends of both wheat and flax prices were upward during the 50 yr., but the rise was not so pronounced or sustained as that for industrial price levels. "In the case of neither wheat nor flax does the seasonal price appear large enough to justify increased storage operations by farmers if this involves building additional storage capacity." There was no appreciable difference in the earning capacity of wheat and flax in the areas of the State where both were grown.

Statistical analysis of the annual average f. o. b. prices of canned asparagus, 1925–26 to 1940–41, G. M. KUZNETS and H. R. WELLMAN (*California Sta. Mimeog. Rpt.* 80 (1942), pp. [1]+7, fig. 1).—This report presents the results of an analysis of the major factors influencing the average f. o. b. prices received for canned asparagus by canners in California from 1925–26 through 1940–41.

Deciduous fruit statistics as of January 1942, S. W. SHEAR (*California Sta. Mimeog. Rpt.* 79 (1942), pp. [2]+III+113).—This fourth compendium covers the same general field as that for January 1941 (*E. S. R.*, 85, p. 688).

El precio al por menor de los alimentos en Puerto Rico sigue aumentando en proporción mayor que en meses anteriores [The retail price of foodstuffs in Puerto Rico continues rising in greater proportion than in previous months] **S. L. DESCARTES** (*Agr. Eapt. [Puerto Rico Univ. Sta.]*, 2 (1942), No. 2, p. 8).—The author calls attention to increases in the retail price of foodstuffs in Puerto Rico in the period March 17 to April 14, 1942 (July 1939=100).

Effects of currency depreciation on prices, production, and foreign trade, 1929 to 1937, O. VAN DER MERWE ([*New York*] *Cornell Sta. Mem.* 242 (1942), pp. 47, figs. 6).—The author examines the effects of exchange depreciation on foreign trade. During the early years of the period 1929–37 the effects of currency devaluation on the value of the foreign trade of countries were largely obscured by price movements due to the depression. The gold value of both imports and exports declined more in the depreciated-currency than

in the non-depreciated-currency countries. With the growing complexity of modern economic organization, rigidities in the economic structure have become more and more important. The vital importance of balance in the internal price structure of countries has been brought out strikingly by the depression. The attempts at relieving depression and correcting price disparities and the role played by currency depreciation would indicate that the problem of managed currencies may become of even greater importance in the future.

Topics discussed included the effects of currency depreciation on foreign trade, business activity, and prices, and internal and external price relationships.

RURAL SOCIOLOGY

[**Rural life influences in Kentucky**] (*Kentucky Sta. Rpt. 1941, pp. 41-42*).—The studies reported are on the growth of Kentucky population, 1860-1940; community organization; and land-use trends in the eastern highland region, 1929-39.

[**Population questions in North Dakota**] (*North Dakota Sta. Bimq. Bul., 4 (1942), No. 6, pp. 3-21, figs. 2*).—The following articles are discussed: The Farm Population of North Dakota, by H. L. Walster (pp. 3-4); Farm Population Continues to Decrease, by J. P. Greenlaw, A. J. Kovash, and F. B. Daniel (pp. 4-7) (coop. U. S. D. A.); Fewer Farm People Again in 1940, by J. P. Greenlaw and R. Novak (pp. 7-11); "Sizing Up" the Small Town, by J. P. Greenlaw and D. M. Richardson (pp. 11, 14-17); and The Population of North Dakota, by H. L. Walster (pp. 12-13, 18-21).

Population redistribution in Louisiana, H. L. HIRT and T. L. SMITH. (La. State Univ.). (*Social Forces, 20 (1942), No. 4, pp. 437-444, figs. 4*).—"As is the case throughout most of the United States, the long-continued urbanization of the State is one of the most important changes in the population of Louisiana . . . During the 50-yr. period from 1890 to 1940 the urban population increased two and one-half times, from 283,845 to 980,439; in the meantime the rural population increased only 66 percent, from 834,743 to 1,383,441. Whereas in 1890 the urban population of the State comprised only 25.4 percent of the total, by 1940 it constituted 41.5 percent of all persons in the State. In the decade ending with 1940 the growth of the urban population was 17.6 percent as compared with only 9.1 percent for the rural population. . . . Population changes in the unincorporated territory of the State appear to bear an important relationship to the type of farming practiced. In the past decade, population gains were more pronounced in the self-sufficing cotton area of Washington and St. Helena Parishes and the Gulf coast dairy, truck, and fruit area [near] New Orleans. . . . The sugar parishes, also, experienced sufficient gains. Of all the wards in which farmers are primarily engaged in the production of sugarcane, three-fifths exhibited substantial increases in population outside of incorporated centers. The loss of open country population seems to have been most pronounced in the strawberry area and in the Red River delta. . . . This study showed that plantation sections lost heavily through migration, but that this loss could be more offset by the inward surge of families to take over farms on nearby cut-over new ground. . . . Decreases of population outside incorporated centers throughout the State were most frequent where Negroes were most numerous."

Statistical supplement to Volume and Characteristics of Migration to Arizona, 1930-39 (Arizona Agricultural Experiment Station General Bulletin No. 176), V. FULLER and E. D. TETREAU. (Coop. Ariz. Expt. Sta.

et al.). (*U. S. Dept. Agr., Bur. Agr. Econ., 1941, pp. 24*).—This is a presentation of survey methods and statistical tables, supplementing the bulletin previously noted (E. S. R., 87, p. 135).

Land settlement in the Willamette Valley, with special reference to Benton County, Oregon. V. W. BAKER and D. C. MUMFORD. (Coop. U. S. D. A.). (*Oregon Sta. Bul. 407 (1942), pp. 46, figs. 20*).—The study indicated that the "Food for Freedom Program" will probably result in increased production in the area of those agricultural products deemed necessary to feed the armies of the democracies. A back-to-the-land movement may be expected after the war. Opportunities for additional agricultural settlement in the Willamette Valley are rather limited, but there are greater opportunities for part-time farming than for off-the-farm employment. Regardless of the type of migration which takes place to Benton County and the Willamette Valley or the extent to which forces shape and change the pattern of settlement, it is deemed desirable to give some measure of direction and control to the movement.

The relation of the rural church to other rural organizations. H. HOFFSOMMER. (La. State Univ.). (*Social Forces, 20 (1941), No. 2, pp. 224-232*).—The author concludes that "the relation of the rural church to other social organizations and agencies may best be shown by considering the spatial relation of the church to other agencies and . . . the nature of the social interaction between the church and these other agencies."

The country weekly: A source of research data. C. F. REUSS. (Wash. Expt. Sta.). (*Social Forces, 20 (1941), No. 2, pp. 238-243*).—"An immense store of sociologically significant materials of particular interest to rural sociologists is contained in the files of American small town weekly newspapers. . . . This article describes some aspects of the rural community in operation as revealed by a detailed analysis of the news and advertising content of a representative sample of weekly newspapers. . . . One of the most interesting findings, and perhaps the most significant, concerns the place of the individual in rural society. It was discovered that the percentage of the total news space devoted to chronicling the activities of people and their personal affairs increased steadily with increasing size of town until the publication center attained a population of 2,500. Once that point was reached, however, the percentage of personal news began to decrease as the towns increased in size. . . . These related tendencies appear to warrant the conclusion that in the distinctively rural community interest centers in the individual per se, whereas in the distinctively urban environment the individual is of interest only insofar as he represents a group, a profession, or a class. . . . Through this analysis of newspaper content a fundamental difference between the primary group and the secondary group, between the rural community and the urban, has been emphasized. . . . Although by and large the proportion of both farm news and advertising decreased as the town became larger and thus farther distant from the soil, towns of 500-999 population provided a notable exception to the rule. Papers published in such centers contained more than twice as much farm news and advertising in proportion to total space as the next highest group of papers. . . . The volume of medicine and health advertising was of progressively less importance as towns became larger. In the smallest towns of less than 500 population, however, this type of advertising was of greater importance than any other type, exceeding even automotive and food advertisements in volume."

Emerging problems of the aged. P. H. LANDIS. (Wash. State Col.). (*Social Forces, 20 (1942), No. 4, pp. 460-467*).—"No definite place for the aged is made in the productive economic scheme, and they have only recently been cared for as a subsidized economic group. They are given little place in managing

the affairs of the world unless they happen to be vigorous enough to have retained an executive position . . . Since the old tend to be conservative, one would assume that the power of this group tends to exert a conservative influence in the general practices of governmental and economic institutions. . . . In making any adjustment to life the aged are working under the initial handicap of waning physical and mental energy. . . . The power of making quick decisions deteriorates in late maturity; information tends to increase up to the 50's, but its acquisition becomes more difficult . . . There are, of course, many examples of persons of extreme age making notable contributions to society. . . . Senescence, in many cases, is no doubt in part a state of mind. Ill health, economic insecurity, loss of social prestige, the shock of dropping out of the work world, enforced idleness, and other factors . . . may be so emotionally disturbing as to cause the individual to give up the struggle to advance or to be self-maintaining. . . . Even the institutions in which the old person is rooted often prove to be transient. . . . But the adjustments required within rural life cannot compare with the radical personality adjustments that are necessitated when an old person transfers from rural culture to urban culture, as some must do in going to live with children or in entering under the care of some public institution. . . . The old experience a radical transition in institutional participation. . . . More serious still is the frequent necessity of old people having to enter institutions with a regimen which is entirely new. Strangely enough, until very recently the special institutions provided for the aged were based on the assumption that the old person who needed institutionalization was a pathological type. . . . Certain new organizations of a voluntary type have indirectly made their contribution to the happiness of the aged. Undoubtedly, the numerous Townsend Clubs throughout the country have given the old a new focus of interest. . . . Social security programs are so new that it is not yet possible to know all of the adjustments that will be required by their initiation. That they will have far-reaching implications to many phases of American social and economic life is not to be doubted. . . . The aged require more extensive hospitalization, are a more dependent group, and are less productive than other adult groups in the population. . . . The demands of the old are rapidly increasing; their standards of living are rising. . . . It would not be surprising, if the old continue to function as an organized pressure group, to see movements put on foot during this generation to disfranchise those who reach retirement age, in order to protect the interests of other age groups in the population."

Acceptance of approved farming practices among farmers of Dutch descent, C. R. HOFFER (*Michigan Sta. Spec. Bul. 316 (1942), pp. 35, figs. 3*).—This study, based on the circulation in six communities of Dutch and English editions of a station circular on celery growing, supported the hypothesis that the rate and extent of acceptance of approved farm practices constitutes an indication of cultural change regarding agriculture among the celery growers of the State. Growers who read bulletins, attended meetings, and otherwise came in contact with the influences promoting scientific methods, adopted more recommended practices than others, because such contacts had produced the necessary changes or adjustments in their culture.

A sociological analysis of propaganda, C. R. HOFFER. (*Mich. State Col. (Social Forces, 20 (1942), No. 4, pp. 445-448)*).—The author states that "propaganda is the process of influencing attitudes in a veiled manner regarding matters of controversy within a society. . . . Its purpose is to influence attitude in a predetermined way in contradistinction to education designed to develop personality or the dissemination of information which may be designated to

create good will. . . . Since it is veiled and partisan in nature, propaganda retards the formation of intelligent public opinion and thus is a menace to democracy. Publics, however, are becoming increasingly aware of the nature and extent of propaganda and thus its dangers are greatly reduced."

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Workers in subjects pertaining to agriculture in land-grant colleges and experiment stations, 1941-42, B. T. RICHARDSON (*U. S. Dept. Agr., Misc. Pub. 480 (1942), pp. VI+176*).—This is the usual annual list (E. S. R., 85, p. 690) of the workers in agriculture and home economics in the land-grant colleges and experiment stations, the personnel of the Office of Experiment Stations, and the officers and standing and special committees of the Association of Land-Grant Colleges and Universities.

Selected list of American agricultural books (*U. S. Dept. Agr., Libr. List 1 (1942), pp. 29*).—This is a revision (E. S. R., 75, p. 562).

FOODS—HUMAN NUTRITION

Human nutrition [investigations by the Arizona Station] (*Arizona Sta. Rpt. 1941, pp. 69-74*).—This progress report (E. S. R., 85, p. 693) includes summaries of studies, for the most part representing an extension of earlier work, on thiamin (vitamin B₁) metabolism in humans, including the description of a method for judging thiamin nutritional status and an application of the test to college students and rural housewives; thiamin metabolism in rats; the absorption of fluorine by foods cooked in water containing fluorine; and the mineral content of vegetables as related to the soils in which they grow, with data on the range in calcium, phosphorus, and iron content of carrots and lettuce.

[Foods and nutrition studies by the Florida Station] (*Florida Sta. Rpt. 1941, pp. 76-78*).—This progress report summarizes the results of studies, some of them in continuation of work noted earlier (E. S. R., 85, p. 691), by O. D. Abbott, M. R. Overstreet, and R. B. French on human dietary deficiencies in selected counties in Florida, with special reference to nutritional anemia in relation to composition of home-grown foods; by Abbott and French on the chemical composition and nutritive value of Florida honeys and royal jelly; and by French and Abbott on vitamin A activity of foods and on vitamin C in Florida fruits and vegetables.

[Food and nutrition studies of the Massachusetts Station] (*Massachusetts Sta. Bul. 388 (1942), pp. 69-71*).—Progress reports, for the most part representing an extension of earlier work (E. S. R., 85, p. 845), are given on research by H. S. Mitchell and A. W. Wertz on the vitamin requirements of older people; by Mitchell, G. M. Cook, and Wertz on the cause and control of nutritional cataract; and by F. Kinder and Mitchell, with the cooperation of W. S. Mueller, on the nutritive value of the iron of cocoa and iron-fortified cocoa mixtures.

[Food and nutrition studies by the Wyoming Station] (*Wyoming Sta. Rpt. 1941, pp. 21-22*).—This annual report (E. S. R., 85, p. 122) summarizes the progress made in studies on the losses of ascorbic acid in snap beans as affected by methods of handling before and after cooking and canning, on the storage and cooking losses of vitamin C in potatoes, and the reliability of pressure cooker gages, all by E. J. Thiessen, and on the basal metabolism of college men, by E. J. McKittrick.

Meals for many: For school, camp, and community, K. W. HARRIS and M. A. Wood (*N. Y. State Col. Agr., Cornell Ext. Bul. 477 (1942), pp. 320, figs. 62*).—

This publication has been planned to help inexperienced persons prepare and serve foods in large quantity, as for school lunches and camp and community meetings. The authors acknowledge help from resident staff members, students, and extension specialists in the departments of food and nutrition, economics of the household, and institution management of the college of home economics; home demonstration agents; homemakers; and directors of school lunchrooms and of camps. Many of the photographs have been supplied by commercial companies. The wealth of material included in the bulletin is presented under the general headings menus and menu planning; purchasing and using food economically; sanitation; the school lunch; camp-food service; community-meal service; canteen service; teas, buffet meals, and picnics; and food preparation and recipes. Of particular interest is a small section on canteen service in which are given the plans and equipment for a simple mobile kitchen built on a standard 1½-ton reconditioned truck and suited to the preparation and serving of various types of meal from a simple and complete meal for from 100 to 150 persons to a one-dish meal for from 600 to 650 persons.

Meat for thrifty meals, L. M. ALEXANDER and F. W. YEATMAN (*U. S. Dept. Agr., Farmers' Bul. 1908 (1942), pp. 11+46, figs. 19*).—This publication gives suggestions for selecting and cooking the cheaper cuts of beef, pork, lamb, and veal, and offers many recipes under the following classifications: Tender roasts; stuffings for roasts; braised steaks, chops, and pot roasts; stews in variety; ground meat in savory ways; gravies; sauces; quick dishes with leftovers and canned meat; sandwiches—hot or cold; soups and chowders; liver and other meat organs; and salads—hot or cold.

Palatability and histological changes occurring in New York dressed broilers held at 1.7° C. (35° F.), H. L. HANSON, G. F. STEWART, and B. LOWE (Iowa Expt. Sta.). (*Food Res., 7 (1942), No. 2, pp. 148-160, figs. 7*).—The dressed Leghorn broilers were spray cooled. The controls were eviscerated and placed in the oven within from 6 to 40 min. after chilling, and the remaining birds were stored at 35° for 40 min. to 118 hr. before evisceration and cooking. The cooked chicken was scored for aroma, flavor, tenderness, and juiciness, and sections of three leg and two breast muscles were examined histologically. One control bird, held for 118 hr., was used for histological studies of the raw muscle. The first decrease in aroma and flavor scores occurred after 40 hr. of storage. These scores tended in general to decrease with increase in the storage time before cooking. Muscles in rigor when taken from the oven were rubbery and tough. The breast muscles increased rapidly in tenderness until approximately 3 hr. of storage prior to cooking. With longer storage there was a continued gradual, but slight increase in the tenderness. In general thigh muscles were less tender than those from the breast and required about 42 hr. of storage to reach a degree of tenderness comparable to that attained by the breast muscles in 3 hr. The thigh was more juicy than the breast, due possibly to the presence of a greater amount of fat. Juiciness was unaffected by the time of storage.

"The greatest decrease in the desirability of the aroma and flavor of the liver occurred after 20 hours' storage. The aroma scores of the gizzard dropped after the same period of time, but the decrease in flavor of the gizzard occurred after only 3 hours' storage. Tenderness and juiciness of the liver and gizzard were unaffected by the length of the storage time. Microscopic studies of two breast muscles and three thigh muscles showed similar post-mortem changes occurring in each muscle, but the time required for the same degree of change varied considerably for each muscle. The first change was the appearance of the nodes and internodes characteristic of rigor mortis. Following the passing of rigor, there was a thinning of the cell contents at random points

in scattered muscle fibers. Then definite breaks appeared in the fibers. Finally there was a change of the striated to a granular type of structure over a relatively long area of the cooked fiber. These changes appear to be correlated with changes in tenderness of the muscles. The post-mortem changes occurred more slowly in the uncooked than in the cooked fibers."

Representative photomicrographs are presented.

The detection of bacteria in liquid egg-meats during processing, W. L. MALLMANN and E. CHURCHILL. (Mich. Expt. Sta.). (*Ice and Refrig.*, 102 (1942), No. 5, pp. 303-305, fig. 1).—The direct microscopic test described for detecting the incidence of bacteria in liquid eggs was developed as a quick procedure for checking the bacterial content during processing. The method involves the preparation of film slides and the subsequent staining of the dried film of constant thickness with an acid methylene blue stain. The bacterial content of egg meats can be determined at the plant in less than 30 min. after the samples have been collected. It is pointed out that this method is not a substitute for the plating technic, but is for use in control work only. The method was found applicable to whole eggs and yolks but was not satisfactory for egg whites.

Cooking properties of eggs processed in mineral oil, J. A. McINTOSH, R. TANNER, R. J. EVANS, and J. S. CARVER. (Wash. Expt. Sta.). (*U. S. Egg and Poultry Mag.*, 48 (1942), No. 6, pp. 345-347, 383).—The eggs tested were (1) fresh eggs, (2) eggs stored 10 days without processing, (3) eggs stored 5 mo. without processing, (4) eggs processed in mineral oil (for several seconds at 62°-72° F.) immediately after gathering and stored for 3 mo., (5) eggs processed noon and evening of the day gathered and stored for 3 mo., (6) eggs processed the morning after the day of gathering and stored 3 mo., and (7) eggs processed the morning of the third day after gathering and stored 5 mo. The eggs were poached and scored for flavor, texture, color, and appearance, and certain physical measurements were made on the raw eggs.

In cooking qualities and most of the physical measurements the fresh eggs scored highest, and the 10-day-old eggs stored at 40°-50° ranked second in most cases. The eggs processed the second day and stored for 3 mo. approached those stored for 10 days without processing in the matter of cooking quality, appearance when broken, and volume and stability of the beaten whites. Processed eggs when boiled were more difficult to peel than nonprocessed ones. pH determinations indicated that processing tended to retard the decrease in acidity that normally takes place as eggs age. "The results of this study indicate that the best time to process eggs is the day after gathering. Eggs processed immediately, noon and evening of the day gathered, or the third day after gathering were not as good as those processed the day after gathering, but were considerably better than eggs stored 5 mo. without processing."

Frozen eggs, J. G. WOODROOF. (Ga. Expt. Sta.). (*Ice and Refrig.*, 102 (1942), No. 1, pp. 62-64, figs. 4).—The preparation of eggs for freezing, whether for commercial handling or for locker stores, and the storage and utilization of frozen eggs are discussed briefly, and the results of baking tests are reported. In these tests, angel, gold, and butter cakes made with frozen whites, yolks, and whole eggs, respectively, were scored in comparison with similar cakes made with fresh eggs. "It was shown from this study that frozen eggs are highly acceptable for baking cakes. In every case except one the cakes made from frozen eggs scored as high or higher than those made from fresh eggs. It was also shown that frozen whole eggs with 3 percent glycerin gave a smoother, finer, more even grain than either fresh eggs or frozen eggs without the glycerin. From 1 to 3 percent salt in the frozen eggs markedly increased the flavor of gold and butter cakes."

Frozen eggs: Their suitability for cake baking, J. G. WOODROOF. (Ga. Expt. Sta.). (*Bakers Digest*, 16 (1942), No. 7, pp. 134, 139).—Essentially noted above.

Quality in rice, A. SREENIVASAN (*Empire Jour. Expt. Agr.*, 9 (1941), No. 35, pp. 184–194).—This summary paper, based on recent studies of the author and other investigators, is concerned with the changes in the chemical composition of rice due to (1) varietal, cultural, and environmental differences and (2) polishing, parboiling, and cooking; and with the interrelation of composition and nutritive value of rice. Seventy-one references are cited.

Nutritive value of the protein and mineral constituents of rice varieties, A. SREENIVASAN (*Cereal Chem.*, 19 (1942), No. 1, pp. 36–47, figs. 2).—Six varieties of unpolished rice (grown in India) analyzed for protein, ash, P_2O_5 , and CaO content were powdered and autoclaved and used separately with supplements of cod-liver oil and marmite extract in feeding tests with rats. The rice constituted the only source of protein and minerals in the rations. Growth rates were found to be essentially related to the protein and mineral contents of the rations, as indicated by the growth curves and the correlation shown by means of a regression equation. Growth rates, which decreased after about 2 mo., were caused to increase again by supplements of casein given at that stage; the resulting increase in growth was again proportional to the nitrogen and mineral contents of the rices. The weekly average growth rates of the rats increased when a supplement of phosphate-free salt mixture was given, but differences due to varieties were still of the same order. When the protein content was adjusted to the same level in two of the diets by the requisite additions of purified rice protein, it was observed that the growth rate was greater with the variety of rice containing the greater percentage of phosphorus. The significance of the observations in relation to the nutritive values of the protein and mineral constituents of rice varieties and the availability of phytin in rice is discussed.

Nutritive value of the protein and mineral constituents of dry and wet cultivated rices, A. SREENIVASAN and V. SADASIVAN (*Cereal Chem.*, 19 (1942), No. 1, pp. 47–55, figs. 3).—A study was made of the chemical composition (moisture, protein, ether extract, ash, and P_2O_5) and the nutritive value of the protein and mineral constituents of three different rice varieties grown under (1) irrigated transplanted, (2) irrigated broadcast, and (3) dry broadcast conditions. Irrigated rice, irrespective of variety, was found to be richer in protein (9.06–10.77 percent) and ash (1.314–1.474 percent) than dry cultivated rice (7.87–8.35 percent protein; 1.236–1.334 percent ash). Of the irrigated rice, that which was transplanted contained higher percentages of these constituents and a lower percentage of fat than did the broadcast rice.

“In experiments on the growth of young albino rats fed with the different rice samples as the sole source of proteins and minerals, it was found that dry cultivated rice was least nutritious compared to wet cultivated, transplanted rice. Irrigated broadcast rice was intermediate in nutritive value between dry and irrigated, transplanted rices.”

Digestibility and biological value of whole wheat breads as compared with white bread, J. R. MURLIN, M. E. MARSHALL, and C. D. KOCHAKIAN (*Jour. Nutr.*, 22 (1941), No. 6, pp. 573–588, fig. 1).—Ten healthy male subjects averaging 29 yr. of age received 2,914 calories daily, 4.8 percent of these being furnished by protein, 48.6 percent by carbohydrate, and 46.6 percent by fat. Egg as the standard protein furnished 80 percent of the nitrogen for 6-day periods which alternated with like periods on bread as the source of this fraction. Twenty-four-hr. urines were analyzed on the last 4 days and feces (composite) for the full period. The three white breads gave true digestibility values for the proteins of from 98.3 to 99.4 percent and biological values of from 74.6 to 79.8 percent on the basis of 100 percent for egg proteins; digestibilities of the pro-

reins in three whole-wheat (including "peeled wheat") breads ranged from 92.8 to 94.9 percent and biological values from 77.8 to 81.0 percent; corresponding values for a whole-wheat cereal biscuit were 85.2 and 81.6 percent. The higher biological values were associated with those breads made with high vitamin yeast. In certain periods when extra vitamin B complex was eaten with the breads, the biological values of the proteins seemed to be improved.

Apparent digestibility of carbohydrates, fats, and "indigestible residue" in whole wheat and white breads, R. R. SEALOCK, D. H. BASINSKI, and J. R. MURLIN (*Jour. Nutr.*, 22 (1941), No. 6, pp. 589-596, fig. 1).—The plan of the experiment, the composition of the diet, and the breads used were the same as those in the previous study noted above. Total carbohydrate, fat, lignin, hemicellulose, and cellulose were determined in food and feces by methods noted. "The apparent digestibility of carbohydrates varied from 97.6 to 99.8 percent and of fat from 95.7 to 97.4 per cent. No significant difference between the results obtained with white breads and whole-wheat bread was found. It may be concluded that under the conditions of these experiments, in which the diet furnished approximately adequate calories for maintenance of weight of each subject, the higher indigestible residue of the whole-wheat products does not interfere with the digestion and absorption of carbohydrate and fat. The indigestible residue exhibited an apparent digestibility of 29.2 to 76.3 percent. The white breads gave the higher values, 68 to 76 percent, and the whole-wheat products the somewhat lower values of 55 to 62 percent."

Honey and corn syrup for cakes will save sugar for preserving fruit; recipes given, W. E. PYKE (*Colo. Farm Bul. [Colorado Sta.]*, 4 (1942), No. 3, pp. 10-13, fig. 1).—Recipes adapted for high altitude baking of cakes and employing strained honey and corn sirup in place of cane or beet sugar have been built up upon experimental tests in the station altitude laboratory. The cake formulas, deliberately kept on the economy side, are variations of the same basic yellow butter-type cake formula. This formula is given, with indications of adjustments that must be made at various altitudes in the amounts of liquid (milk), eggs, and baking powder, and with indications of the proportions of ingredients to be used in varying the basic recipe to give spice, ginger, chocolate-spice, and devil's food cakes. The method of mixing is also outlined.

Vegetables and fruits in relation to human nutrition in wartime, P. B. MACK ET AL. (*Pa. State Col. Bul.*, 36 (1942), No. 28, pp. [2]+54, figs. 22).—This publication, prepared by the nutrition subcommittee of the advisory victory garden committee of the Pennsylvania State Council of Defense, contains a preface, by A. C. Marts; a brief summary under the title *The Nutritional Ledger* of the findings to date of the Pennsylvania mass studies in human nutrition, showing the principal deficiencies in the diet of various population groups in the State; a discussion of the specific contribution of vegetables and fruits to the diet, with a table of the content of protein, minerals, and vitamins in average servings of common vegetables and a more detailed table condensed from a publication of the Philadelphia Child Health Service of the nutritive value of common vegetables and fruits; papers by W. B. Mack entitled *More Vegetables for the Duration and Afterwards* and *The Victory Garden Program*; and excerpts from various publications of the Ellen H. Richards Institute under the title *How Good Is Our Nutrition?* Suggestions for posters and displays for promoting victory gardens and directions for preserving the victory garden products are included.

Firmness of canned fruits and vegetables (*Kentucky Sta. Rpt.* 1941, pp. 31-32).—This progress report indicates that calcium chloride added in canning, at levels of from 0.05 to 0.09 percent, improved the texture of rhubarb, plums,

and raspberries by increasing the firmness of the canned fruit; the texture of asparagus, gooseberries, or strawberries was not affected.

Preservation of fruits and vegetables by freezing in refrigerated locker plants. H. H. PLAGGE and B. LOWE (*Iowa Sta. Bul. P46, n. ser. (1942), pp. 485-528, figs. 8*).—This bulletin presents information on the selection, preparation, and utilization of fruits and vegetables preserved under frozen food locker systems. The recommendations are based on investigations carried out over a 4-yr. period in which preparation and processing was done on a small scale in a kitchen laboratory to simulate home conditions. The methods described were found to yield frozen products of excellent quality. It is pointed out that the information is not intended as a guide to commercial packing of frozen products, and that the recommendations are applicable most specifically to Iowa-grown fruits and vegetables. The material presented covers equipment for preparing fruits and vegetables for freezing; kinds and varieties of fruits and vegetables for freezing; selection as to maturity, condition, and quality; preparation; packing (with reference to containers and the use of brine, sugar, and sirup); labeling of packed products; freezing; storing; utilization of frozen fruits and vegetables; handling of the frozen products in the home; and cooking the frozen fruits and vegetables with regard to particular uses and the conservation of food nutrients.

Frozen fruit and vegetable research indicates desirable new products for lockers. H. H. PLAGGE and B. LOWE. (*Iowa Expt. Sta.*). (*Ice and Refrig., 102 (1942), No. 6, pp. 357-361, fig. 1*).—Standard recommended varieties of vegetables harvested for the most part at the stage best for table use were used in this study. In preparation the greens were washed, the soybeans shelled by a mechanical hand sheller, and the root vegetables washed, pared, and diced. Except for the beets, which were cooked before paring and dicing, the prepared vegetables were blanched for 2 min. (parsnips 3 min.) in boiling water, cooled immediately, drained, and packed into glass jars (which were then sealed airtight) and frozen rapidly. After 24 hr. in the freezer, the products were transferred to lockers held at 0° F. After from 5 to 10.5 months' storage, the products were cooked and scored by a panel of judges. Of the greens, Swiss chard, beet leaves, New Zealand spinach, kale, and spinach yielded excellent frozen products; mustard and turnip greens were only fair to good in quality, due to being somewhat overgrown when selected. Beets, turnips, and kohlrabi yielded products excellent in appearance, texture, and flavor, and closely resembling the cooked fresh vegetables. The parsnips were rated good, but were somewhat bitter, possibly because of being slightly mature. The soybeans were very satisfactory as to texture, color, and flavor.

Fresh pineapple (Red Spanish variety), as purchased on the Iowa retail market, was packed in 30-, 40-, and 50-percent sirups, in a 3+1 sugar pack, and in water; new hybrid plums, hardy under midwest conditions, were packed in 60-percent sirup and 3+1 sugar. These were frozen and stored, the pineapple being scored after 10 mo. and the plums after 8 mo. The pineapple was found to be one of the best of frozen fruits with respect to preservation of color, texture, flavor, and aroma; the 30- and 40-percent sirup packs were the most desirable as to sweetness. The plums, cooked for 5 min. before judging, retained their rich, tart, fresh flavor and bright color and were considered very desirable.

Microscopic studies of tissue of frozen fruits and vegetables. M. J. COX and M. M. MACMASTERS. (*Ill. Expt. Sta.*). (*Food Res., 7 (1942), No. 2, pp. 135-139, pls. 2, fig. 1*).—A number of products were frozen (1) at about -31° C., the temperature used in many locker plants, and (2) on solid CO₂, at about

—76°. Asparagus frozen by the former method showed a great deal of cellular break-down, while that frozen on solid CO₂ was a very acceptable product. The cell structure of whole strawberries and sliced peaches was much better preserved by freezing on solid CO₂ than by freezing at —31°.

Peaches were also frozen under air, CO₂, or N₂ at 30 lb. pressure in order to increase the amount of gas within the cells. Samples thus frozen showed on the whole no more cell rupture, and in some cases even less, than those not subjected to this treatment. This behavior is interpreted to indicate that dissolved gases which are forced out of solution by freezing are in no way responsible for cell rupture, but that this is brought about entirely by ice crystal formation. The color and texture of the peaches frozen in an atmosphere of N₂ were very well preserved even in the absence of sirup. The fruit frozen under CO₂, although less desirable than that frozen under N₂, was an acceptable product, while that frozen in the presence of air was very poor.

Stretching the sugar ration for frozen foods, J. D. WINTER. (Minn. Expt. Sta. et al.). (*Quick Frozen Foods*, 4 (1942), No. 11, pp. 23, 29, fig. 1).—Experiments initiated in an attempt to find a way of eliminating fondantlike recrystallization of sugar that sometimes occurs in a product during freezing storage showed that the problem could be solved by replacing with corn sirup (the crystal white, enzyme-converted type) about one-fourth to one-third of the cane or beet sugar ordinarily used. The effect of the corn sirup was to cause the sugar to crystallize in very fine crystals which readily dissolved when the fruit was thawed. Even larger proportions of corn sirup—up to 50 percent of the sugar ordinarily used—could be used in frozen fruits without noticeably affecting the flavor or quality of the product. The corn sirup substitutions were made on the dry weight basis, it being considered that the enzyme-converted sirup as packed for the market contained about 25 percent moisture. It was also found that a light, mild-flavored honey could be used to replace some of the cane or beet sugar; the honey, being sweeter than corn sirup, could be used in replacement on a pound to pound basis without allowance for moisture content. Specific recommendations are given concerning the use of corn sirup (and in some cases honey) in preparing strawberries, raspberries, peaches, blueberries, and cantaloups for freezing and frozen storage.

Iron content of potatoes as influenced by cooking method, M. F. PFUND and H. W. NUTTING. (Cornell Univ.). (*Food Res.*, 7 (1942), No. 3, pp. 210-217).—New York State Smooth Rural potatoes, grown under known conditions, were used in this study, which is described in detail as to methods of preparation, cooking, sampling, and analysis. Iron was determined, with great care to prevent contamination, by the o-phenanthroline method by a procedure representing an adaptation of the method of Saywell and Cunningham. Certain samples were analyzed for ionizable iron by a modification of the procedure of Sherman et al. (E. S. R., 73, p. 416.) The flesh of raw potatoes, pared before testing, averaged 0.81 mg. of iron per 100 gm. The flesh of potatoes steamed after paring and of those boiled whole and peeled after cooking contained similar amounts (as calculated back to the raw basis). Significantly lower values (0.72-0.73 mg. per 100 gm.) were obtained, however, for pared potatoes that had been boiled whole, boiled in quarters, or soaked whole for 6 hr. previous to boiling. Potatoes cooked by these latter methods had apparently lost 10 percent of their iron during boiling. The iron content of baked potatoes removed from their thick skins amounted to 0.89 percent on the cooked basis; this high value was apparently due to loss of moisture during baking, since recalculation to the raw basis gave a value of 0.68 percent. High concentrations of iron were found in the thick crusty skins of baked potatoes (1-2 mg. in

the skin of a potato weighing about 200 gm.). The total iron and ionizable iron content of potatoes were found to be similar. The addition of salt to the water in which the pared potatoes were boiled had no significant effect on the quantity of iron lost.

Blackening of cooked potatoes—properties of the pigment, H. W. NUTTING. (Cornell Univ.). (*Food Res.*, 7 (1942), No. 3, pp. 227-235, figs. 3).—In further investigation of the stem blackening of cooked potatoes (E. S. R., 87, p. 448), some properties of the pigments from the blackened and nonblackened potatoes were determined and compared with those of melanin prepared from the raw potatoes by mechanical separation from water extracts or by the tyrosine-tyrosinase reaction. A gray and a yellow pigment were obtained from water extracts from the discolored portions of the cooked potatoes by chromatographic adsorption on aluminum oxide; a similar yellow pigment was obtained from unblackened tubers. While the dark pigment could be removed from the blackened potato with water, acid, or alkali, it could be desorbed from the aluminum oxide only by treatment with acid or alkali. Acid extracts of either material were colorless, but cautious addition of alkali restored the dark color while excess of alkali resulted in a persistent yellow color; alkaline extracts were yellow or brown-yellow, but could be darkened by cautious addition of acid. Apparently, therefore, these two pigments were related. Treatment of nonblackening tubers or of darkened portions of the blackening tubers with ethyl alcohol yielded a yellow extract from which no yellow pigment could be crystallized, however. In the adsorption tests the adsorbed yellow pigment showed the flavone type color reactions, gave an intense yellow solution in sodium hydroxide, lost color in dilute acids but turned bright yellow in concentrated HCl, and gave a dark gray-green color with ferric chloride solution. The dark pigment from the blackened tubers was unlike the melanin, which was insoluble in water or organic solvents, unaffected by cold acids, and soluble in dilute alkali, from which it could be reprecipitated with acid. Moreover, the ultraviolet absorption spectra of the melanin and the dark pigment were not alike; the spectra of the dark and the yellow pigments, however, were similar although not identical.

Soils and fertilizer affect food value as well as acre-yield of turnip greens, L. McWHITER and M. GIEGER (*Miss. Farm Res. [Mississippi Sta.]*, 5 (1942), No. 7, pp. 7, 8).—Analyses of Seven-top turnip greens from the same seed source in different seasons showed marked variations in the calcium and phosphorus contents of the greens grown at five places. The greens grown on soil high in calcium and phosphorus were relatively high in both minerals. Of the fertilizer elements applied—N, P, Ca, and K—nitrogen had the greatest effect. The percentage amount of calcium in turnip greens was somewhat lessened by nitrogen fertilization of the plats, but the effect on the phosphorus varied in different places. The nitrogen fertilization so increased the yield (from three to eight times that on nonnitrogen plats) that the total amount of both calcium and phosphorus from the full harvest of the greens was increased roughly in proportion to the increase in yield. Moreover, the addition of nitrogen greatly improved the quality of the greens, making them more succulent and tender than the greens receiving no nitrogen. Thus, greens that are good sources of calcium and phosphorus can be produced on fertile soils that are high in both calcium and phosphorus.

Pickles and the national diet, F. W. FABIAN. (Mich. State Col.). (*Canner*, 94 (1942), No. 9, pp. 20-22).—Data are presented on the proximate composition and vitamin and mineral content of fresh cucumbers and six commercial types of cucumber pickles. That pickles are poor sources of minerals and vitamins

is indicated by the following values reported: Ca. 0.0114-0.0636 percent; P, 0.0161-0.0901 percent; Fe, 3.0-20.6 mg. per kilogram; Cu, 2.5-8.5 mg. per kilogram; vitamin A, 292.0-600.0 International Units per 100 gm.; vitamin B, 0.0-8.0 I. U. per 100 gm.; vitamin B₂, 10.0-17.0 Sherman-Bourquin units per 100 gm.; vitamin C, 40.0-200 I. U. per 100 gm.; and vitamin D, lacking (0.0).

Sanitization of beverage glasses, W. G. WALTER. (N. Y. State Expt. Sta.). (*Jour. Bact.*, 43 (1942), No. 1, pp. 114-115).—A survey was conducted over a 2-mo. period to determine the nature of the bacterial flora occurring on beverage glasses in six taverns where three different sanitization procedures were employed. From the nature of the colonies developed on plates seeded from the glasses, it appeared that an alkyl-dimethylbenzylammonium chloride rinse solution generally resulted in a more marked decrease in the number of organisms and the elimination of coliform types from the rims of glasses than did a similar treatment with cold water or the chlorine compounds available. Glasses dried with toweling had fewer organisms on the rims than those which were wet from dipping in chlorine and water.

Effect of tea on energy metabolism of children, J. WHITACRE. (Tex. Expt. Sta.). (*Jour. Home Econ.*, 34 (1942), No. 3, pp. 187-192, fig. 1).—Children from 10 to 13 yr. old served as subjects in this study of their metabolic rate as determined under controlled conditions at intervals (1) after the ingestion of 300 cc. of chilled tea with added lemon juice and sugar, furnishing about 170 calories and 0.03 gm. of caffeine and (2) after the ingestion of the same volume of chilled lemonade containing the same amount of lemon juice and sugar as did the tea. No attempt was made to influence the diet of the children in these tests except that those in one group in which the factor of tolerance was considered were given tea of the standard test strength for a week or more preceding the tests. The observed maximum increases, over the basal rate, in oxygen consumption following the ingestion of these beverages indicated that they induced about the same amount of stimulation in children. In no case was the stimulating effect of tea consistently greater than that of lemonade, and no evidence appeared of the establishment of any tolerance. It is concluded that caffeine in the iced tea of moderate strength caused little, if any, rise in the metabolic rate of the children studied. It is suggested that too much stress may have been placed heretofore on the bad effect of tea as far as its influence on energy metabolism is concerned.

Physical fitness of children from different economic levels in Chicago, M. C. HARDY, H. H. BOYLE, and A. L. NEWCOMB (*Jour. Amer. Med. Assoc.*, 117 (1941), No. 25, pp. 2154-2161, figs. 2).—Observations are presented on the incidence of certain health problems among over 6,000 children from 2 to 18 yr. of age (88 percent between 5 and 14 yr.) and about equally divided between the sexes. The children, all of whom were examined by pediatricians between January 1939 and October 1940, represented widely different income levels and various types of community areas in Chicago.

The findings as summarized indicate that the need for professional health services, such as medical and dental care, immunization against diphtheria, and vaccination against smallpox, was no less among children from nonrelief than from relief families, but that there was an association between low income and poor physical conditions, such as poor general health, underweight, poor posture, etc., which may not have required professional services. A larger proportion of Negro than of white children was in need of medical care, and this was also true of the general incidence of underweight and other signs of unsatisfactory physical conditions. Adequacy of the diet was directly associated with economic status, and the relation was noted more frequently

among the Negro than among the white children. The intake of fruits and vegetables was inadequate at all income levels.

"Evidence of the need for health supervision and health education at all economic levels is strikingly shown by the results of this study. Poor nutrition is clearly manifest in a composite of flabby muscles, underweight, pale mucous membranes, round shoulders, fatigue posture, bowlegs, knock-knees, flat feet, carious teeth, and inadequate diets. At no income level is the general health picture satisfactory, but at the low levels it is definitely unsatisfactory."

Geophagy (dirt eating) among Mississippi Negro school children, D. DICKINS and R. N. FORB. (Miss. State Col.). (*Amer. Sociol. Rev.*, 7 (1942), No. 1, pp. 59-65).—In this survey on the prevalence of dirt or clay eating, conducted in 11 Negro schools in a single county in Mississippi, great care was taken to avoid opportunities for coaching the children in the answers to the questions of whether or not they had eaten dirt during the 10- to 16-day period immediately preceding the study. The questionnaire contained 22 items, most of which were foods and beverages common to the locality, but with clay and dirt included twice. In the 207 acceptable replies obtained, 52 of the children gave yes as an answer for dirt eating, while 135 gave no as an answer both times. Seven children left the item blank both times and 13 were not consistent in their replies. The replies from the individual schools varied considerably. It is thought that these differences may have reflected the quality and quantity of clay banks in the different districts, as clay soils were the only kind of dirt eaten. Apparently the habit was locally known as dirt eating rather than clay eating, as 55 children left both questions concerning clay blank and the replies of the others were inconsistent. There appeared to be some relation between the dirt eating habit and the deficiency of the diet in iron-containing foods, but it is emphasized in the report that information on the quantity of iron-rich foods eaten is necessary before definite conclusions on this point can be drawn. "If the hypothesis of dirt eating to make up a diet deficiency should fail to be supported by further investigation, then we may have to conclude, as do most of the Negroes themselves, that dirt eating is simply a culture trait like dipping snuff or smoking."

The utilization of the calcium of carrots by adults, H. BREITER, R. MILLS, E. RUTHERFORD, W. ARMSTRONG, and J. OUTHOUSE. (Univ. Ill.). (*Jour. Nutr.*, 23 (1942), No. 1, pp. 1-9).—The seven adults participating in this study had served as subjects in the previously reported study of their utilization of milk calcium (E. S. R., 86, p. 416), the same basal period, in which the daily calcium intake averaged 270 mg., having served for the two test periods. During the period in which the carrot calcium was being studied, each subject consumed 700 gm. of carrots daily. This quantity of the vegetable furnished 202 mg. of calcium; the total daily calcium intake during the 35-day test period averaged 449 mg. During this period all subjects were in negative calcium balance, the daily net losses by subjects being 34, 72, 58, 74, 58, 49, and 121 mg., respectively. During the basal period the means of the negative balances in the above order were 67, 88, 80, 67, 120, 64, and 141 mg. "On the basis of differences between the intakes of these two periods and differences in the magnitude of the negative balances, the amount of carrot calcium utilized was computed; the values obtained were 17.6, 8.9, 12.9, 0.0, 33.5, 9.2, and 11.4 percent, averaging 13.4. Five of these seven subjects showed poorer utilization of the carrot calcium than they did of milk calcium in a previous study."

The biochemical defect in choline-deficient rats, H. P. JACOBI and C. A. BAUMANN. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 65-

76).—Young rats kept for 7 days on a choline-free diet with or without a supplement of ethanalamine developed severe kidney hemorrhage, whereas this condition did not develop in rats receiving choline supplements. The choline content of rats with symptoms of "choline deficiency" was not reduced, but was slightly greater than that of the animals receiving choline. The hemorrhagic kidneys contained somewhat more choline than did the normal kidneys. No sex difference was observed in the choline content of young rats. It is concluded, therefore, that the hemorrhagic kidneys were due to the lack of a methyl-containing essential other than choline itself. In other tests young rats were given diets in which the cystine was replaced by arachin, which is low in methionine and, therefore, furnished relatively few labile methyl groups. The choline content of these rats remained essentially normal; their weight decreased, however, and they developed kidney hemorrhages. The addition of choline to the arachin diet prevented the kidney lesions, but did not prevent loss in weight. Since choline was effective in the absence of adequate dietary methionine, it was evident that methionine was not the methyl compound whose absence caused kidney lesions. Rats on a synthetic diet free of choline grew to maturity and reproduced.

Domestic water and dental caries.—III, Fluorine in human saliva, F. J. McCLURE (*Amer. Jour. Diseases Children*, 62 (1941), No. 3, pp. 512–515).—Parafin-stimulated saliva from normal adults living in areas where the drinking water contained no fluorine was found to average about 0.10 p. p. m. of fluorine. Specimens of saliva obtained from school children in Amarillo, Tex., where there were from 3.8 to 4.0 p. p. m. of fluorine in the drinking water, averaged slightly above 0.10 p. p. m., and pooled specimens of saliva collected from subjects of epidemiological studies of dental caries (E. S. R., 82, p. 713) in various cities in which the fluorine in the drinking water varied from 0.0 to 1.8 p. p. m. also contained about 0.10 p. p. m. The fluorine content of these latter samples showed no consistent effect of the levels of fluorine in the drinking water. "No conclusions appear to be justified at this time with regard to the significance of the quantity of fluorine which is normally present in saliva. Any function which this normal quantity or any slight excess above normal may have as a partial preventive of dental caries remains to be demonstrated. More data are needed also to establish any relation between the fluorine content of the drinking water and the resulting excretion of fluorine in the saliva."

A study of the relationship of oral *Lactobacillus acidophilus* and saliva chemistry to dental caries, F. A. ARNOLD, JR., and F. J. McCLURE (*Pub. Health Rpts. [U. S.]*, 56 (1941), No. 30, pp. 1495–1514, figs. 3).—From observations on 127 white school children living in Arlington, Va., it was found that a close correlation existed between dental caries activity, measured by repeated clinical examination, and the number of *L. acidophilus* organisms in the saliva. Data on total solids, organic matter, ash, total nitrogen and nitrogen fractions, pH of isoelectric zone, and oxygen consumption of stimulated saliva obtained at 2- and 3-mo. intervals were found to bear no relation to the numbers of *L. acidophilus* in the saliva or to the degree of caries activity as determined by clinical examination.

The oral manifestations of vitamin deficiencies, L. A. ROSENBLUM and N. JOLLIFFE (*Jour. Amer. Med. Assoc.*, 117 (1941), No. 26, pp. 2245–2248).—This address includes, in addition to a description with references to the literature of oral lesions attributable to deficiencies of ascorbic acid, nicotinic acid, and riboflavin, a case history demonstrating the progressive production of characteristic glossitis in a patient maintained on a diet low in the vitamin B complex supplemented by nicotinic acid, thiamin, ascorbic acid, and vitamin A, and the

rapid improvement of the tongue condition following the administration of pyridoxin (vitamin B₆). This condition has been noted among a number of patients treated with nicotinic acid and riboflavin.

Vitamin content of green snap beans. Influence of freezing, canning, and dehydration on the content of thiamin, riboflavin, and ascorbic acid. K. T. FARRELL and C. R. FELLERS. (Mass. Expt. Sta.). (*Food Res.*, 7 (1942), No. 3, pp. 171-177).—Green snap beans of the Bountiful variety grown on plats at the Massachusetts Experiment Station were picked throughout the tests at the same degree of maturity. They were assayed for thiamin by the vitamin B₁ rat-assay method of Booher and Hartzler (E. S. R., 83, p. 131), for riboflavin by the rat-growth method of Bourquin and Sherman (E. S. R., 66, p. 410), and for ascorbic acid by the procedure of Mack and Tressler (E. S. R., 78, p. 154). Quick freezing when preceded by 2 min. of blanching in boiling water conserved the thiamin, riboflavin, and ascorbic acid in the snap beans to the highest degree of all the processing methods. The importance of the blanching process in the conservation of the vitamins was indicated by the decidedly lower values obtained for the products frozen without preliminary blanching. The frozen beans lost a total of 22 percent of their thiamin content, no appreciable amount of their riboflavin, and about 47 percent of their ascorbic acid upon storage for 12 mo. at -4° F. Canning (in glass or tin and with preliminary blanching) caused moderate losses of thiamin (10-18 percent), little or no loss of riboflavin, and about a 75-percent loss of ascorbic acid; after storage for 12 mo. the loss of thiamin increased to about 45 percent, but there was little further loss of either riboflavin or ascorbic acid. About 30 percent of the thiamin and riboflavin and 50 percent of the ascorbic acid of the canned product were present in the liquid portion. The beans lost but little of their thiamin and riboflavin upon dehydration and subsequent long storage. Ascorbic acid, however, was almost totally destroyed by dehydration. The dehydrated beans, soaked 24 hr. and cooked, showed losses of thiamin and riboflavin amounting to 45 and 33 percent, respectively. There were very small or no losses of these vitamins in cooking the fresh frozen or canned beans, but ascorbic acid losses amounted to 24, 12, and 6 percent, respectively.

A compilation of the vitamin values of foods in relation to processing and other variants. L. E. BOOHER, E. R. HARTZLER, and E. M. HEWSTON (*U. S. Dept. Agr. Cir.* 638 (1942), pp. 244).—The vitamin A value, thiamin, ascorbic acid, riboflavin, and vitamin D contents of 290 foods, as recorded in the literature from the date of the establishment of the latest international standard for each vitamin through December 1940, are presented in this circular. The criteria for the inclusion of vitamin values were that the values should be expressed in International Units or absolute weight values, and that whether determined by biological or chemical means positive controls were included in the experiments. The data are arranged to show the effect of variety or species, geographical location, soil conditions or feeding practices, processing, and method of analysis on vitamin content.

Interaction of vitamins A and E. A. W. DAVIES and T. MOORE (*Nature [London]*, 147 (1941), No. 3739, pp. 794-796, fig. 1).—Further evidence (E. S. R., 85, p. 573) is given of the interaction of vitamins A and E in that (1) in rats restricted to a diet deficient in both of these vitamins the reserves of vitamin A accumulated through preliminary feeding of large amounts of this vitamin are exhausted more rapidly than in controls with the same initial stores but given *dl*- α -tocopherol during the depletion period, and (2) in rats during prolonged deficiency of vitamin E secondary deficiency of vitamin A develops, as shown by the disappearance of vitamin A from the liver. The teeth of these animals

also showed whiteness, generally held to be an effect of vitamin A deficiency, but which the authors are inclined to consider as a common result of deficiency of either vitamin A or vitamin E.

Non-crystallizable vitamin A, J. G. BAXTER, P. L. HARRIS, K. C. D. HICKMAN, and C. D. ROBESON (*Jour. Biol. Chem.*, 141 (1941), No. 3, pp. 991-992).—Free vitamin A in the concentrate resulting from saponification of the distillate from liver oil of the ling cod was found to be in two forms—that which could be crystallized from ethyl formate and that which resisted crystallization. This latter form, constituting 46 percent of the initial vitamin A, had an absorption spectrum similar to that of the crystalline preparation. Conversion factors (relative biological potencies) of the crystalline and noncrystalline preparations were determined as 2,600 and 1,500, respectively. These factors differ from the generally accepted value of 2,000 for the whole oil. It is suggested that the existence of more than one variety of vitamin A, spectrally identical but different in crystallizability and potency, if substantiated, would help to explain why natural oils have been found to have different conversion factors; these differences could be due to the presence of significantly different proportions of these two vitamin A's or inactive material absorbing sharply at 328 mμ.

The comparative physiologic value of injected carotene and vitamin A, J. G. and E. J. LEASE, H. STEENBOCK, and C. A. BAUMANN. (Wis. Expt. Sta.). (*Jour. Lab. and Clin. Med.*, 27 (1942), No. 4, pp. 502-510).—In vitamin A-deficient rats carotene injected intraperitoneally or subcutaneously in an aqueous colloidal suspension or in oil solution restored growth and cured ophthalmia. Although from 10 to 100 times as much was required as when administered orally, the effect was less prolonged, and there was little storage as vitamin A in the liver. Particles of unchanged carotene were found at the sites of the injection and in the liver, omentum, and in the lymph nodes of the peritoneal cavity. Much of the injected carotene could not be traced. In contrast with these findings, vitamin A was utilized about as effectively when injected as when given orally. Aqueous colloidal preparations were utilized to a somewhat greater extent when injected and oil solutions when given orally. In contrast with carotene, most of the injected vitamin A accumulated in the liver rather than at the site of injection.

The effect of dibenzanthracene, of alcohol, and of other agents on vitamin A in the rat, C. A. BAUMANN, E. G. FOSTER, and P. R. MOORE. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 142 (1942), No. 2, pp. 597-608).—The possibility that dibenzanthracene, previously shown to increase the rate of depletion of liver stores of vitamin A in the rat (E. S. R., 86, p. 422), might alter the distribution of vitamin A between the liver and other organs was tested by comparing the effects of this substance with other treatments likely to affect vitamin A storage, and by attempting to determine the fate of the fraction of vitamin A thus withdrawn from the liver.

In rats given enough vitamin A to promote good liver stores, the intraperitoneal injection of dibenzanthracene was followed by a shift to the kidneys of as much as 50 percent of the total body vitamin A as compared with not more than 5 percent in comparable uninjected animals. However, the increase in the vitamin A of the kidneys accounted for only about 10 per cent of the amount withdrawn from the liver. The effect of the dibenzanthracene was not counteracted by cystine or by high or low levels of vitamin E. Diets low in protein decreased the storage of vitamin A in the liver and increased the rate of its depletion. The ingestion of a 15-percent solution of alcohol increased the rate of depletion of vitamin A from the liver but to a less extent than dibenzanthra-

cene and did not increase the content of the vitamin A in the kidneys. The results are considered to be in harmony with the suggestion that vitamin A is held in the liver in the form of a protein complex.

Nicotinic acid in blood and in urine, B. D. KOCHHEAR (*Indian Jour. Med. Res.*, 29 (1941), No. 2, pp. 341-350).—In continuation of previous work (E. S. R., 86, p. 868), this study was undertaken to observe the changes in the blood levels of nicotinic acid following a test dose and to determine whether or not continuous intake produces a condition of saturation in the blood. Urinary excretion of nicotinic acid was also observed at 3-hr. intervals in two individuals on a normal diet as well as fasting.

Oral administration of the nicotinic acid in 200- or 300-mg. doses produced a sudden temporary rise in the blood content of nicotinic acid, reaching a peak in 30 min. Continuous intake of nicotinic acid resulted in a slight gradual increase in the blood content, reaching a maximum which was not affected by prolonged intake. Corresponding to the rise in nicotinic acid in the blood, there was a sharp increase in urinary excretion, reaching a maximum within the first hour. Fasting subjects showed lowered excretion of nicotinic acid but an enhanced response to a test dose.

Studies on the metabolism of pantothenic acid in man and rabbits, P. B. PEARSON. (Tex. Expt. Sta.). (*Amer. Jour. Physiol.*, 135 (1941), No. 1, pp. 69-76).—In continuation of earlier work (E. S. R., 87, p. 600), the author has studied by the same methods the effect of massive doses of calcium pantothenate on its content in the blood and the rate of excretion in the urine of rabbits and humans.

In both species there was a rapid increase in the content of calcium pantothenate in the blood following the administration of a large dose, the extent of the increase appearing to depend on the size of the dose per unit of body weight and the mode of administration. The increase was higher on parenteral than on oral administration. There was also a definite relationship between the amount of pantothenic acid recovered in the urine and the maximum level in the blood. In three healthy male subjects, the urine collected at stated intervals for 26 hr. after the ingestion of 1 gm. of calcium pantothenate in aqueous solution at 6 a. m. just after the bladder had been emptied showed the highest content of the pantothenate in the sample collected at the end of the first 2 hr. This was followed by gradual decreases in the content of pantothenic acid in both blood and urine. The total recovery in 26 hr. amounted to only 7.8, 11.7, and 6.8 percent of the quantity ingested. In a rabbit given 400 mg. of calcium pantothenate orally, 52 percent was recovered in the urine within 24 hr. as compared with 74 percent when the same amount was given parenterally. The question as to what happens to the pantothenic acid not removed in the urine has not been answered. There was no evidence of toxicity following the administration of the large doses of pantothenic acid nor were there any unfavorable effects such as flushing of the skin.

Pantothenic acid in the nutrition of the rat, L. M. HENDEBSON, J. M. MCINTIRE, H. A. WAISMAN, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Nutr.*, 23 (1942), No. 1, pp. 47-58).—Following a review of the conflicting literature on pantothenic acid as the anti-graying factor, a series of studies is reported in which definite graying was produced in from 4 to 6 weeks in black and piebald rats on a synthetic ration deficient in pantothenic acid but containing presumably adequate amounts of thiamin, pyridoxin, riboflavin, nicotinic acid, and choline. The graying was prevented or cured by levels of pure calcium pantothenate above 40 μ g. per day. The rate of growth paralleled the pantothenic acid intake up to 80 μ g. per day. Although there was

no graying at higher levels, growth was improved by additions of 200 and 500 μg . In balance experiments very little pantothenic acid was excreted on amounts up to and including 80 μg . On the next higher level, 150 μg ., there was a marked increase, suggesting that the requirement of pantothenic acid lies somewhere between these two levels or at approximately 100 μg . Rats fed a heated grain ration supplemented with the B vitamins other than pantothenic acid showed graying, which was also prevented and cured with synthetic calcium pantothenate. A rusty graying occurred with copper deficiency and was cured by the addition of copper. Hydroquinone was ineffective in producing graying in rats on synthetic or milk rations, and *p*-aminobenzoic acid was entirely ineffective against the graying produced in rats by the synthetic ration used by the authors.

The succinoxidase system in riboflavin-deficient rats, A. E. AXELROD, V. R. POTTER, and C. A. ELVEHJEM. (Wis. Expt. Sta.). (*Jour. Biol. Chem.*, 142 (1942), No. 1, pp. 85-87).—Determinations of succinoxidase activity of various tissues of rats on a riboflavin-deficient diet and of similarly depleted rats subsequently given riboflavin therapy showed that the dietary intake of riboflavin had a definite effect upon the succinoxidase content of liver tissue only. The results are taken as indirect evidence that one or more components of the succinoxidase system are flavoproteins.

Excretion of thiamin and its degradation products in man, H. POLLACK, M. ELLENBERG, and H. DOLGER (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 414-417, figs. 3).—Using the method of Schultz, Atkin, and Frey (*E. S. R.*, 85, p. 727) for determining both thiamin and the pyrimidines in the urine, the authors studied the excretion of these substances in human subjects.

During a 10-day thiamin deprivation period in three subjects, two normal and one with ileojejunitis, the absolute amounts of pyrimidines excreted remained at approximately the same level but the free thiamin disappeared almost completely, the thiamin-pyrimidine ratio changing during the period from approximately 9:1 to 1:9. The test dose method of Dolger et al. (*E. S. R.*, 85, p. 702), applied at the beginning and end of a 10-day deprivation period, showed no differences in response even although free thiamin was absent from the urine at the time of the second test. This finding, together with the complete absence of any subjective and objective signs of vitamin B₁ deficiency, is thought to indicate that the determination of free thiamin alone in the urine is an index only of the dietary intake immediately preceding the measurement, but that the combined thiamin pyrimidine determination is capable of distinguishing between the low values of thiamin resulting from long or only temporary deprivation.

When a group of normal individuals was given the thiamin load test, over 60 percent of the yeast fermentation stimulating substance in the urine was free thiamin, while in a group of unselected hospitalized patients similarly tested 25 percent excreted more pyrimidine than thiamin. Tests on a single B complex-deficient subject during the period of daily intravenous injection of 100 mg. of thiamin hydrochloride showed an absolute increase in the excretion of both thiamin and pyrimidine but a decrease in the relative utilization of the thiamin, suggesting that frequent divided dosage of thiamin is preferable to a single massive dose.

Ascorbic acid content of four varieties of raw wines, M. KRAMER and G. H. SATTERFIELD. (Univ. N. C. et al.). (*Food Res.*, 7 (1942), No. 2, pp. 127-129).—Apple, peach, and black and white scuppernong wines were obtained from a North Carolina winery just prior to the finishing process, the wines at this time having been stored for a year or less. They were analyzed for ascorbic

acid by a method (described) which was essentially that of Tauber and Kleiner (E. S. R., 75, p. 588). No ascorbic acid was found in the wines.

Ascorbic acid content of seven varieties of muscadine grapes, T. A. BELL, M. YARBROUGH, R. E. CLEGG, and G. H. SATTERFIELD. (Univ. N. C. et al.). (*Food Res.*, 7 (1942), No. 2, pp. 144-147).—The varieties of grapes were grown in North Carolina in 1937, 1938, and 1939 seasons on the same type of soil and received the same fertilizer treatment. The fruits analyzed were firm and ripe (or green as desired) and of characteristic size for each variety. The ascorbic acid content, as determined by the method of Mack and Tressler (E. S. R., 78, p. 154), averaged 6.8 mg. per 100 gm. of the edible portion of ripe scuppernong grapes and from 4.1 to 5.5 mg. per 100 gm. of the Labama, Eden, Thomas, and James varieties. The Mish and Hopkins varieties contained negligible quantities, averaging 1.8 and less than 0.2 mg. per 100 gm., respectively. The green scuppernongs averaged 6.7 mg. of ascorbic acid per 100 gm. of edible portion. The skins of both the green and the ripe scuppernong grapes, containing, respectively, 20.2 and 18.4 mg. per 100 gm., had about three times the ascorbic acid content of the edible portion.

Losses of vitamin C during cooking of parsnips, E. J. BROWN and F. FENTON. (Cornell Univ.). (*Food Res.*, 7 (1942), No. 3, pp. 218-226).—Parsnips of the Hollow Crown variety grown in the Cornell University garden on fertilized sandy loam were dug in November, at which time they were placed under constant storage conditions (34°-35° F. and 95-100 percent humidity) until used in the tests, which continued at intervals into early March. The ascorbic acid content of the raw and cooked parsnips and the cooking water was determined by the dye titration method according to the procedure of Mack and Tressler (E. S. R., 78, p. 154). The raw parsnips analyzed in November, December, and January contained from 15 to 30 mg. of ascorbic acid per 100 gm.; during February and March only from 7 to 18 mg. per 100 gm. The relative distribution of the ascorbic acid in the different parts of the parsnip varied during the storage period. The parsnips, whole and unpeeled, peeled and cut in pieces (radially), and peeled and sliced crosswise were cooked by boiling, by steaming, and in two makes of pressure saucepans. Of these methods, boiling whole (unpeeled) and cutting in pieces and cooking in the pressure saucepan gave the best ascorbic acid retentions, 91 and 90 percent, respectively. "Parsnips steamed whole, unpeeled, and parsnips cut in pieces and boiled retained 86 percent of their original vitamin C. In both boiling and steaming the parsnips cooked whole, unpeeled, retained more vitamin C than did those which had been sliced or cut in pieces. Parsnips boiled in enamel and Pyrex pans retained more vitamin C than those boiled in stainless steel and aluminum pans, 84 and 81 percent, against 66 and 71 percent, respectively. Parsnips cut in pieces cooked 5 min. (overdone) in the pressure saucepan showed a retention of only 78 percent of the original vitamin C, whereas the retention was 90 percent at the done state after 2 minutes' cooking."

The influence of intermittent consumption of vitamin C on the development of scurvy, S. S. ZILVA (*Biochem. Jour.*, 35 (1941), No. 10-11, pp. 1240-1245, figs. 2).—The effect of intermittent rather than daily doses of ascorbic acid was tested on guinea pigs, both saturated and unsaturated with vitamin C at the beginning of the experiment. Daily doses of 2 and 5 mg. of ascorbic acid were adopted as standards, representing, respectively, the quantities necessary for preventing microscopic changes in the structure of the teeth and for bringing about deposition of traces of the vitamin in selective organs. A comparison was made of the effects of these doses when administered for 90 days to growing guinea pigs on a scorbutic diet daily, or in proportional amounts every

other day, every third day, and weekly. No significant differences were observed in the response of the different animals in growth and in protection against scurvy except in the case of those receiving 14 mg. of ascorbic acid once a week. The animals in this group showed definitely poor growth and slight symptoms of scurvy on post-mortem examination. There were no significant differences between animals saturated and unsaturated at the beginning of the experiment. When 85 mg. of ascorbic acid was given once a week, all of the animals grew well and were protected against scurvy.

Attempting to interpret these results in terms of human beings, using for reference earlier work of the author and reports of Crandon et al. (El. S. R., 86, p. 871), Fox (El. S. R., 86, p. 872), and others dealing with human subjects, the author suggests that 120 mg. of ascorbic acid every 30 days would be sufficient to protect man from macroscopic scurvy. In his opinion, as far as the civilian population of England is concerned, a general vitamin C deficiency at any time of the year need not be greatly feared.

Death of embryos in guinea pigs on diets low in vitamin E, A. M. PAPPENHEIMER and M. GOETSCH (*Soc. Expt. Biol. and Med. Proc.*, 47 (1941), No. 2, pp. 268-270).—In this preliminary report observations are recorded indicating that the guinea pig, like the rat and mouse, requires an abundant supply of vitamin E and that an inadequate intake results in the death of the embryo in the uterus. Previous failure to demonstrate this is attributed to the fact that guinea pigs on a vitamin E-low diet usually die of muscular dystrophy before sexual maturity. In the experiments reported enough vitamin E (from 5 to 10 mg. weekly) was given to prevent the development of muscular dystrophy, but this amount was insufficient to prevent resorption of the embryo in a large proportion of the cases. The authors had the assistance of C. Schogoleff.

Hemoglobin production increases with severity of anemia, F. S. ROBSCHUIT-ROBBINS and G. H. WHIPPLE (*Amer. Jour. Physiol.*, 134 (1941), No. 2, pp. 263-267).—Dogs whose normal hemoglobin level was 20 or 21 gm. percent were brought to a severe or a moderate anemia level, 6 or 11 gm. hemoglobin percent, respectively, by the standard procedure used in the authors' laboratory. Hemoglobin production for a 2-week period was then observed in animals receiving diet supplements of liver, iron, or liver extract containing iron. The responses were similar for the different dietary factors and indicated that the production of new hemoglobin increased as the hemoglobin deficit (anemia) became more pronounced. The severe anemia level gave maximum stimulus for the production of hemoglobin, and the moderate anemic level gave hemoglobin production of approximately two-thirds of this maximum. The hemoglobin production, therefore, seemed to run parallel to the degree of anemia.

Hemorrhagic disease of the newborn, L. SNEDEKER (*Jour. Ped.*, 19 (1941), No. 1, pp. 1-15).—Data from case records of two hospitals over a considerable number of years are reported on 358 cases of hemorrhagic disease. Data on prothrombin levels were not available for any of these cases, but evidence in the literature is interpreted as indicating that prothrombin deficiency may be a cause of at least one form of hemorrhagic disease but not a consistent finding in all cases. The evidence available at present is considered insufficient to justify the conclusion that cases of hemorrhagic disease can be treated satisfactorily by the administration of vitamin K. "More data are needed on the prothrombin levels in normal and bleeding infants and on the effect of maternal diet, transfusion, and vitamin K on these levels. The relation between asphyxia and hemorrhagic disease of the newborn infant warrants investigation."

TEXTILES AND CLOTHING

Work clothes for women, C. L. SCOTT (*U. S. Dept. Agr., Farmers' Bul. 1905 (1942), pp. 16, figs. 14*).—The work clothes described and illustrated in this publication are designed for women doing active work in jobs of the factory, farm, and home. With the requirements of particular jobs in mind, the styles are planned with special features for safety, comfort, freedom of activity, and pleasing appearance. "These designs are released to patternmakers and the clothing trade as soon as they are completed. Most of the styles shown here are now on sale to the public through retail outlets either as commercial patterns or as ready-to-wear garments."

Clothing supplies for college girls and boys, A. BOWIE (*Miss. Farm Res. [Mississippi Sta.], 5 (1942), No. 7, pp. 1, 8*).—Sample inventories of clothing supplies of boys and girls attending two colleges in Mississippi showed the lowest total value for clothing on hand to be \$81 for any one girl and \$120 for any one boy; the maximum values, respectively, were \$529 and \$243. The amounts of money spent by the girls in 1 yr., as shown by their records, varied from \$12 to \$268; for the boys from \$40 to \$100. An average or typical list showing quantities and costs of clothing supplies is based on these and other college students' inventories and is presented, together with a minimum inventory list.

HOME MANAGEMENT AND EQUIPMENT

Family expenditures for education, reading, recreation, and tobacco: Five regions. Urban, village, and farm, D. MONROE, D. S. BRADY, M. Y. PENNELL, and M. H. COFFIN. (*U. S. Dept. Agr., Misc. Pub. 456 (1941), pp. [2] + V + 208, figs. 2*).—This report is one of the series from the consumer purchases study presenting facts concerning the incomes and consumption patterns of families in small cities and villages and on farms (*E. S. R.*, 87, p. 159). It is pointed out that education, reading, recreation, and tobacco occupy a position of secondary importance in the spending patterns of the groups of families at the various income levels in the five regions considered. In the Middle Atlantic and North Central regions, for example, formal education accounted for less than 2 percent of the total at all but one income level; reading for about 1 percent at all levels; tobacco for 1 or 2 percent; and recreation for from 1 to 4 percent at all but one level. These comparatively low direct outlays by families were made possible because of the schools, libraries, parks, and playgrounds maintained at public expense.

Housing in southern California, G. GRAY. (*Univ. Calif.*). (*Jour. Home Econ.*, 34 (1942), No. 5, pp. 300-301).—This paper presents a brief picture of the types of housing, particularly the contrasting extremes, and of homeownership in and around Los Angeles. Some of the hazards of ownership and some of the Federal housing troubles are pointed out. It is noted that in Los Angeles, as in many other areas, slum clearance is being conducted, while at the same time the basis for future slums is being laid through the operation of defense housing projects.

An analysis of pressure gasoline and pressure kerosene stoves, A. E. BARAGAR (*Nebraska Sta. Res. Bul. 127 (1942), pp. 63, figs. 39*).—One pressure kerosene and three pressure gasoline stoves built by nationally advertised manufacturers and obtained from open stock were used in the analysis of this type of appliance with regard to safety, efficiency, and general performance. Each stove differed from the others in type of cooking, type of oven, and

method of operation. All are described and illustrated by photographs of the stoves, the top burners, and the generator systems. The data obtained in the various tests are presented and discussed in sections on fuel supply (including tests with natural gas as well as gasoline and kerosene), products of combustion, cooking tops, and ovens. Among the practical points brought out in the final summary are the following:

"Even though on several occasions some stoves failed to function properly, it appeared that the greatest danger inherent with safe operation still remained the human factor of careless handling of gasoline around an open flame. . . . In some cases the percentage of carbon monoxide liberated by a burner was high, but in the extreme cases the concentration of CO in the room atmosphere would be such that a person could work for at least $1\frac{1}{2}$ hr. in a room having a volume of 1,000 cu. ft. where the air was changed once in 5 hr. and experience no perceptible effect from CO. . . . Less CO was found when a gasoline especially designed for stoves was used than when ordinary white unleaded motor fuel was used. (Thus from the point of view of completeness of combustion, it is probably better to pay the premium price for stove gasoline. . . . The flames at the burners on these gasoline and kerosene stoves cannot be turned low enough to prevent excessive evaporation without either the generator burner flame or the top burner flame extinguishing. When the burners were operating with the low inputs necessary just to maintain boiling, considerable odor was noticed and sometimes the products of combustion smarted the eyes. . . . While considerable temperature variations were found for the internal heat distributions in the ovens, actual baking tests, using bread, layer cakes, and baking powder biscuits, showed satisfactory oven performance." For differentiation of types and relative merits of each the original publication should be studied.

The steam pressure cooker, W. V. HALVERSEN. (Idaho Expt. Sta.). (*North-west. Sci.*, 16 (1942), No. 1, pp. 13-18, fig. 1).—The factors responsible for errors in the pressure gages of steam pressure cookers and the advantages of having the cooker equipped with a thermometer in addition to or in place of a pressure gage are discussed, and tables are given showing the errors in the pressure gages found in the examination of 38 pressure cookers used at different elevations from 1,000 to 6,000 ft., the proper gage pressures corresponding to specific processing temperatures at various altitudes, and the temperatures corresponding to the gage reading in pounds of steam pressure at sea level. A simple pressure gage tester is described and illustrated by diagram. "The seriousness of the condition of steam pressure cookers tested now in use can be judged by the following data: Of 146 pressure cookers tested, 30 pressure gages were accurate; on 63 gages the dials were so loose that they would shake back and forth over a range of 1 lb. or more without change in pressure; 31 fluctuated 2 lb. or more and 6 fluctuated 3 lb. or more; 87 were inaccurate to the extent that the dial also showed 1 lb. or more pressure than they should; 42 showed an inaccuracy of 2 or more pounds; 23 showed an inaccuracy of 3 or more pounds; 13 showed an inaccuracy of 4 or more pounds; 3 showed an inaccuracy of 5 or more pounds."

MISCELLANEOUS

Tables of orthogonal polynomial values extended to $n=104$, R. L. ANDERSON and E. E. HOUSEMAN (*Iowa Sta. Res. Bul.* 297 (1942), pp. 593-672, fig. 1).—A complete set of ξ values for $n=$ of Fisher and Yates (*E. S. R.*, 80, p. 572) to and including 104 is presented, with a brief simple description of the ξ method based on coded sugar prices from 1875 to 1936.

Farm Research, [July 1, 1942] (*Farm Res. [New York State Sta.]*, 8 (1942), No. 3, pp. 16, figs. 16).—In addition to articles noted elsewhere in this issue, this number contains Doctor A. J. Heinicke Named Station Director (p. 1); Growth and Development of Locker Plants, by C. W. DuBois (pp. 5, 6); and Hudson Valley Laboratory in New Location, by R. W. Dean (p. 16).

Abstracts of Bulletins No. 596-609, Circulars No. 91-94, and other publications during 1941, A. D. JACKSON (*Texas Sta. Cir. 96 (1942)*, pp. 49).—In addition to abstracts of the station's own publications as indicated, this circular contains abstracts of articles contributed by members of the staff for publication elsewhere. Some of these have been previously abstracted or are noted elsewhere in this issue, but there are also abstracts of the following: Symposium on Research With Tomatoes in the South—Recent Progress in Breeding and Improvement, by S. H. Yarnell (pp. 19-20); Comparative Cooking Time and Tenderness of Meal Cooked in Water and in an Oven of the Same Temperature, by S. Cover (p. 24); and The Pantothenic Acid Content of Royal Jelly, by P. B. Pearson and C. J. Burgin (p. 26). A classified subject list of available station publications is appended.

List of Farmers' Bulletins that have been superseded and the Farmers' Bulletins or other publications superseding them (*U. S. Dept. Agr., 1942*, pp. [1]+12).

³ The experimental work reported is for the most part referred to elsewhere in this issue.

NOTES

Arkansas University and Station.—The resignations are noted of E. L. Barger, head of the department of agricultural engineering; Walter Massey, scientific assistant in the Cotton Branch Station; and Lorin E. Harris and Milton W. Sanderson, instructors in animal industry and entomology. Thomas C. Guthrie, scientific assistant at the Rice Branch Station, and Hilliard Jackson, research assistant in rural economics, have entered military service. Recent appointments include Dr. T. C. Liu as research assistant in plant pathology, J. R. Tatum as assistant professor of sociology and assistant sociologist, Lorraine Adelaide Williams as assistant professor of home economics, Dr. Edgar Martin as instructor in animal industry and assistant animal husbandman, F. D. Miner as instructor in entomology and assistant entomologist, Geneva Johnson as instructor in home economics, T. R. Moberg as assistant forest economist, and Clay R. Moore as scientific assistant in the Cotton Branch Station.

California University and Station.—The H. E. Metcalf orchid collection, containing 2,700 plants of 1,400 different varieties and species mostly from Central and South America, has been donated to the botany division of the College of Agriculture for use in research on plant physiology.

The dairy industry division of the College of Agriculture at Davis is offering a 2-weeks course to train men and women as milk testers. These testers are much in demand since milk plants have lost many employees to the armed services and war industries.

Dr. Murray R. Benedict, professor of agricultural economics and agricultural economist, has been appointed Federal rent administrator in the San Francisco Bay region.

Connecticut [New Haven] Station.—Dr. Albert E. Dimond, plant pathologist, has been appointed assistant professor of botany in the University of Nebraska.

Kansas College and Station.—The Kansas State College Research Foundation has been organized, with President F. D. Farrell as chairman of the board of nine directors. Its charter is said to follow closely those of like organizations at a number of land-grant institutions.

Dr. William H. Metzger, assistant professor of soils from 1932 to 1935 and subsequently associate professor, died July 7 at the age of 43 years. A native of Indiana, he received the B. S. degree from Purdue University in 1922, the M. S. degree from the Kansas College in 1927, and the Ph. D. degree from the Ohio State University in 1931. He had also held positions as assistant in soils in the Pennsylvania College from 1922 to 1923, as county agent in Kansas from 1923 to 1927, and as assistant agronomist in the Arkansas Station from 1927 to 1929.

Leave of absence to enter military service has been granted R. J. Doll, assistant professor of agricultural economics; R. B. Cathcart, assistant professor of animal husbandry, and Leo Petri, technician in zoology. John C. Crupper, Jr., forest nurseryman at the Fort Hays Substation, has been succeeded by Jewell Harrison. H. J. Haas, junior agronomist in charge of dry land agriculture investigations at the Garden City Substation, has been transferred to the Northern Great Plains Field Station at Mandan, N. Dak., and has been succeeded by Hugh G. Myers. Other appointments include Emery C. Swanson as assistant in milling industry and A. Weybrew and Charles Wagoner as assistant chemists.

INDEX OF SUBJECTS

NOTE.—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R.U." to those of the experiment stations in Hawaii and Puerto Rico (University station); and "U.S.D.A." to those of this Department.

- Abacá* dry sheath-rot, cause and control, 233.
Abies grandis johnsoni, description, 677.
 Abortion—*see also* Bang's disease and *Brucella abortus*.
 equine virus, Ky. 857.
 in ewes, Wyo. 851.
 virus, of mares, Ky. 851.
 Absorptive form lining, use and purchase specifications, 128.
Acacia melanoxylon, culture of isolated roots of, 853.
 Acariasis of fowl, dog, and man, 851.
Acaulopage n.spp., destructive to soil amoebae, 530.
 Acetaldehyde, role in red wines, 181.
 Acetone, heat of combustion, 166.
 Acetonemia in cattle, physiologic and metabolic aspects, 568.
Achlya—
 flagellata, new *Rozella* parasitizing, 808.
 sexual hormones in, 488.
Achromotrichia in rats—
 development, nutritive factors involved, Pa. 589.
 effect of pantothenic acid alone and in natural products, 150.
 Acids—
 amino, *see* Amino acid(s).
 fatty, *see* Fatty acids.
 organic, preservative values, Mass. 761.
Aconitum spp., somatic chromosomes of, 360.
Actinobacillus lignieresii from sheep in Montana, 715.
Actinomyces—
 inhibitory action on fungi in culture, 486.
 staining, in aerial parts of potato, 236.
Actinomycetes—
 bacteriolytic properties, 33.
 classifying, value of pigmentation in, 34.
 distribution of antagonistic properties, 34.
 in soil processes, importance, N.J. 342.
 variation in, 33.
Actinomycin A, effect on bacteriophage and bacterial toxins and toxinlike substances, 710.
Actinomycin, effect on soil fungi and bacteria, 161.
Adelphocoris superbus studies, N.Mex. 303.
 Adolescents in high-income families, hemoglobin and erythrocyte values, 742.
 Adrenaline extracts, effect on blood sugar in chicks, 790.
 Adsorption analysis, chromatographic, 627.
Aecidium liriocarpum, telial stage of, description, 530.
Aedes spp., vectors of equine encephalomyelitis, 117.
Aeoloplus turnbulli bruneri, epizootic among, 247.
Aeolothrips melaleucus, notes, 307.
Aeolus mellillus life history, Ky. 831.
Aerobacter—
 aerogenes, lethal effect of drier rolls on, 348.
 aerogenes, pathogenicity for turkeys and response to agglutination test for pullorum disease, 723.
 and *Escherichia*, tests for differentiation, [N.Y.]Cornell 33.
 Aerosol, definition, 247.
 Agar, nutritive value, 591.
 Agar, thiamin content, 39.
 Aged people—
 emerging problems of, 878.
 vitamin requirements, Mass. 880.
 Aggridant, use of term, Me. 183.
 Agricultural —
 Adjustment Act of 1938, amended, U.S.D.A. 437.
 Adjustment Administration—
 program, popularity, Pa. 586.
 reports, U.S.D.A. 202.
 and rural life programs, farmers' attitudes toward, S.C. 445.
 books, American, selected list, U.S.D.A. 880.
 changes since 1917 in Knox County, Tenn. 444.
 chemistry, *see* Chemistry.
 colleges, organization list, U.S.D.A. 880.
 conservation program, effects and implications, Kans. 202.
 conservation programs, W.Va. 731.
 cooperation in Maryland, status and trend, Md. 873.

Agricultural—Continued.

- cycles, specific, relation to prices, Iowa 283.
- economics, sources of information for, 283.
- economics, statistical methods applied to, 283.
- economy of Thailand, U.S.D.A. 435.
- economy, post-war, transitions to, 582.
- education for beginning farmers, nature and extent of need for, Iowa 302.
- education, part-time, effectiveness, Iowa 302.
- engineering, *see* Engineering.
- engineers, training, problems in, 302.
- equipment for different crops, studies, Mo. 129.
- experiment stations, *see* Experiment station(s).
- extension, *see* Extension.
- journals, new, 756.
- labor—
 - as factor in agricultural production in 1942 and 1943, Okla. 867.
 - hired, under wage and hours regulation, 582.
 - in the first World War, 582.
 - in United States, U.S.D.A. 288.
 - requirements, seasonal, for California crops, forecast of, Calif. 868.
 - studies, Ind. 730.
 - unions, recent development among, 583.
 - utilization, Mo. 129.
- land, criteria for rating, comparisons, 867.
- leadership, source in Adair County, Iowa 300.
- machinery—*see also* Combine(s) and Thresher.
 - distribution by farmers' cooperative associations, U.S.D.A. 206.
 - for harvesting bluegrass seed, 432.
 - important, varieties and use, 430.
 - life, service, and cost of service, Iowa 133.
 - new, available assistance in adaptation, N.J. 428.
 - requirements for farming with crop residue mulch, 122.
- planning in world at war, U.S.D.A. 285.
- policy and nutritional science, 582.
- policy for hemisphere defense, 583.
- preparedness, U.S.D.A. 285.
- prices, high, reflected in higher farm income, Miss. 730.
- prices, relation to specific agricultural cycles, Iowa 283.
- produce market, Boston regional, Mass. 866.
- production—
 - goals for 1942, revised, Okla. 130.
 - greater, as defensive weapon in war, P.R.U. 435.
 - in 1942 and 1943, farm labor as factor in, Okla. 867.

Agricultural—Continued.

- products—
 - cost of production, effect of size of farm and type of power, Ill. 583.
 - during World Wars I and II, prices of, behavior, 582.
 - home-grown, used on Michigan farms, Mich. 322.
 - marketing, *see* Marketing.
 - tables on prices, price indexes, and indexes of purchasing power, Okla. 866.
 - tariff rates on, U.S.D.A. 289.
 - programs—
 - adapting for war needs, 582.
 - and social conflicts, 583.
 - for post-war period, 582.
 - pursuits, attitudes toward, development of scales to measure, Iowa 302.
 - raw products research activities, 471.
 - readjustments, post-war, Latin American aspects, 582.
 - relief, *see* Relief.
 - resources of Iowa, effects of governmental programs on, Iowa 283.
 - situation—
 - and price tables and indexes, Okla. 730.
 - current, fundamental elements in, 583.
 - review, Okla. 435, 866.
 - tenancy, *see* Farm tenancy, Farm tenure, and Land tenure.
 - wastes, use for farm building insulation, Iowa 277.
 - watersheds, tillage practices for erosion control and runoff, Wash. 343.
 - workers and social insurance, 582.
- Agriculture—
- and foreign trade, [N.Y.]Cornell 130.
 - Department of, *see* United States Department of Agriculture.
 - electricity in, *see* Electricity.
 - Inter-American Conference of, research at, 757.
 - interregional competition in, research, U.S.D.A. 286.
 - joint costs in, economics, 583.
 - of Arizona, supplies, prices, and income, Ariz. 130.
 - of Cuba, U.S.D.A. 284.
 - of Eastern Russia, effect of war on, U.S.D.A. 285.
 - of Ecuador, 755.
 - of Jamaica, U.S.D.A. 285.
 - present crisis and effects of World War I, U.S.D.A. 285.
 - problems of, in Yakima Valley, Wash. 436.
 - relation to National Defense program, U.S.D.A. 285.
 - southern, benefits from farm machinery in, 279.
 - southern, in a changing world, Miss. 159.
 - use of light in, Idaho 725.
 - wartime, engineering in, 572.

Agriculture.—Continued.

- wartime, land, labor, machines as key factors, 573.
- Agriolimax agrestis* and its environment, 820.
- Agriotes obscurus*, life history and habits, 253.
- Agromyza simplex*, see Asparagus miner.
- Agronomic studies, planning experimental fields for, Iowa 183.
- Agropyron* sp. seed germination, 512.
- Agrostis tenuis*, growth, effect of vitamin B₁, 194.
- Agrotis orthogonia*, see Cutworm, pale western.
- Air conditioning for houses in California, Calif. 729.
- Air movement, effect of shelterbelts, Ind. 677.
- Air permeability instrument for testing textiles, 753.
- Alabama argillacea*, see Cotton leafworm.
- Albinism in turkeys, sex-linked, 303.
- Albumin, egg—
raw, injury-producing protein in, concentration and assay, 619.
watery and thick, composition, Wash. 404.
- Alcohol(s)—
bactericidal activities, effect of temperature, 486.
tolerance of yeasts, 35.
- Alcoholic fermentation, formic acid formation in, 181.
- Aldehydes, synthesis, from Grignard reagents, 4.
- Aleurites trisperma*, culture, P.R. 668.
- Alfalfa—
advantages of clipping or pasturing part of crop at 3 to 6 in. high, Wis. 504.
alone v. alfalfa-grass mixtures, Iowa 212.
and bromegrass pasture, merits of, Wis. 504.
and bromegrass v. bluegrass pastures for dairy cattle, Ind. 704.
and grass combinations, Ky. 792.
and grass mixture on irrigated land, value, Colo. 214.
and red clover mixtures, Ky. 792.
bacterial wilt, Ariz. 805.
black stem studies, 811.
borax studies with, Mass. 793.
breeding, Ariz. 791, Idaho 659, Nebr. 662, Wash. 867.
carotene and riboflavin in, 555.
composition, Tenn. 327.
culture tests, Wash. 367, Wyo. 793.
cutting experiments, N.Mex. 366.
fertilizer tests, Ariz. 791, Ind. 659, N.J. 366, N.Mex. 366.
hay, first-, second-, and third-crop, nutritive values, Nev. 835.
hay, hexose-phosphate in, 473.
hay v. alfalfa-molasses silage for steers, Ky. 884.

Alfalfa—Continued.

- hay, variability in mineral nutrient content, Colo. 834.
- Insects, N.Dak. 248.
- Irrigation duty-of-water studies, N.Mex. 429.
- land in continuous cultivation, plant succession on, effect of fertilizer, U.S.D.A. 485.
- leaf meal, dehydrated, improvements in processing, 160.
- leaf meal, effect on egg production and hatchability, 840.
- leaf meal, lipides isolated from, Mich. 168.
- leaf spot in Pennsylvania, U.S.D.A. 681.
- leafhopper resistance, relation to strains, Ill. 545.
- leaves, large and small, morphological analysis, 651.
- liberal feeding to pigs, high returns from, Wis. 555.
- management, [N.Y.] Cornell 53.
- molasses silage v. alfalfa hay for steers, Ky. 834.
- mosaic virus, celery mosaic caused by, 538.
- pasture for pigs, supplemental feeds for, N.Dak. 836.
- percolation and water requirement studies, Oreg. 860.
- phosphate fertilizer experiments, N.Mex. 368.
- pollen, collection by bees, U.S.D.A. 88.
- seed production studies, Ariz. 791.
- seedling infection by *Pythium debaryanum*, Iowa 681.
- silage, see Silage.
- snout beetle, pellet bait for control, 832.
- snout beetle, studies, [N.Y.] Cornell 90.
- use for silage, Ill. 562.
- v. lespedeza as green feed for chicks, Tenn. 404.
- variety tests, Idaho, 659, Me. 213, N.Mex. 366, Wash. 367, Wyo. 793.
- variety tests on bacterial wilt-infested soil, Iowa 212.
- weevil, studies, U.S.D.A. 88.
- wilt control, N.J. 378.
- wilt or wilting, 229.
- wireworm population, effect of crop rotation, Idaho 694.
- witches'-broom disease, cause, Wash. 378.
- yields and production costs, Mo. 52.
- Alkali soil(s)—
reclamation, Wash. 343.
survival of micro-organisms in, 28.
- Alkaline-calcareous soils, available phosphate in, determination, Ariz. 768.
- Alkalinity of southern Idaho soils, factors affecting, Idaho 632.
- Allergy, review of literature, 566.
- Allium* white rot in Louisiana, U.S.D.A. 527.
- Almond moth, notes, 551.

- Alstroemeria pelegrina* as greenhouse ornamental, [N.Y.] Cornell 64.
- Alternaria**—
defoliation of tomatoes, Conn. [New Haven] 805.
solanii infection of tomato seedlings, 386.
- Aluminum requirements of beef cattle, Fla. 833.
- Alyceclover—
adaptation trial as hay crop, S.C. 367.
fertilizer tests, Fla. 791.
production tests, Fla. 791, Tenn. 367.
value as maintenance ration for beef cattle, Miss. 699.
- Amazon fly, two strains, introduction, liberation, and recovery, P.R. 695.
- American—
Association of Economic Entomologists, common names of insects approved by, 246.
Dairy Science Association, meeting, 612.
- A. S. T. M. Standards, 1941 Supplement, tentative standards, 726.
- Amide nitrogen as source of protein for chicks, 702.
- Amino acetates, high-molecular-weight aliphatic, germicidal properties, 34.
- Amino acid(s)—
amide glutamine, method for preparing, commercial application, Conn. [New Haven] 760.
comparative growth studies on, 778.
composition and tests of nutritive value, 744.
determination by ninhydrin reaction, 177.
in oats and oat milling products, 138.
studies, Conn. [New Haven] 760.
synthesis, by chick embryo, 698.
utilization, for growth in mice, 698.
- p*-Aminobenzoic acid—
anti-gray hair activity in nutritional achromotrichia of mice, 600.
effect on graying of rat fur, 751.
- Ammonia titration in presence of boric acid, 172.
- Amphicoema vulpina*, notes, Mass. 820.
- Amphidiploidy, incidence and significance, 786.
- Amphimallus mafalis (rufescens)*, new to United States, 822.
- Amphorophora alleni* n.sp., description, 548.
- Amsinckia intermedia*, poisonous constituents, Wash. 418.
- Amyl acetate as clearing agent for embryonic material, 629.
- β -amylase, activity, effects of buffers on, 168.
- Amylases, dextrinizing and liquefying functions, 472.
- Anabrus simplex*, see Cricket, Mormon.
- Anaesthesia, veterinary, 564.
- Analysis, chemical, see Chemical.
- Analytical methods, referees' reports, 329.
- Anasa tristis*, formation of tracheal funnel, 402.
- Anastrepha**—
ludens, see Fruitfly, Mexican.
mombinpraeoptans, see Fruitfly, West Indian.
suspensa, adult populations in citrus plantings in Puerto Rico, P.R. 96.
- Andrena perplexa*, notes, Del. 245.
- Androgen(s)—
assay, chick comb for, 365.
urinary excretion by boars of different lines of breeding, 657.
- Androgenic substances, early effects in rat by aid of colchicine, 211.
- Androsterone, response to, in immature male rat, 789.
- Anemia(s)—
etiology, 455.
in ascorbic acid deficiency and response to iron, 154.
in dogs due to pyridoxine deficiency, 570.
infectious equine, transmission of, 718.
nutritional, in poultry, Mo. 98.
nutritional, relation to composition of home-grown foods, Fla. 880.
of flexed-tailed mice, 497.
of infancy, round table discussion, 156.
pigeon, due to vitamin deficiency, Mo. 145.
severity, effect on rate of hemoglobin production, 896.
- Aneurin, see Vitamin B₁.
- Angleshades moth, life history, 551.
- Anguillulina**—
dipsaci, giant race of, on broad beans, 533.
pratensis, host specialization, 390.
pratensis, life history, 543.
- Animal(s)—see also Cattle, Livestock, Mammals, Sheep, etc.
and man, relation to environment, Me. 303.
and plants, diploid cell and diploidisation process in, criticism and rebuttal, 495.
breeding—see also specific animals.
application of genetics to, 495.
problems, application of genetic principles, 208.
relation to environmental conditions, 47.
differences in form and behavior, genetic and endocrine basis, 211.
diseases—see also specific diseases.
diagnoses, Ind. 709.
relation to vitamin A, 710.
- domestic—
Babesia infections of, chemotherapeutic action of 4:4'-diamidino tllbene in, 109.
growth and development, Mo. 265.
parasites of, 109.
physiology, 49.
- farm, nutritive value of proteins from various sources and urea, [N.Y.] Cornell, 99.

Animal(s)—Continued.

- fats, see Fat(s).**
game, parasites of, relation to those of domestic animals, Wyo. 851.
heat production, base value, Pa. 99, 554.
husbandry experiments, design, 97.
mineral requirements and vitamins, 258.
nutrition—
 chemistry of, and Liebig, 616.
 relation to minor elements, 491.
 vitamins in relation to, 401.
parasites, see Parasites.
pathology, treatise, 564.
production of uniform experimental, in stock colony, Iowa 303.
reproduction in—
 physiology of, 789.
 role of endocrine secretions and nutrients in, 258.
shelters, ventilation, Mo. 433.
species, heat increment of gestation and birth weight in, relation, Mo. 99.
tissues, collagen and elastin in, determination, rapid method for, Iowa 256.
tissues, nicotinic acid in, quantitative estimation, 14.
Annona species, insecticidal properties, 825.
Anobium magnum, new borer damaging timber, 399.
Anomogyna elimata larvae, new descriptions, 400.
Anopheles—*see also* Malaria and Mosquito(es).
 complex in California, 89.
 culicifacies in borrow pits, ecology of larvae, 402.
 pseudopunctipennis, vector of malaria in Mexico, 255.
Anorthite, weathering, colloidal organic acids as factors, 25.
Ant(s)—
 Argentine, in Hawaii, 553.
 Argentine, introduced into Australia, 97.
 baits, Ill. 546.
 exotic, introduced into Australia, 97.
 parasite, new, 403.
 Pharaoh, thermal preference, guide in control, 97.
 white, see Termite(s).
Antelope—
 American, new coccidium from, 418.
 placentation of, 361.
Anthocyanins, chemistry of, 4.
Anthrenus—
 eugenii, *see* Pepper weevil.
 grandis, *see* Boll weevil.
 grandis thurberiae, *see* Thurberia weevil.
 signatus, *see* Strawberry weevil.
Antrenus—
 scrophulariae, *see* Carpet beetle.
 verbasci, *see* Carpet beetle, varied.
 vorus, biology, [N.Y.] Cornell 94.

Antiseptics, effect on soil processes, N.J. 342.

Anuraphis—

- padi* control with dinitroresol, 396.
roseus, *see* Apple aphid, rosy.
Aonidiella (Chrysomphalus) aurantii, *see* Red scale, California.
Apanteles machaeralis, biology and morphology, 395.
Apatolestes species west of Mississippi River, 402.
Aphelenchoides ritzema-bosi in tomato fruit, 539.
Aphididae new to island of Midway, 547.

Aphids—

- Florida, biology and control, Fla. 822.
insecticide blends for, Wis. 516.
leaf and root, studies, U.S.D.A. 88.
population of potato crops in Ireland, relation to seed potato production, 399.
relation to spread of potato virus diseases, Me. 248.
spray mix for, Pa. 546.
taken on grass in Utah, 548.
woolly, *see* Apple aphid, woolly.

Aphis—

- (*Doralis*) *fabae* and *Aphis (Doralis) rumicis*, comparison, 548.
pomi, *see* Apple aphid.
rhmani, vector of potato virus Y, 829.
rumicis, *see* Bean aphid.

Aphrophora parallela, *see* Pine splitle bug.
Aplastomorpha calandrac, parasite on cigarette beetle larvae, 823.

Apparatus—

- for counting nematode eggs in feces, 392.
for cutting tissue sections, 359, 627.
for determination of organic acids in plant sap, 783.
for determining viability of embryonated helminth ova, 392.
for heavy water purification, pycnometer for, 474.
for measurement of bread crumb deformation, 475.
for microevaporations, 331.
for preparation of suspensions of feces for helminthological examinations, 392.
for production of artificial frost injury in plant tissues, 67.
for quantitative catalytic microhydrogenation, 170.
for simultaneous measurement of CO₂ and organic volatiles in internal atmosphere of fruits and vegetables, 57.
for sorption measurements under partial vacuum, description, 170.
for studying settling rate and fractionation of dusts, 68.
improved methoxyl, 475.
improved sublimation, 474.
laboratory spraying, for study of contact insecticides, 87.
molecular still heads, designs for, 474.

Apple(s)—

- and raspberry juice, demonstration sale, 17.
- annual bearing, effect of blossom-spray and fruit-thinning practices, [N.Y.] Cornell 61.
- aphid control with dinitrocresol, 396.
- aphid, rosy, control, Tenn. 393.
- aphid, rosy, outbreak, Ill. 546.
- aphid, woolly—
 - biology and control, 93.
 - infesting apple cores, 821.
- arsenical injury, control, 815.
- bacterial fire blight, Iowa 228.
- biennial bearing, control, Mo. 57.
- bitter rot control, copper sprays compared, Del. 227.
- blossom blight, tabulation, U.S.D.A. 805.
- blossom sprays for reducing and harvest sprays for increasing yields, 672.
- blotch control, Mo. 67.
- bordeaux cheapest and most dependable spray for, Ill. 528.
- branches, performance, relation to age, Mo. 57.
- breeding, Ill. 516, Iowa 220, Me. 220.

Aster(s)—

- China, *Fusarium* wilt of, Ind. 679.
- leafhopper, control, [N.Y.] Cornell 90.
- leafhopper, studies, U.S.D.A. 88.
- leafhoppers, daily flight, 548.
- variety tests, Pa. 513.
- yellow in periwinkles, heat cure, 83.

Astragalus pectinatus, crystalline amino acid complex containing selenium and sulfur from, 200.**Astragalus, selenium indicator species, identification, 711.****Atmospheric haze, filters for penetrating, 679.****Attagenus piceus, see Carpet beetle, black.**

Autographa spp., larvae, new descriptions, 400.

Auxin(s)—

- determination in plants, 351.
- in American soils, 344.
- in plant materials, isolation and identification, 778.
- in soils, extraction and assay, 186.
- interactions in growth and inhibition, 778.
- pea test for, nastic and traumatic causes of curvatures in, 488.
- transport in inverted Tagetes cuttings, polarity, 38.

Avena—

- fatua* injured seeds, viability, 512.
- sp., inoculations with races and collections of *Ustilago* spp., Wash. 378.

Avidin in raw egg white, concentration and assay, 619.

Avocado(s)—

- and oak root fungus, 241.
- culture, Fla., 799.
- diseases, Fla. 806.
- Fuerte, climacteric rise in respiration rate, 521.
- selection and propagation, P.R.U. 221.
- sun blotch, nature and control, 241.
- trees, young, root distribution on bench terraces, 674.
- trunk cankers, 241.

Axonopus compressus seed germination, effect of different temperatures, 512.

Azalea(s)—

- culture, N.J. 371.
- diseases, new, in Gulf coast area, 245.
- flower spot fungus, Spanish moss mulch for control, 243.
- flower spot spread, relation to insects, U.S.D.A. 243.
- Orullnia* flower spot, Fla. 806.

Azotobacter—

- activity in New Jersey soils, lack of, N.J. 342.
- agile*, growth, effect of copper and iodine, 491.
- cells, large scale production, 33.
- chroococcum*, inoculation of soil with, 637.
- cultures, hydrogenase in, 195.
- growth in soil, factors affecting, 52.
- hydrogenase in, properties, 33.

Babcock test, review of literature, 707.

Babesia—

- canis* infection of dogs, treatment with 4:4'-diamidino diphenoxy propane, 118.
- infections of domestic animals, chemotherapeutic action of 4:4'-diamidino stilbene in, 109.

Baby beef, *see* Cattle, baby beef.

Bacilli—

- aerobic sporulating, bactericidal substances, 84.
- grown on three types of peptone, variability in acid and alkali production, 83.

Bacillus—

abortus, *see* *Brucella abortus* and Bang's disease.

albolactis in Virginia milk, effect on quality, 413.

anthracis, longevity of dry spores, 418.

coli, effect of sulfonamide derivatives, 564.

macerans, amylases produced by, preparation and properties, 485.

mycoides, lethal effect of drier rolls on, 348.

polymyza, amylases produced by, preparation and properties, 485.

Bacon pig, nutrition of, 406.

Bacteria—

aerobic mesophilic, fermentation of cellulose by, 636.

aerobic, vegetative and spore cells, spectrochemical analysis, 33.

aging without reproduction and viability of young cells, 776.

and fungi, antibiosis between studies, 486.

autotrophic sulfur, growth substances in cells of, 33.

cryophilic, cause of milk samples failing the methylene blue test, 847.

dehydrogenase systems of, [N.Y.]Cornell 33.

destruction of germicides, effect of vacuum, 34.

effect of carbon dioxide on, Mich. 258.

gram-negative, new bactericidal agent active against, 348.

green - fluorescent - pigment - producing, [N.Y.]Cornell 33.

heterotrophic, assimilation of heavy carbon dioxide by, 348.

in creamery well water, N.Dak. 707.

in milk and soil, *see* Milk and Soil(s).

in mucous membranes and viscera of rats, effect of chronic vitamin A deficiency, 599.

in well waters, 106.

lethal effect of drier rolls on, 181, 348.

metabolism of, 35.

mutation in, 44.

nitrogen and accessory growth factor requirements, Iowa 191.

nuclear apparatus of, 349.

phytopathogenic—

lipolytic activity determined by spirit blue agar and its taxonomic significance, 809.

nomenclature, classification, and physiology, [N.Y.]Cornell 67.

sporiferous, variability, [N.Y.]Cornell 83.

staining reactions, 630.

staining with acid dyes, 630.

utilization of hydrocarbons by, 83.

Bacterial—

metabolism, aldolase and isomerase equilibria in, 35.

nucleus, demonstration of, [N.Y.]Cornell, 33.

Bacterial—Continued.

- spores in fluids, killing by agitation with small abrasives, 192.
- Bacteriological culture media, *see* Culture media.
- Bacteriological technic, report of committee on, 34.
- Bacteriologists, Society of American, local branches, proceedings, 229.

- Bacteriostasis, mechanism, relation to *p*-aminobenzoic acid, 271.

Bacterium—

- citri*, *see* Citrus canker.
- coli*, *see* *Escherichia coli*.
- papavericola* on poppy in Oregon, U.S. D.A. 805.
- purificans*, notes, 716.
- Balcones escarpment, floral distribution, 32.
- Baler, pick-up, and haymaker, [N.Y.]Cornell 120.
- Balsamroot, arrowleaf, feeding value, effect of stage of maturity, Idaho 616.

Bamboo(s)—

- new, from Venezuela and Colombia, 777.
- powder-post beetle, biological studies and control, P.R. 695.
- propagation and utilization, P.R. 608.
- scale predators, redistribution to new localities, P.R. 695.
- scales, coccinellids predatory on, collection in Trinidad and Brazil, 89.
- scales, lady beetles effective against, P.R. 695.
- wood, moisture in, reduction with experimental solar drier, P.R. 725.

Banana—

- carbohydrate metabolism during storage and ripening, 63.
- cercospora* leaf disease control, 241.
- Chitoclybe* root rot, 542.
- virus disease, 81.

Bang's disease—*see also* Brucellosis.

- calfhood vaccination against, 421, 567.
- control, Utah 713.
- in Ontario, control by area plan, 566.
- studies, Ill. 564, N.J. 418.
- tests, tube agglutination and rapid or plate, Mo. 108.
- transmission from swine to cattle, Mo. 108.

Barberry eradication for wheat stem rust control, U.S.D.A. 66.**Barium adsorption by soils and minerals, relation to pH, 642.****Bark beetle(s)—**

- and apple trees, relation to Dutch elm disease control program, 550.
- of Washington, 400.
- surveys and control, U.S.D.A. 88.

Barley—

- activity and quality (Q_{10} and μ) of catalase in, 489.

Barley—Continued.

- adaptation to lowland soils and production methods, Mo. 213.
- ascorbic acid system in, 351.
- and air movement in, Ind. 725.
- breeding, Idaho 659, 679, Iowa 212, Mo. 52, N.J. 366, N.Mex. 366, [N.Y.]Cornell 53, S.Dak. 504, Tenn. 367, Wash. 367.
- culture tests, Tenn. 367, Wyo. 793.
- development, effect of photoperiod and temperature, 40.
- fertility in lateral spikelets, inheritance, 786.
- for fattening cattle, Mo. 99.
- growth and yield, effect of diseases, Idaho 679.
- harvesting, combine v. binder-separator, Mich. 795.
- insects bred from, 394.
- lespedeza v. soybeans sown in, Tenn. 367.
- loose smut resistance, inheritance of, 532.
- male-sterile, for study of floral infection, 382.
- malts, starch degrading properties, 472.
- manganese deficiency control by spraying, 229.
- mechanical injury in threshing, 578.
- mechanical injury to, prevention, S.Dak. 573.
- roots, absorption and excretion of K and Ca in culture media, Mass. 792.
- root cells, accumulation of monovalent ions by, effects of Cu and other divalent ions, 646.
- roots, excised, metabolism of organic acids in, 491.
- rotation studies, Va. 793.
- seed weight, effect of flower mutilation, Ill. 504.
- seedling root tips, photodynamic action of neutral red on, 493.
- seedlings, respiration, relation to oxygen supply, 31.
- smut, nonpathogenic buff-colored, 811.
- smut resistance, variety tests for, 229.
- smut, seed treatment for, Mo. 67.
- spring, in Illinois, Ill. 368.
- spring, place in New Jersey farming, N.J. 366.
- straw, digestibility and feeding value for horses, effect of Beckmann's treatment, 407.
- time of planting tests, Me. 213.
- Ustilago nuda* in, resistance inheritance to, Mo. 67.
- varieties, Mo. 214.
- variety tests, Del. 212, Idaho 659, Ill. 504, Iowa 212, Mo. 52, N.J. 366, N.Mex. 366, Pa. 504, S.C. 367, S.Dak. 504, Tenn. 367, Wash. 367, Wyo. 793.
- winter, feeding value for pigs, N.J. 403.
- winter, preferred breeding ground for chinch bugs, Ill. 546.
- yield and composition, Ariz. 841.
- yield and production costs, Mo. 53.

Barn(s)—

- construction, factors in, N.J. 410.
- dairy, concrete, temperature, humidity, dairy, insulation, prevention of condensation loading, N.J. 428.
- pen, methods of building, Wis. 574.

Bases, exchangeable, determination, Tenn. 343.

Basiporum gallarum pathogenicity to corn, Iowa 228.

Bassus stigmaterus, parasite of sugarcane borer in Florida, 95.

Bat infestations in human dwellings in Brazil and *Ornithodoros tulaje*, 403.

Bat, Jamaican, placentation of, 499.

Bay leaves, distilling, use of salt in, 180.

Bay oil, yield and quality, increase, and properties, P.R. 617.

Beam, curved, stresses in under loads normal to plane of axis, 576.

Bean(s)—*see also* Mung bean(s) and Soybean(s).

- anthracnose resistance, factorial interpretation, U.S.D.A. 682.

- anthracnose severe in Virginia, U.S.D.A. 805.

- anthracnose, varietal susceptibility, 529.

- aphid, description and comparison with *Aphis (Doralis) fabae*, 548.

- bacterial blight, N.J. 815.

- metabolism hormone, Mo. 103.

Carbon—

- black, use to activate early tobacco growth, Conn.[New Haven] 797.

dioxide—

- absorption, inexpensive vessel for, 42.

- depressant effect on photosynthesis, 202.

- detection from mixtures of carbonates and sulfites, 177.

- heterotrophic assimilation by bacteria and by animal tissue, 192.

- heterotrophic, assimilation, heavy carbon as tracer, 166.

- in blood and other fluids, determination, 177.

- radioactive, use in photosynthesis, 485.

- utilization, radioactive carbon as indicator, 202.

- in soils under different soil treatment, Mo. 22.

- monoxide in blood, determination, 177.

- organic, of soils, effect of rotation and fertilizer treatments, N.H. 344.

- Carbonate determination, rapid procedure, 177.

Carnation(s)—

- disease resistance and heredity in, Mass. 800, 807.

- electric light for, 278.

- flowers, splitting, effect of K on, Ill. 523.

- greenhouse, thrips as pests, Wash. 394.

- nutritional symptoms in, 225.

- soils, Hmng, Mass. 800.

- verticilliose, 243.

- virus yellows, Wash. 378.

- wilt and root rot, cause, 69.

Carotene—

- alfalfa v. lespedeza feeds as source, S.C. 403.

- and vitamin A absorption by chickens, relation to lecithin, N.J. 403.

- determination, developments in methods, 7.

- extraction from plant material, 763.

- in alfalfa meal, determination methods, 7.

- in blood and milk of cows, effect of high vitamin A intake, 844.

- in blood plasma of dairy cattle, relation to vitamin A deficiency, 844.

- in carrot, cytological study, 200.

- in dehydrated alfalfa meal, retarding destruction by ground raw soybeans, Idaho 616.

- in grass mixtures for feed, 257.

- in leaves, determination, 337.

- in rations of dairy cows, relative availability, Ind. 704.

Carotene—Continued.

in wheat harvested at successive stages, 200.

in whole-wheat flour and bread, 145.

in yellow corn, determination, 8.

injected, and vitamin A, comparative physiologic value, 892.

intake relation to blood carotene values of dairy cattle, 410.

Carotenoid pigments—

and content of corn grains, Ind. 616.

and content of vegetables, Ind. 616.

bacterial, isolation, and determination of absorption spectrum maxima, 33.

isomerization of, 485.

Carotenoids—

Carr-Price reaction, significance to chemical measurement of vitamin A, 479.

chemistry of, 4.

human excretion of, 749.

of watermelon, 312.

Carp, raw, feeding to chicks, inactivation of vitamin B₁₂ by, 702.

Carpet beetle—

biology, [N.Y.]Cornell 95.

black, biology, [N.Y.]Cornell 94.

black, two species, 821.

evaluating protection of fabrics from, 825.

studies, 549.

varied, biology, [N.Y.]Cornell 94.

Carpet grass pastures, establishing and maintaining annual clovers in, S.C. 367.

Carpocapsa pomonella, see Codling moth.

Carrot(s)—

calcium in, utilization by adults, 889.

calcium, phosphorus, and iron in, range of, Ariz. 880.

carotene in, cytological study, 200.

culture of cambial tissue, 196.

culture tests, Fla. 799.

dried, ascorbic acid in, 751.

rots, prevention by low storage temperatures, Idaho 679.

seed treatments recommended for, N.Y. State 222.

variety tests, Fla. 799.

weevil control, N.J. 695.

Caseln—

as source of protein for chicks, 702.

fiber determination, 753.

iodinated, thyroidal activity, effect of progressive iodination on, 267.

Cassava variety tests, P.R.U. 213.

Cassava wilt, cause, 69.

Castor-bean(s)—

production tests, P.R.U. 213

sheller, new, Tenn. 728.

shelling, 125.

thresher, home-made, 579.

variety tests, Ariz. 791, Ky. 702.

Castration, effect on feather weight in fowls, 790.

Cat(s)—

deaf white, three generations of, 361.

Cat(s)—Continued.

fetal, newborn, and adult, heart and lung weight, 655.

prenatal growth, 50.

Catalase, chemical nature, 471.

Cataract—

in rats on flavin-deficient diets, Mo. 145.

nutritional, cause and control, Mass. 880.

Catorama neltumae, new beetle from Puerto Rico, from mesquite seed pods, P.R.U. 400.

Catsup, vitamin C in, Mass. 760.

Cattle—see also Calf(ves), Cow(s), Heifer(s), Livestock, and Steers.

artificial breeding, four years of, results, 104.

baby beef, economical production, S.Dak. 554.

balance experiments, correction of heat production for changes in live weight, 555.

barley and corn for fattening, Mo. 99.

beef—

Alyceclover and lespedeza as hay crops for wintering, Miss. 609.

copper, cobalt, and aluminum requirements, Fla. 833.

feed crop production and utilization, Fla. 833.

feeding experiments with alfalfa hay, Nev. 835.

grazing tests with Napier grass, Fla. 833.

live-weight gains, effect of grazing method, Mo. 53.

milk secretion, effect of thyroxine, Ind. 655.

pasture studies on Everglades soils, Fla. 833.

production, rotation pastures v. permanent pastures for, Ind. 659.

record of performance tests, discussion of feeding period in, 98.

use of pastures receiving different treatments, S.C. 403.

wintering, 98.

wintering, rations compared, Fla. 833.

beef-cow herds, returns from, Ky. 866.

blood analysis of, Ariz. 760.

blood chemistry during oestral cycle, 212.

chromosome counts, Mo. 47.

cobalt and copper supplied by forage, Fla. 833.

continuous rotation and supplemental grazing on bluegrass pastures, Mo. 98.

dairy—

alfalfa-bromegrass v. bluegrass pastures for, Ind. 704.

birth weight, growth rate, and type, effect of inbreeding, 208, 410.

blood carotene, relation to carotene intake by, 410.

carotene in blood plasma, relation to vitamin A deficiency, 844.

electrocardiograph studies, 846.

Cattle—Continued.

dairy—continued.

- enterprise, profitableness in various regions, P.R.U. 284.
- experimental breeding for Tropics, 788.
- fermentation energy losses in, Mo. 103.
- for economical production, improving, 104.
- heavy grain feeding, economy of, Pa. 562.
- normal growth, Ariz. 841.
- nutrition, minerals in, 705.
- nutritional deficiencies, 104.
- peanut meal for, 410.
- repeatability of type ratings in, 264.
- diseases, *see specific diseases*.
- endoparasites, treatment and prevention, U.S.D.A. 112.
- energy metabolism, Pa. 99.
- falling disease and copper deficiency, 568.
- fattening, Atlas sorgo v. corn silage for, Ind. 697.
- fattening, first and third cuttings of alfalfa hay with cottonseed hulls for, N.Mex. 403.
- feed, lemon grass residue as, P.R. 617.
- feed, production, rotation pastures v. cultivated crops, Mo. 53, 99.
- feeder, shipped into Minnesota, Minn. 732.
- feeding, commercial, cost data, Iowa 283.
- feeding methods of Iowa farmers, Iowa 132.
- feeding test with Coes sorghum grain, Colo. 835.
- giving low titer reactions to Bang's agglutination test, studies, Mo. 108.
- grazing on range land, relation to vegetative composition, Nebr. 506.
- grubs, control, dry cube or derris with wettable sulfur for, 247.
- grubs, control with power sprayers, 247.
- grubs, studies, U.S.D.A. 89.
- Guernseys and Jerseys, history, 264.
- herd management, experimental, Calif. 698.
- herds free from Bang's disease reactors, abortion and sterility in, Ind. 710.
- Hereford, large and small type, studies, Mont. 555.
- Hereford, record of performance, Mont. 360.
- Holstein-Friesian, effect of inbreeding, Iowa 209.
- horned, shipping, benefit of horn-tipping, Miss. 405.
- introduction into Colonial North America, 264.
- Jersey, breeding studies in station herd, Mo. 47.
- Jersey, resting energy metabolism and ventilation rate relation to body weight, Mo. 265.

Cattle—Continued.

- Jersey v. Holstein, efficiency in utilizing vitamin D in rations, S.Dak. 563.
 - Kee, studies, Ill. 546, U.S.D.A. 89.
 - longevity of vacinia immunity in, 853.
 - metabolism stalls for, 704.
 - of European breeds, suitability of white highlands of Kenya for, 209.
 - of unknown age, estimating live weight from chest girth, Mo. 103.
 - *on ranches, financial and physical data, N.Mex. 435.
 - parasites, notes, P.R.U. 270.
 - physiological and gravitational weight, relation, Mo. 103.
 - poisoning—*see also* plant(s), poisonous, and specific plants.
 - from cloak fern, Tex. 505.
 - ranches, livestock production and intensity of grazing, N.Mex. 435.
 - range, growth and production factors in, Mont. 556.
 - range, treatment for warbles, Ariz. 851.
 - rations, deficiencies in calcium and phosphorus, Wyo. 831.
 - reproductive efficiency, method of determining, 496.
 - salting and watering habits, automatic recording, 405.
 - scale of heat tolerance for, 98.
 - Shorthorn Bluebloods, purchase by college, Utah 323.
 - sterility in, hormones for combating, [N.Y.]Cornell 47.
 - tested with mammalian and avian tuberculosis, determining sensitizing agent, 114.
 - ticks, *see* Tick(s).
 - two year-old, finishing, corn of different types compared, Tenn. 699.
 - weight gains, effect of weeds and shrubs in grass pasture, Colo. 258.
 - Zebu (Brahman) cross, possibilities in North Australia, 48.
- Cauliflower—
- boron nutrition, relation to browning, [N.Y.]Cornell 537.
 - calcium of, utilization, 143.
 - club root control, [N.Y.]Cornell 67.
 - dried, ascorbic acid in, 751.
 - growth, effect of vitamins, 39.
- Cedar(s)—
- eastern red, producing seedlings of, Okla. 677.
 - Ozark white, for upper Mississippi region, 525.
 - red, control of cedar-apple rust on, 79.
 - rust, *see* Apple rust.
 - white, bluestaining fungus in heartwood, 693.
 - white, *Phomopsis juniperovora* blight of, 229.
- Celery—
- blights, control, Fla. 806.
 - breeding, [N.Y.]Cornell 57.

Celery—Continued.

- carrot weevil as serious pest, biology and control, N.J. 696.
- diseases, seed and seedbed treatments, Fla. 806.
- grown on peat soil, use of copper and boron for, Wis. 513.
- late blight in Argentina, 538.
- mosaic caused by alfalfa mosaic virus, 538.
- soil, fertilizer, and variety studies, Fla. 799.
- spraying experiments, 538.
- stalk worm, life history and habits, 401.
- vapo-dusting, Fla. 806.
- Cell-nuclear size, regularity of, relation to growth and maturity of plants, 650.
- Cell vacuoles of Zn-deficient plants, spherical inclusions in, 809.
- Cellular metabolism, role of CO₂ in, 202.
- Cellulose—

- action of light on, 176.
- action of mesophilic bacteria on, 636.
- in layers of tracheids, orientation, significance of X rays in study, 493.
- new microchemical reaction for, 336.
- structure, revealed by optical and X-ray methods, 204.

Centaurea cyanus, *Sclerotinia* stem rot on, Mo. 67.

Cephalosporium—

- acremonium*, mode of entrance into corn ears, 383.

dieffenbachiae n sp., description, 82.

Cerambycidae of North America, origin and distribution, 89.

Ceratitis capitata, see Fruitfly, Mediterranean.

Ceratostomella—

- spp., wood-staining, temperature, moisture, and penetration studies, U.S.D.A. 84.

ulmi, reactivation in occluded infections and contamination of *Scolytus multistriatus*, 833.

ulmi, toxin formation by, 693.

vitamin deficiencies of, 350.

Ceroospora—

- capsici* lesions on pepper, new species of fungus attacking, 238.

leaf spot of peanuts, control, 67.

n.spp. in United States, U.S.D.A. 680.

new leaf-parasitizing species, 807.

sesami, notes, S.C. 378.

sebrina from red clover seed, 683.

Ceroosporella—

- leaf spot of privet, 229.

poagens n.sp., notes, 682.

Cereal(s)—see also Grain(s) and specific grains.

diseases, U.S.D.A. 805.

diseases in Kansas, U.S.D.A. 527, 680.

grain production by combine harvester and hammer mill, encouragement, Me. 280.

Cereal(s)—Continued.

grass, dried, effect on egg production and hatchability, 840.

grass juice for rabbits, Mo. 98.

in Canada, seed-borne fungi on, 532.

iron in, 475.

milling products, distribution of vitamin E in, 154.

parasitic fungi on, U.S.D.A. 680.

powdery mildews, 229.

products, nicotinic acid in, determination, 13.

riboflavin, analysis of, 621.

rusts, effect of light and temperature on viability of urediospores, 810.

rusts, reports, U.S.D.A. 680.

starch and crude fiber, digestion by minks and foxes, 407.

stored, insects, control, U.S.D.A. 88.

thiamin in, thiochrome method of analysis, 9.

Cerebella genus, biologic status and use, 807.

Cercia bubalus, see Buffalo treehopper.

Chabertia ovina in sheep on irrigated pastures, Oreg. 856.

Chalaropsis thielavioides on Chinese elm, 389.

Chalcidoidea, new species, descriptions, 402.

Chalcodermus aeneus, see Cowpea curculio.

Chamaecyparis root rot, 381.

Changa—

Larva parasites of, 97.

on cigar-type tobacco in South, U.S.D.A. 394.

parasite, establishment, P.R.U. 248.

Chaoborus astiotopus, see Gnat, Clear Lake.

Charcoal—

kiln, portable, studies, Conn.[New Haven] 860.

rot on potatoes in Illinois, U.S.D.A. 377.

Cheese—

American, manufactured from pasteurized milk, 107.

and butter cultures, mechanism of dissimulation of carbon sources in, Iowa 263.

blue mold, curing, use of mountain tunnel for, S.C. 411.

brick, bacteria in during ripening, 413.

brick, bacteriology, 708.

canning for storage, Wash. 411.

Cheddar—

American, practical moisture test for, Mich. 762.

and blue, ripening, role of lipolytic enzymes in, Iowa 263.

inhibiting mold growth in, Pa. 563.

rancidity development in, 108, Idaho 703.

reversibility of oxidative inactivation of milk lipase in, 269.

ripened, white particles found on, 270.

Cornhusker, manufacture, Nebr. 850.

cottage, preservation, N.Dak. 708.

defects and diseases, 413.

Cheese—Continued.

- foreign-type, effect of pasteurization of milk for, 161.
- foreign varieties, manufacture, ripening, and development, Wash. 411.
- Limburger, manufacturing processes, N.Y.State 270.
- makers, improved practices for, 850.
- measuring physical properties, devices for, 416.
- skipper, pyrethrum-sesame oil aerosol used against, 821.
- starters in New Zealand, progress and present position of research, 850.
- Swiss, gassy, micro-organisms associated with, 413.
- varieties suitable to Washington conditions, development, Wash. 411.

Chelonus annulipes, breeding on Mediterranean flour moth, methods, U.S.D.A. 254.

Chemical—

- analysis, instrumental methods, 474.
- research, agricultural, Liebig's influence in promotion, 616.

Chemistry, agricultural, century of progress in, 616.

Cherry(les)—

- and their hybrids, chromosomes and fertility, 45.
- bacterial gummosis, Idaho 679.
- banded chlorosis, 816.
- brown rot control, new fungicide for, 531.
- buckskin disease in Oregon, U.S.D.A. 377.
- cost of production, [N.Y.]Cornell 129.
- cuttings, use of growth substances for, Pa. 513.
- diseases in Ozark section of Arkansas, U.S.D.A. 66.
- effect of low winter temperatures, Ill. 516.
- flowering, virus disease of, 388.
- fruitworm, life history and control, Wash. 394.
- leaf spot control, 240, Ill. 528, Wis. 528.
- little disease and virus nature, 528.
- mahaleb, value as understock, Ill. 516.
- maraschino, dyeing with erythrosine, 18.
- Montmorency, concentration of growth hormone and fruitfulness in, 673.
- nursery stock, annual bacterial canker of, Mo. 67.
- orchards, soil management, Pa. 513.
- pollen-tube growth studies in, 45.
- powdery mildew, U.S.D.A. 805.
- rasp-leaf, notes, 240, Colo. 691.
- rootstocks for, Pa. 513.
- sand, susceptibility to brown rot, leaf spot, and plum pocket, S.Dak. 528.
- sour, production, factors affecting, Colo. 519.
- sour, yellows, a virus disease, Wis. 528.
- viruses, U.S.D.A. 805.
- yellows, trade role in control, 816.

Chestnut blight-resistant timber type, breeding for, 83.

Cheyletus mites on tobacco moth, 823.

Chick(s)—

- absorption and disposition of glucose in, 838.
- Barred Plymouth Rock, sexing method, Mass. 789.
- Barred Rock, growth of, Tenn. 701.
- battery brooder, minerals in rations of, 561.
- battery management in Hawaii, Hawaii 701.
- biotin and scaly dermatosis of, 703.
- brooder, diseases of, 719.
- brooding, electric, Mass. 837.
- brooding, electric, in winter, engineering aspects, 434.
- brooding, use of electricity in, Ind. 725.
- carbohydrate levels, effect of hormones, 790.
- cervical vertebrae in, embryology, 655.
- curled-toe paralysis and growth in, relation to riboflavin, 262.
- day-old, gizzard lesions in, 275, 561.
- day-old, sexing methods, N.J. 360, 658.
- diet, protein sources in, 408.
- effect of ultraviolet irradiation, Ind. 698.
- electric brooding under winter conditions, Pa. 102.
- embryo, synthesis of amino acids by, 698.
- gizzard erosion in, growth rate as factor, 262.
- glycine requirement, 838.
- green feeds for, comparison, Tenn. 404.
- growing, feeding, and management, Iowa 837.
- growth, effect of electric lights, Ind. 698.
- growth on skim milk powder but no green feed, N.J. 403.
- growth rate relation to size of thymus and bursa *Fabricius*, 263.
- growth variability, effects of nutrition, 559.
- induction of mating behavior following injection of sex hormones, 365.
- infected with tapeworm, growth rate effect of protein diet, 263.
- magnesium requirement, 839.
- manganese availability, effect of mineral supplements, 274.
- nonpathogenicity of western equine encephalomyelitis virus for, 274.
- nutrition, biotin in, 409.
- nutrition, choline and yeast in, 560.
- pantothenic acid requirement, 409.
- protein sources for, comparison, Miss. 702.
- raising in Oklahoma, Okla. 102.
- range or succulent feeds for, Ohio 559.
- ration with soybean meal, fish meal, and dried whey, development, Wash. 404.
- rations, effect of increased and reduced protein in, Ind. 698.
- respiratory disease of, 275.

Chick(s)—Continued.

- riboflavin-deficient, metabolism and food utilization, 839.
- simplified rations for, Mo. 98.
- slipped tendon in, *see* Perosis.
- soybean meal and corn substitution for bran and middlings, Ind. 698.
- treatment with radiant energy and effect on fowl leucosis, Iowa 270.
- twin, viable, 211.
- utilization of carotene by, S.C. 403.
- vitality, effect of breeding, N.J. 701.
- vitamin A and carotene in livers and blood, effect of ethyl alcohol and cresol, 261.
- vitamin B₆ requirement, 839.
- vitamin K deficient, effect of administration of hesperidin, ascorbic acid, and massive doses of vitamin D to, 560.

White Leghorn, variations in down color, insignificance, 49.

Chicken(s)—*see also* Chick(s), Fowl(s), Hens, Poultry, *etc.*

- broiler, corn substitutes in rations, Ind. 698.
- broilers and fryers of Del-Mar-Va and Virginia, grade and price comparisons, 586.
- dressed broilers held at 1.7° C., palatability and histological changes, 881.
- feathers, lanthionine isolation from, 166.
- lice, effect of sulfur on body populations, Fla. 851.
- nicotinic acid in, 150.
- roaster sized, "freezer burn" prevention, Mich. 764.

Chickpea—

- foot rot cause, 232.
- resistance to blight disease, determination, 232.

Child(ren)—*see also* Girls and Infants.

- ascorbic acid in plasma before and after dietetic adjustment, 152.
- diabetic, under good control, effect of adding vitamin B complex to diet, 601.
- energy metabolism, effect of tea, 888.
- from different economic levels in Chicago, physical fitness, 888.
- growth and bone development, relation to calcium, phosphorus, and nitrogen retention, 595.
- health and Selective Service physical standards, 311.
- high school, dark adaptation at different income levels, 743.
- in selected communities, food habits and nutritional status, Me. 302.
- Negro school, prevalence of dirt or clay eating, 889.
- preschool, magnesium needs, 596.
- school, hemoglobin and vitamin in blood of, S.C. 455.
- school, vitamin C nutrition in, 316, Me. 316.

Chilo plejadellus, *see* Rice stalk borer.

Chlorocorus cacti, notes, P.R. 695.

Chinch bug—

- abundance at Lawton, Okla., effect of weather conditions, 548.
- biometrics and control, Iowa 248.
- control, U.S.D.A. 88.
- injury, varietal resistance of sorghum to, Okla. 617.
- preferred breeding ground for, Ill. 546.
- Chinchillas, *Salmonella typhimurium* infections in, bacterin treatment, 118.
- Chionaspis furfura*, *see* Scurfy scale.

Chlorella—

- photosynthesis in, inhibitory effects of inorganic compounds, 493.
- vulgaris*, growth-inhibitor formed by, properties, 32.
- vulgaris*, rate of photosynthesis, relation to carbon dioxide concentration, 31.

Chlorides, accumulation by plant cells and relation to respiration, 201.

Chlorine, review of literature, 192.

Chlorochroa sayi, *see* Stinkbug, Say.

Chlorophyll(s)—

- a and b, analysis of plant extracts for, 333, 619.
- chemistry of, 4.
- components, number of, 41.
- in green leaves and iron, 356.
- in wheat harvested at successive stages, 200.
- solutions, absorption of light by, 41.
- spectroscopy of, Ind. 616.

Chlorophyll-protein complex, electrophoresis, 203.

Chloropidae of World, genotypes, list, 256.

Chloroplast(s)—

- granules, composition, relation to structure, 493.
- isolated, oxygen production by, 32.

Chlorosis—

- control in cottonwood trees and other plants, Wyo. 692.
- in Concord grape, effect of root on, 542.
- in ornamental figs, Fla. 799.
- in pin oaks, control, N.J. 378.

Chocolate milk, bacteriology, Mass. 760.

Chocolate sirups, bacteriology, Mass. 760.

Chokecherry, X-disease, [N.Y.] Cornell 68.

Cholesterol determination, new method and application, 336.

Choline deficiency, biological and chemical studies related to, 698.

Choline in poultry rations, Wash. 404.

Chondrodystrophy, hereditary, in fowl, [N.Y.] Cornell 47.

Chorizagrotis auxiliaris, *see* Cutworm, army.

Christmas tree plantation and livestock pasture, combining on cut-over lands, Mich. 804.

Chromatographic adsorption analysis, 627.

Chromosome(s)—

- and genes, structure and organization, 495.
- breakage and sterility in mice, 363.

Chromosome(s)—Continued.

counts in plants with small chromosomes, 358.

in plants, number, form, and behavior, [N.Y.]Cornell 53.

numbers in Hydrophyllaceae, 495.

somatic and homotypic, structure in, 31.

Chrysanthemum(s)—

blindness in, causes [N.Y.]Cornell 64.

breeding, Tenn. 371.

cuttings, root structure, effect of root media, Mass. 775.

diseases, 243.

fall blooming, effect of short days, 225.
greenhouse, colchicine-induced polyploids, 46.

morifolium, seedling, anatomical study, 30.

Verticillium disease in greenhouse, [N.Y.]Cornell 68.

Verticillium wilt control, Ohio 817.

Chufa, weevils affecting, 95.

Church, rural, relation to other rural organizations, 878.

Chytrids, parasitism among, 230.

Cicadellidae at Chatham, Va., check list and new records for State, 549.

Cicadula bimaculata, transmission of wallaby ear disease of corn by, 812.

Cider production, effect of corky apples, 20.

Cigarette beetle—

control, U.S.D.A. 88.

in tobacco warehouses, natural enemies of, 822.

Cinchona—

seedlings, sensitivity to light intensity, P.R. 668.

seeds, loss of viability in, P.R. 668.

Cineraria virus diseases, Wash. 378.

Cirphis unipuncta, see Armyworm.

Citric acid excretion, relation to thiamin deficiency, 315.

Citrin solutions, crude, from lemons, preparation and estimation, 482.

Citronella and lemon grass *Helminthosporium* spot, 533.

d,l-Citruiline, synthesis, from nonbiological precursors, 4.

Citrus—

breeding, Fla. 790.

brown rot, control in orchard and packing house, 81.

brown rot gummosis prevention, 817.

bud mite control, 403.

canker eradication, U.S.D.A. 66.

chlorosis, lime induced, relation to soil factors, 64.

cost of production and grove organization, Fla. 869.

culture, Fla. 799.

diseases, color handbook of, 542.

dry root rot associated with *Fusarium* spp., Ariz. 805.

fertilization, Ariz. 798.

fertilizer requirements, Fla. 799.

Citrus—Continued.

fruit(s)—see also *specifio kinds*.

diseases in storage, prevention, 529.

filtered, auto-oxidation, 140.

freezing preservation, 17.

melanose and stem-end rots, Fla. 800.

quality studies, effect of nutritional treatments, Fla. 799.

yields, "normal", development for yield insurance plan, 583.

gummosis and brown rot fungus, life activities and control, 81.

insects, studies, 391.

juices and pulps, preservation, Fla. 760.

juices, freezing preservation, 17.

leprosis control in Brazil, 542.

maturity studies, Fla. 760.

melanose control, 542.

mycoflora in Georgian S. S. R., 529.

nitrogenous fertilizers for, Fla. 799.

orchard soils, cultural and fertilizer practices, 224.

peroxidase, distribution and preparation, 490.

production and physiological studies, Fla. 799.

progeny and bud selection, Fla. 799.

psorosis, successful transmission by bark grafting, 387.

rust mite in Florida, U.S.D.A. 88.

rust mites, 554.

scab control, Fla. 806.

species, *Phomopsis* sp. on, 542.

stem-end rot, comparative behavior of *Diplodia* and *Phomopsis* as cause, 542.

thrips control, improvements in insecticides for, U.S.D.A. 88.

thrips, reactions to sugar in poisoned baits, 250.

tissues, hydrocyanic acid absorbed by, during fumigation, Calif. 674.

trees, moisture studies under, using tensiometers, 674.

trees, top regeneration, effect of severity of pruning, 521.

varieties, new and new combinations, 35.

variety tests, Fla. 799.

Cladis nitidula, scale predator, notes, P.R. 695.

Cladosporium humile, perfect stage of, cause of maple leaf spot, 389.

Clay(s)—

material, degree of sorption, effect of stage of decomposition of organic matter, Idaho 632.

minerals, identification in Iowa soils by thermal method, 632.

minerals, thermal method as quantitative measure of, 633.

nature of, determination, Wis. 483.

particles, studies, with electron microscope, 24.

Clematis varieties, hardiness, Mass. 800.

Click beetles, life histories and habits, 253.

Climate(s)—see also Meteorology.

and accelerated soil erosion in arid and semiarid Southwest, U.S.D.A. 764.
 climax, and conservation, 485.
 of California, Köppen classification, 766.
 relation to plant diseases, 527.

Climatic—

changes from timberline of Mount Washington, indications of, 631.
 history, post-Pleistocene, of Prince William Sound region, Alaska, 36.
 variability, index of, 631.

Climatological—

data, 22, 631, Ohio 482.
 data on forest plantation in Nebraska sandhills, 182.
 records of United States, development, 631.

Climatology of U. S., regional, hail as factor in, 766.

Clitocybe root rot of bananas and other plants, 542.

***Clostridium*—**

acidi-uridi n.sp. from soil, 349.
botulinum, type E, differential characters of strains, action of toxins, 720.
cylindrosporum n.sp. from soil, 349.
kluyveri concerned in formation of caproic acid from ethyl alcohol, 349.
 spp., growth in anaerobic media, 34.
thermoaceticum n.sp., fermentation of glucose by, new type, 776.

Clothes moth—

control, sodium fluosilicate v. sodium fluoride for, Ill. 546.
 evaluating protection of fabrics from, 825.

Clothes, work, for women, U.S.D.A. 897.

Clothing—

family expenditures for, U.S.D.A. 158.
 supplies for college students, Miss. 897.

Clover(s)—

adaptation of foreign and domestic varieties, [N.Y.]Cornell 53.
 crimson, fertility and pH levels for, S.C. 367.

fertilizer tests, Fla. 791.
 inoculation methods, Fla. 792.
 insects, N.Dak. 248.

Ladino—

and timothy mixture, methods for ensiling, Me. 264.
 effect on milk yield, 2.
 for Northeastern States, U.S.D.A. 795.
 place in New Jersey farming, N.J. 366.

Lappacea, production tests, Tenn. 367.
 leafhoppers, toxicities of bordeaux mixture, pyrethrum, and derris to, 828.

red—

and alfalfa mixtures, Ky. 792.
 and subterranean, seed, pathogenic fungi in, 682.
 better strains, N.J. 369.

Clover(s)—Continued.**red—continued.**

breeding, Ind. 659, Iowa 212, Ky. 702, Tenn. 367.

culture tests, N.J. 504.

cutting tests, Ill. 504.

developmental anatomy, 191.

medium and mammoth, effect of cutting at different stages, Iowa 212.

nurse crop experiment with, Iowa 212.

roots, depth and spread, relation to soil treatment, N.J. 366.

rotation studies, Va. 793.

seed setting, hybridization, and length of corolla tubes, Iowa 212.
 strains, place in New Jersey farming, N.J. 366.

variety tests, Ill. 504, Iowa 212, Ky. 792, N.J. 366, Pa. 504.

vernalization treatment and photo-periodic induction, 369.

root borer, biology and control, [N.Y.] Cornell 90.

seed germination, Iowa 213.

seed production experiments, 512, Idaho 659.

variety tests, Ariz. 791, Del. 212, Fla. 791, Ill. 504.

white—

fluctuation and distribution, 661.

germination and growth, effect of thiamin additions, N.J. 368.

mosaic, complex nature of, 73.

pastures, management and returns on, Mich. 264.

pseudo-self-compatibility and relation to cross-incompatibility in, 652.

red, and crimson, selection and improvement, Del. 212.

seed production, effect of clipping, Del. 212.

vernalization treatment and photo-periodic induction, 369.

Clover-seed caterpillar, notes, Del. 245.

Clubroot resistance, role of mustard oil in, Wis. 528.

Clypeothecium, taxonomic data, 487.

Coacervates in physical and biological systems, 809.

Cobalt—

deficiency in sheep, development, 716.

radioactive, metabolism studies, 747.

requirements of beef cattle, Fla. 833.

Coccidia infesting Rocky Mountain bighorn sheep in Wyoming, Wyo. 273.

Coccidioides immitis causing club formation in granulomatous suppurating processes in cattle, 718.

Coccidiosis—

among sage grouse and other wildlife, 719.

bovine, diagnosis, overlooked intestinal lesion of value in, 272.

Coccidiosis—Continued.

- control in chickens, Oreg. 859.
- effect of feeding concentrated physiological saline to chickens, 119.
- in calves, 272.
- in chickens, ineffectiveness of cow urine in control, 720.
- in chickens, sulfur compounds for prevention, 119.
- in silage-fed feeder lambs, experimental production, 422.
- prevention, flowers of sulfur and charcoal for, 275.

Coccinellid(s)—

- predator of white peach scale on papaya, P.R. 695.
- predatory on bamboo scales, collection in Trinidad and Brazil, 89.

Coccytrypes n.spp. and biology, 546.*Cochlonema*—

- bactrosporium longius* n.var., description, 530.
- curyblastum* n.sp., destructive to soil amoebae, 530.

Cock(s)—

- Brown Leghorn, hen-feathering in, 49.
- fertility cycles in, Mass. 789.

Cockerel(s)—

- and pullets, comparative growth response to protein supplements, Wash. 404.
- sperm production and testes size in, Tenn. 360.
- weights of reproductive organs and viscera, action of prolactin and oestrone on, 502.

Cockroach—

American—

- distribution of arsenic in body, 249.
- resistance to sodium arsenite and nicotine, factors affecting, 397.
- toxicity of hellebore to, 249.

control, Ind. 694.

- German, effectiveness of dust mixtures against, 827.

Cockroach plant—

- economic value, Ariz. 791.
- nomenclature, Ariz. 776.

Cocoa—

- and iron-fortified cocoa mixtures, availability of iron in, 709.
- and iron-fortified cocoa mixtures, nutritive value of iron in, Mass. 880.
- effect on coagulation of milk, Mass. 842.
- powders, bacteriology, Mass. 760.

Coconut—

- caterpillar, bethylid parasite of, 403.
- cream, rancidity, prevention, P.R.U. 165.
- seeds, viability after floating in sea, 353.

Codling moth—

- bionomics and control, Iowa 247.
- clean-up experiment, 395.

control—

- U.S.D.A. 87.
- and birds in Ozarks, 254.
- factors affecting, 254.

Codling moth—Continued.

control—continued.

- light mineral oils for, ovicidal value, 395.
- programs, N.Y.State 402.
- replacing lead arsenate in, Wash. 394.
- rotenone and other organic insecticides for, 829.
- scraping and banding results, 395.
- with insecticides, 395.
- with light trap, Wash. 428.
- cover sprays, 547.
- cover sprays, timing, 400.
- ease of control in different years, 395.
- flight and worm entries, 824.
- larvae attractants, 821.
- larvae, *Tenebroides corticallis* on, 247.
- larvae, toxicity of phenothiazine to, effect of bentonite and of hydrated lime, 821.
- larvae, toxicity of semicarbazones to, 253.
- menace, 551.
- on pears, control, 824.
- second-brood, spraying for control, 393.
- studies, Ind. 694, Mo. 85, N.Mex. 393.
- tolerance to toxic action of insecticides, Mo. 85.

Cod-liver oil—

- polyethenoid esters from, effect of vacuum distillation on absorption spectra, 167.
- rations v. irradiation from sun lamps, effect on egg production and hatchability, Mich. 262.
- stored in mixed feeds, effect of manganese sulfate on stability of vitamins in, 555.

Coclophora—

- inaequalis*, shipment to Louisiana, P.R. 695.

malivorella, see Pistol casebearer.*Coenurus* species, differentiation by hook measurement, 392.

Coffee—

- chaff as soil amendment, Mass. 800.
- Columnaris variety, productivity and growth, P.R. 668.
- disease in Angola, 81.
- farming, profitability, P.R.U. 284.
- Fusarium* root rot, P.R.U. 229.
- groves, hormiguilla in, poison for control, P.R.U. 248.
- leaf-miner, notes, P.R.U. 248.
- pruning, comparative studies, P.R.U. 465.
- research, P.R.U. 221.

Coleoptera

- associated with ironweed, 540.
- introduction and lists, 90.
- new, from Puerto Rico, P.R.U. 400.
- of Washington: Scolytoidea, 400.

Coleosporium hellanthei, nuclear phenomena involved at meiosis in, 807.

Coleus plants, yellow, transpiration rate, effects of inert dusts, 197.

Coliform—

bacteria, relation to bacterial plant pathogens, 228.

organisms and pasteurization, 107.

Collagen in animal tissues, determination, rapid method for, Iowa 256.

College—

men, basal metabolism of, Wyo. 880.

students, clothing supplies for, Miss. 897.

students, dietary habits, 592.

Colletotrichum—

falcatum, notes, 535.

falcatum, physiological studies, 70.

genus, studies, 70.

gloeosporioides growth in culture, *Actinomyces* inhibiting, 486.

lagenarium on honeydew melon, Colo. 238.

indemuthianum on beans, varietal susceptibility, 529.

sp. on corn, 234.

trichellum on stems of ivy, U.S.D.A. 805.

Colloidal complex and plant nutrition, adsorbed ions on, 772.

Colloids, soil, effect on plant growth, 25.

Collops bipunctatus, notes, 247.

Colon-typhoid-dysentery group, effect of sulfonamide derivatives, 564.

Color system—

permanganate-periodate, stability, 171.

two-component, colorimetric analysis, 171.

Colorado Station notes, 756.

Colostrum and milk, examination for *Brucella abortus*, 567.

Colts, growth and development, Iowa 257.

Combine(s)—

efficiency at various stubble heights, 862.

power take-off driven, horsepower requirements, 123.

small, studies, Mo. 120.

smaller, use, effect of field and crop conditions, Ill. 573.

Commodity Credit Corporation, laws and executive orders concerning, U.S.D.A. 437.

Community—

life in Iowa during World War I, Iowa 135.

local, and social control, 738.

organization, Ky. 877.

Riner, population turnover in, Va. 737.

Concrete—

coatings, acid-resistant, 121.

expansion through reaction between cement and aggregate, 121.

masonry wall construction, good practice in, 577.

mixes, design, proposed recommended practice, 121.

plastic flow in under load, effect of change in moisture content, 577.

reduction in amount of cement required in, Idaho 725.

reinforced, saving steel in, proposed emergency code, 577.

Condensers, reflux, support for, 761.

Conifer(s)—

bluestaining fungus inhabiting heartwood, 693.

diseases, new, in Gulf coast area, 245.

rabbits as hazard to plantations of, Mich. 245.

redwood in, seedlings for experimental study, 525.

seedling, damping-off, cause, 83.

squirrel damage to, 545.

Contothyrium psammae, notes, 72.

Connecticut [New Haven] Station—notes, 160, 466, 900.

report, 899.

Conotrachelus nenuphar, see Plum curculio.

Conservation—

and private enterprise, 582.

and society, 582.

objective or ideal, 583.

of natural resources in the Americas, 755.

public policy and action for, 582.

Constructional materials, nonmetallic, 726.

Cooking, utensils, metal, review, 464.

Cooperation, see Agricultural cooperation and Marketing, cooperative.

Cooperative(s)—

agricultural, case studies, Tenn. 294.

associations—

farmers', distribution of machinery by, U.S.D.A. 296.

farmers', milk distribution by, U.S.D.A. 295.

for wool marketing in Kentucky, Ky. 875.

in Michigan for marketing or processing fruits and vegetables, Mich. 874.

marketing eggs, Mich. 875.

canning of fruits and vegetables, U.S.D.A. 295.

effect of milk control programs, 582.

farmers', financial management analysis, Mich. 734.

farmers', personnel management in, U.S.D.A. 294.

horticultural, success in Puerto Rico, P.R.U. 440.

movement, Finnish-initiated consumers', in North Central States, 588.

since World War I, appraisal of changes, Okla. 130.

Cooperia oncophora in horses, 718.

Copper—

adsorption and fixation in sandy soils of central Florida, 190.

and iron, effect on hemoglobin regeneration, 455.

arsenite, new anopheline larvicide, 696.

blood, of ewes during pregnancy, 361.

compounds, reduction in fungicidal value by organic materials, 380.

deficiency of cattle, 568.

fungicides and insecticides, tests of compatibility of inert dust carriers for, Del. 227.

Copper—Continued.

- fungicides and substitutes, safety, N.J. 377.
- fungicides, "insoluble," fungicidal value and tenacity, relation to particle size, 380.
- fungicides, "insoluble," tests, Tenn. 378.
- fungicides, mechanism of action, 380.
- in blood of sheep and of cows, 115.
- in fungicidal sprays, substitutes for, 231.
- reduced by sugars, determination, 332.
- requirements of beef cattle, Fla. 833.
- salt, new in agriculture, use, 381.
- sprays on powdery mildews, stimulatory and toxic effects, 531.
- sprays, studies, Me. 228.
- sulfate drench, composition, effect of storage, 565.
- toxicity, effects of aluminum, 613.
- xanthates, fungicidal and phytocidal properties, 531.

Coralberry seeds, germination studies, 618.

Corn—

- and hog prices and expectations, Iowa 283.
- and oats, comparison as to production, labor, and use, Miss. 795.
- and sorghum in alternate rows, S.Dak. 504.
- and teosinte, cytogenetic study, Mo. 359.
- autotetraploid, fertility and vigor in effect of heterozygosis, 206.
- bacterial wilt—
 - of dent inbreds, 73.
 - resistance, genetic studies, Iowa 228.
- borer, European—
 - colonization of imported parasites of, 89.
 - control, Ind. 694.
 - damage, reduction by late planting Ohio 551.
 - insecticides for control, Mass. 820.
 - moth, egg laying by, height of corn as factor, 550.
 - parasite, reared on Mediterranean flour moth for colonulization, U.S.D.A. 254.
 - resistance of New Jersey corn hybrids and open-pollinated varieties to, N.J. 366.
 - strains of corn resistant to survival, U.S.D.A. 550.
 - studies, 393, Conn.[NewHaven] 822, Del. 245, U.S.D.A. 88.
 - susceptibility of corn strains to, relation to aphid infestation, 252.
- breeding, Conn.[New Haven] 791, Fla. 791, Idaho 659, Ind. 659, Ky. 792, Mo. 52, N.J. 366, [N.Y.]Cornell 53, P.R.U. 213, Pa. 504, S.Dak. 504, Tenn. 367.
- carotene in, factors affecting, Ill. 588.
- caryopsals of, origin of suberized semi-permeable membrane in, 205.

Corn—Continued.

- characteristics relating to industrial utilization, Iowa 165.
- chromosomes in, number, form, and behavior. [N.Y.]Cornell 53.
- cockle, feeding to poultry, effect, 276.
- composition and nutritive value, relation to soil type and fertilizer treatment, Ind. 659.
- cost of husking and cribbling with different corn pickers, Ill. 583.
- crop of 1941, ear rots in, U.S.D.A. 805.
- culture, methods and equipment, Iowa 277.
- culture tests, Fla. 792, S.Dak. 504, Tenn. 367, Wyo. 793.
- curing and storage, Iowa 277.
- cyanamide as source of N for, Ind. 659.
- dent, hybrid and open-pollinated varieties, composition, Ind. 659.
- dent, *Pythium* root rot, relative susceptibility of inbreds to, 683.
- development, interaction of water, growth, hormones, and food supplies in, Iowa 191.
- Diplodia zeae* dry rot, Iowa 228.
- disease(s)—
 - in Philippines, 234.
 - resistance in, measuring, Iowa 228.
 - survey, S.C. 378.
- drilled, production costs, 432.
- ear pests control, P.R. 695.
- ear rot fungi, prevalence and geographic distribution, U.S.D.A. 377.
- ears, mode of entrance of fungi into and symptoms, 383.
- earworm—
 - biology and control, U.S.D.A. 88.
 - control, Ky. 822.
 - control, mineral oil treatment, 829.
 - in sumac sorgho heads, effect of parasites and predators, 821.
 - studies, 393, Ind. 694, Mo. 85, P.R. 695, P.R.U. 394.
 - value of dusting, Ill. 545.
- farm storage, Iowa 277.
- fertilization in southern Illinois, 52.
- fertilization problems in use of ammonium sulfate, Ind. 659.
- fertilizer placement with, Ind. 659.
- fertilizer tests, Ind. 659, Miss. 660, Mo. 53, P.R.U. 213.
- field shelling of, 579.
- for fattening cattle, Mo. 99.
- for oil and protein content, breeding, Ill. 504.
- genetic studies, Conn.[New Haven] 791, Mo. 52.
- grains, carotenoid pigments and content, Ind. 616.
- ground, v. sorghum grain, ground, in dairy rations, S.Dak. 563.
- growing for high yields and low costs, N.J. 369.
- grown on high-lime soils, cation balance, relation to potassium deficiency, 668.

Corn—Continued.

- growth and yield, factors affecting, Iowa 182.
- growth, effect of soil temperature, Mass. 775.
- growth effect of translocations, 206.
- harvested in different ways, effect on gains of steers, Tenn. 404.
- high- and low-protein strains, development, S.Dak. 504.
- hybrid(s)—
 - and open-pollinated varieties, composition, Ind. 659.
 - and varieties, yield tests, Del. 212.
 - chemical studies, Ind. 616.
 - comparisons and production, Mass. 793.
 - development, compared with single crosses and inbreds, Iowa 191.

 v. urea, tobacco crop-producing capacity, Conn.[New Haven] 796.
 oil, crude, gossypol determination in, 176.
 treatment, Miss. 235, N.Mex. 366, 683.
 Coumarin compound from sweetclover as anti-blood-clotting factor, 1.
 Country, *see* Rural.
 Cover crops—
 effect of time of plowing under, Ill. 514.
 variety tests, Fla. 791.
 winter, comparison, Tenn. 367.
 winter, effect on percolation and nutrient losses, S.C. 342.
 Cow(s)—*see also* Cattle and Heifer(s).
 age, live weight, and milk-energy yield, correction, 265.
 artificial insemination, effect of diluters and storage on fecundity of semen, 657.
 artificial insemination in, Mo. 47.
 beef, distillers' corn dried grains v. cottonseed meal for, Ky. 834.
 concentrate mixture for, effect of quality of protein in, [N.Y.]Cornell 104.
 concentrate mixtures for, value of ground whole grains v. byproducts feeds in, [N.Y.]Cornell 104.
 copper in blood of, 115.
 dairy—
 accuracy of live weights on pasture, 265.
 alfalfa silage v. Atlas sorgo silage for, Ariz. 841.
 cost of keeping per year, N.J. 434.

Cow(s)—Continued.

dairy—continued.

effect of rest periods on subsequent milk production, Ill. 562.

relative availability of carotene in rations for, Ind. 704.

replacements in New York, marketing, [N.Y.]Cornell 130.

value of molasses- and phosphoric acid-alfalfa silages in rations, 410.

fed hegari fodder and cottonseed meal, relative carotene and vitamin A in blood, liver, and butterfat, N.Mex. 411.

feeding to control vitamin A in butter, 105.

in Iowa cow-testing association herds, persistency and inheritance of milk and fat production, Iowa 263.

lactating and dry, course of fasting energy production curves in, Mo. 103.

measurements and weights in Cornell dairy herd, [N.Y.]Cornell 104.

milk production, *see* Milk production.

milking, closed barns v. open sheds for, Wyo. 842.

milking, silage types for, S.Dak. 563.

new feeding standards for, Ill. 562.

normal, effect of sulfanilamide, Pa. 569.

sterile or difficultly bred, attempt to restore fertility in, [N.Y.]Cornell 846.

udders, *see* Udder.

Cowpea(s)—

ascorbic acid in, factors affecting, 351.

curculio studies, S.C. 393.

mineral composition under various conditions, S.C. 371.

variety tests, N.Mex. 366.

Cowpox studies, 853.

Crab apple, vitamin C in, 605.

Crab meal—

research, Mass. 761.

v. fish meal for poultry rations, Mass. 887.

Crambus toparius, *see* Cranberry girdler.

Cranberry(ies)—

bog(s)—

clearing for replanting, caution on use of arsenicals for, 520.

control of weeds and shrubs by chemicals, Mass. 793.

frost protection by wind machine, Mass. 800.

fungicides for, Wash. 378.

San Jose scale injury to, dormant sprays for, Wash. 394.

weeds, effect of flooding to kill root grubs, Mass. 793.

bordeaux pyrethrum spray for, time of application, 241.

breeding, Wash. 372.

disease control in wartime, 541.

false blossom-resistant strains, development, Mass. 800.

Cranberry(ies)—Continued.

false blossom virus in dormant vines, failure to inactivate by heat, 816.

fertilization, N.J. 371.

fruitworm control, Mass. 820.

girdler control, Mass. 820.

harvesting and handling, U.S.D.A. 224.

insects affecting, Mass. 820.

irrigation requirements, Wash. 372.

products research, Mass. 760.

root grub, notes, Mass. 820.

sanding experiment, 241.

syrup, vitamin C in, 605.

storage studies, Mass. 859.

tipworm studies, Wash. 394.

vine injury, relation to oxygen in winter flooding water, Mass. 800.

Crauc flies of George Reserve, Mich. 552.

Cream—

changes in demand in New York metropolitan area, [N.Y.]Cornell 129.

containing sodium chloride, danger in applying Babcock test to, Idaho 703.

farm, determining quality, criteria for, Ky. 842.

for buttermaking, quality, improvement, Iowa 264.

frozen, maintaining quality in, Pa. 563.

frozen, methods of storing, Fla. 842.

holding in buying station, effect on mold content and quality, 415.

market, bacteriological study, 107.

mold development in, laboratory studies, 414.

mold growth in, factors affecting, Ind. 415, 704.

pasteurized, effect of handling and aging, 104.

phosphatase value, effect of flash pasteurization and subsequent treatment, 415.

plants, losses in, relation to errors in Babcock test, 707.

prices paid for, in various large cities, Idaho 729.

quality control program of Boston Health Department, 104.

route organization and operation, Iowa 283.

salt-treated, testing, danger of hydrochloric acid gas poisoning, 337.

separating methods, relation to quality when marketed, Ind. 704.

Creamery(ies)—

Iowa, butterfat losses in, determination, Iowa 264.

license division report, Ind. 414.

water supplies, bacteria in, N.Dak. 707.

Oreontiaes femoralis on cotton, biology and control, Ariz. 819.

Crepis, systematics, cytogenetics, and evolution in, 487.

Cricket—

mole, control, U.S.D.A. 88.

mole, parasites in Trinidad, 97.

Cricket—Continued.

Mormon, new parasite of, 403.

Mormon, studies, U.S.D.A. 88.

southern mole, on cigar-type tobacco in South, U.S.D.A. 394.

Crime patterns in rural South Dakota, 738.

Crioceris asparagi, see Asparagus beetle.

Cronartium—

coleosporioides, notes, 390.

ribicola, see White pine blister rust.

Crop(s)—

boron requirements, 346.

boron toxicity to, Ariz. 805.

diseases in Venezuela, survey, 229.

fumigation with methyl bromide and HCN, Fla. 799.

growth and yield, factors affecting, Iowa 182.

harvesting costs with combines of different sizes and types, Ill. 583.

high in protein, silage production from, [N.Y.]Cornell 104.

improvement, [N.Y.]Cornell 33, 68.

in rotation, effects of fertilizers, manure, and green manure, Ariz. 791.

in rotation, fertilizer tests, Ind. 659.

nutritional needs, plants as indicators, tests, 196.

of Puerto Rico, nutrient requirements, P.R.U. 184.

on different soil types, potash requirements, [N.Y.]Cornell 23.

or cutworms, Utah 696.

pests, work in Philippines, 90.

plants, root development, factors affecting, Wis. 505.

plants, seed treatment, methods and materials, Miss. 382.

production, machine and hand methods in, U.S.D.A. 297.

production, value of organic matter, Idaho 632.

reports, U.S.D.A. 299, 444, 586.

residues, value in soil, S.Dak. 483.

response to lime, manure, and fertilizers on different soil types, Iowa 183.

response to magnesium on Alabama soils, 775.

response to potassium fertilization, Iowa 183.

rotations, see Rotation of crops.

seeds, treatment, Miss. 681.

threshing with small combine, Idaho 725.

wireworm injury and effect of crop rotation, 253.

yields and quality, effect of excessive liming, Ky. 769.

yields and weather, U.S.D.A. 20.

yields, effect of burning off weeds before plowing, Fla. 792.

yields on terraces, Wis. 433.

yields, regression of on weather, methods of computing, Iowa 766.

Cropland, abandoned, in Cedar Creek area, revegetation, Mo. 794.

Crotalaria rotation studies, Fla. 792.

Crown-gall organism, polysaccharide produced by, 681.

Crucifer club root control, mercurials for, Mass. 807.

Crucifer diseases in North Carolina, U.S.D.A. 66.

Cryolite, synthetic and natural, assimilation of fluorine by rats from, 143.

Cryptoxanthin in yellow corn, determination, 8.

Cucumber(s)—

beetle—

spotted, studies, 391, Mo. 85.

striped, studies, Me. 248, Mo. 85.

studies, Ind. 694.

breeding for disease resistance, [N.Y.] Cornell 57.

copper dusts for, Mass. 807.

culture, U.S.D.A. 515.

downy mildew—

dusting for, Fla. 806.

resistance, 386, 787.

resistance, breeding for, S.C. 371, 378.

resistant variety, development, P.R.U. 229.

fermentation, bloater formation in, 19.

fertilizers for, S.C. 371.

fresh and pickled, nutritive value, 18.

growth, effect of root temperatures, Mo. 57.

mosaic resistant variety, development, P.R.U. 229.

mosaic strains on tobacco in Ontario and Quebec, 687.

physiological processes in storage, effect of waxing, 447.

pickle fermentations, gaseous products of, 18.

pickle, fresh, manufacture, bacteriological study, 18, 19.

polyploids in, 787.

Puerto Rico No. 39, P.R.U. 373.

salted, quality, determination with pressure tester, 18.

salting, 18, 19.

seed treatment, Mass. 800, N.Y.State 222.

varieties, N.Mex. 371.

viruses 3 and 4, aromatic amino acids in, 384.

virus 4, preparation and properties, 385.

yield and quality, effects of climatological factors, 18.

Cucumis genus, polyploids in, 787.

Cucurbit—

diseases in North Carolina, U.S.D.A. 66.

ovary developing, rates of cell division in various parts, 650.

seed globulins, 744.

Cucurbita, nuclear size in, 31.

Culex pipiens, vectors of St. Louis encephalitis virus, 711.

Culture media—

aseptic handling, simple technic, 809.

preparation, manual of methods, 34.

Culture media—Continued.

sterile, and bacterial cultures, bactericidal substances from, 34.

Curculio control with insecticides, 305.

Curculionids affecting chufa, 95.

Ourinus sp., scale predator, notes, P.R. 695.

Currant(s)—

black, leaf midge, 402.

black, vitamin C in, 605.

cultivated red, production of sporidia of *Cronartium ribicola* on, 818.

insects, life history and control, Wash. 92.

tomato ring spot on, 691.

varieties, N.Mex. 371.

Currency depreciation, effects on prices, production, and foreign trade, [N.Y.]Cornell 876.

Cutworm(s)—

army, notes, U.S.D.A. 88.

army, outbreak in Utah, 247.

biology and control, [N.Y.]Cornell 90.

on cigar-type tobacco in South, U.S.D.A. 394.

or crops, Utah 696.

pale western, U.S.D.A. 88.

research, Ind. 604.

Cyclamen mite, studies, Ill. 546, U.S.D.A. 88.

Cylas formicarius elegantulus, see Sweet-potato weevil.

Cylindrocopturus eatoni on pine, biology, 253.

Cylindrosporium leaf spot on red raspberry, U.S.D.A. 805.

Cyllene robiniae, see Locust, black, borer.

Cyperus rotundus, response to five moisture levels, 782.

Cypress, Arizona, frost injury artificially induced in, 67.

Cyrtorhinus fulvus for control of taro leaf-hopper, 89.

Cystoercus tenuicollis in squirrels, 419.

Cystine—

added to casein diets, lactation-promoting properties, 592.

synthesis in vivo, 744.

Dahlia—

root storage and insect control, Ga. 64.

variety test, Ga. 64.

Dairy—

Association, Weber Central, economic analysis, Utah 733.

barn, concrete, temperature, humidity, and air movement in, Ind. 725.

cattle and dairy cows, see Cattle and Cow(s).

engineering, 728.

farm management—

and costs in Pennsylvania, Pa. 437.

in Champlain Valley and relation to price level, Vt. 871.

study, [N.Y.]Cornell 130.

farms—

economic importance of raising replacement stock, N.J. 410.

returns on, Wyo. 867.

Dairy—Continued.

feed prices and World War II, [N.Y.]Cornell 130.

herd(s)—

Holstein, improvement through continuous use of proved sires, Wash. 411.

improvement work, N.J. 360.

profits from, La. 290.

purebred, improvement through continuous use of proved sires, Tenn. 411.

Industry in United States, bibliography, U.S.D.A. 436.

marketing in Oklahoma, Okla. 730.

molds, relative gas requirements, Wash. 411.

production and consumption, defense program in regard to, 104.

products—

copper content, relation to quality of finished product, Ind. 704.

cost of production, reducing, Mo. 733.

desirable bacteria in, stimulating growth of, Pa. 563.

fluorescent bacteria in, 847.

gallon weights, calculation, 850.

in diet, place of, 104.

marketing, Ind. 730.

of Iowa, standardization, Iowa 264.

standard methods for examination, 106.

suitability for frozen-pack methods, Wash. 411.

volume hauled per mile, relation to cost of hauling, Ill. 584.

rations—

adequacy of calcium and phosphorus supply in, Fla. 842.

comparative value, Iowa 263.

research—

at Reading, progress in, 104.

in Scotland, 411.

Science Association, American, meeting, 612.

sires, see Bull(s) and Sires.

Dairying—see also Creamery(ies), Butter, Milk, etc.

in Mexico and Cuba, N.Y.State 842.

in southern New England, competitive position, U.S.D.A. 290.

principles, treatise, 841.

Damping-off control, seed and soil treatment for, La. 810.

Dandelion control, dichloroethyl ether test for, Ky. 702.

Darbya, inferior ovary, anatomy, 31.

Dark adaptation—

among roentgenologists, biophotometric measurements, 313.

measurement with adaptometer, 741.

of high school children at different income levels, 743.

- Dill pickles**, pasteurization, 2, 18 19.
- Dilophus febrilis*** larvae in lawns, methods for control, 552.
- Dinitrocresol** and other dual purpose winter washes, 396.
- Dinitro-o-cresol** as eradicator spray for fruits, U.S.D.A. 377.
- Dinoderus minutus***, biological studies and control, P.R. 695.
- Diphenylamines**, fungicidal properties, 681.
- Diphtheria**, avian, new treatment for, P.R.U. 858.
- Diplodia***—
 forms resembling *D. frumenti*, comparative study, Fla. 806.
frumenti, notes, 234.
natalensis and *Phomopsis citri* as cause of citrus disease, comparative behavior, 542.
 spp. on corn, physiological studies, 73.
zeae dry rot of corn, Iowa 228.
zeae, mode of entrance into corn ears, 383.
- Disease(s)**—
 deficiency, *see* Diet deficiency diseases and specific diseases.
 of animals, *see* Animal diseases and specific diseases.
 of plants, *see* Plant diseases and specific host plants.
 transmission by airplane, possible dangers, 93.
- Dissection**, fine needles for, 627.
- Distemper**—
 canine, in a zoological park, epizootic, 858.
 inclusions, improved diagnostic stain for, 858.
- Distillers' waste** as protein supplement for poultry, Wis. 555.
- Ditylenchus dipsaci***—
nematocides for, 78.
 notes, 389.
 on *Trifolium pratense*, U.S.D.A. 527.
- Dodder**—
 in Ispedeza, control, Kans. 217.
 on petunia, U.S.D.A. 805.
- Dog(s)**—
 blood building in, effects of cobalt and liver substance, 718.
 blood cytology, effect of hyperplastic endometritis on, 117.
 expression of different types, genetic and endocrine basis, 211.
 feeds, inspection and analysis, Ky. 100.
 flies, studies, U.S.D.A. 89.
 pantothenic acid deficiency studies in, 558.
Strongyloides, occurrence and diagnosis, 274.
 tick, American—
 experimental transmission of St. Louis encephalitis to white Swiss mice by, 567.
 parasite of, 553.
 rickettsial infections in, knowledge necessary for study, 90.
 tick, brown—
 transmission of Q fever by, 111.
 transmission of tick-bite fever by, 851.
 vitamin B₆ deficiency in, 147.
- Dove**—
 mourning, ecology and management, Iowa 245.
 western mourning, ecology and management, Iowa 245.
- Downy mildew** fungi spore dispersal, mechanism, 536.
- Draeculacephala portola***—
 notes, 93.
 vector of chlorotic streak of sugarcane, U.S.D.A. 88.
- Drainage**—
 and flood-control engineering, 575.
 as conservation practice, 576.
 control in northern Everglades, 429.
 ditches, open, maintaining by grazing, 861.
- Dress fabrics**, all-silk and all-rayon, physical properties, 754.
- Drinking utensils**, sanitary quality, methods for determining, Mass. 760.
- Drosophila***, genetics of, 363.
- Drosophila***, mutation in, 44.
- Drought**—
 effect on movement of soil nitrogen, Ga. 770.
 effects, persistence, N.J. 342.
 in Queensland during the 50-year period, 767.

Drug(s)—

effect on motility of bovine rumen, 853.
plants, native to Great Britain, 643.
plants of San Salvador, 194.

Duck(s)—

baby wood, paratyphoid in, 277.
diving, spring flight through Iowa, 86.
egg-laying, commercial significance, N.J. 360.
egg laying of, as enforced relaxation oscillation, 841.
feeding, wartime, 837.
pintail, *Hymenolepis mastigoproedicta* from, 419.
ruddy, nesting, in Iowa, 246.
studies, Iowa 245.
tarsometatarsus, relative growth, 790.
wild, food plants, value, propagation, and management, 86.

Dusts—

as supplement to sprays to meet labor shortage, N.Y. State 323.
settling rate and fractionation, apparatus for study, 68.
settling rates of diluents in, Conn [New Haven] 822.

Dutch in Michigan, religion and assimilation of, Mich. 301.

Earth, rammed, walls, experiments in use, S. Dak. 573.

Earthworms, North American, check list and bibliography, 86.

Earwig—

European, natural enemies of, U.S.D.A. 83.

ring-legged, life history and habits, 399.

Easter lily bulbs, storage and forcing performance, 64.

Eating and drinking utensils, cleansing, effectiveness of detergents and procedures for, Mass. 760.

Echinophaga—

gallinacea, see Sticktight flea.

myrmecobii, life history and artificial breeding, 96.

Echinocystis, nuclear size in, 31.

Echinodontium tinctorium brown stringy rot on western hemlock, 543

Echinoparyphium aconiatum from intestine of ruffed grouse, 86.

Ecology, including adaptation and origin, 485.

Economic conditions in Yakima Valley, Wash. 436.

Ectoparasite-host records from Sierran region of California, 248.

Egg(s)—

albumin, see Albumin, egg.
consumption deficiency in Puerto Rico, P.R.U. 284.

content of alimentary pastes, determination, 336.

cooling and holding on farm, mechanical refrigeration for, Ind. 725.

cooling on farm and at grading stations, U.S.D.A. 127.

cooperative marketing, survey, Mich. 875.

Egg(s)—Continued.

cost of production, Ariz. 869.

farmers, monthly yield standards, N.J. 360.

formation in various sections of oviduct, physiology of, Ill. 496.

frozen, preparation, storage, and use, 882.

frozen, suitability for cake baking, 883.

hatchability, factors affecting, Mo. 99.

hatchability, role of pantothenic acid in, [N.Y.] Cornell 99.

hen's, maturation, fertilization, and early cleavage in, 658.

incubated, value and methods of feeding to pigs, 101.

incubation of, changes in form of inositol during, 841.

infertile, early detection, [N.Y.] Cornell 47.

inspection service, Federal-State, Ind. 730.

market, cost of production, Md. 561.

marketing, cooperative, in Kansas, Kans. 295.

markets, retail, in Indiana, Ind. 730.

meats, liquid, during processing, detection of bacteria in, 882.

of one hen, feed purchasing power of, Mo. 99.

percentage fertility, relation to time of insemination, 658.

prices, effect of size and interior quality, Ohio 586.

processed in mineral oil, cooking properties, 882.

production—see also Hens, laying.

and hatchability, effect of alfalfa leaf meal and dried cereal grass, 840.

and hatchability, effect of ultraviolet light v. cod liver oil ration, Mich. 262.

best hatching season for, N.J. 403.

costs and returns and effect of hen mortality on, Ill. 584.

different kinds of housing for, Wyo. 834.

effect of feather mites on, Mo. 85.

effect of temperature and ventilation, Ind. 698.

electric light for, 108, 278.

energy efficiency, Mo. 99.

improving, effectiveness of progeny testing for, N.J. 860.

in poultry, relation to protein, Wyo. 834.

intensity, inheritance of, Mass. 788.

percentages of protein for, S. Dak. 554.

profit calculator, Ariz. 448.

quality—

and consumers' preferences, relation to egg-grading practices, Iowa 321.
preservation by farm refrigeration, 841.

Egg(s)—Continued.

quality—continued.

relation to grain varieties, S.Dak.
554.

record, individual, improved inexpensive,
211.

riboflavin deficiency in, effect on embry-
onic development, 700.

room, evaporative, cooler and humidifier
for, 278.

size—

and quality, biological efficiency of
protein fractions on, Iowa 257.

inheritance of, Mass. 789.

large and small, breeding for, Ariz.
788.

physiology of, 364.

storage, bibliography, U.S.D.A. 703.

technic for photographing early cleavage
stages, 627.

uniformly rich in vitamin D, production,
Iowa 256.

white, raw, toxicity, explanation of, 312.
yields calculation by commercial farmers,
N.J. 360.

yolk—

discoloration produced by cotton-
seed meal, nature of, 840.

fat during incubation, relation to
hen's ration, Ky. 834.

formation, physiology of, 50.

Eggplant—

Phomopsis blight and fruit rot, Fla. 806.
tip-over disease, perfect stage of fungus
causing, 538.

Eggshell quality, effect of minerals, vitamins,
and storage, Wash. 404.

Eggs *platycephalus*—

effective against bamboo scales, P.R. 695
shipment of adults to Haiti, P.R. 695.

Eimeria—

ah-sa-ta n.sp., description, Wyo. 273.

antilocaprae, new coccidium from Amer-
ican antelope, 418.

crandallis n.sp., description, Wyo. 273.

neoleporis n.sp. in cottontail and trans-
missible to tame rabbit, 566.

nieschulzi growth-promoting potency of
feeding stuffs, 270.

tenella infection in chickens, ineffective-
ness of cow urine in control, 720.

tenella infections, period of protection
afforded by sulfur, 418.

El Cerrito, typical Spanish-American com-
munity in New Mexico, U.S.D.A. 587.

Elaemosoma petulans n.sp., description, 403.

Elastic yarns, types, manufacture, 753.

Elastin in animal tissues, determination,
rapid method for, Iowa 256.

Elderberry, vitamin C in, 605.

Electric—

current on rural lines, increase in con-
sumption, Ill. 573.

fences, insulating supports for, types,
[N.Y.]Cornell 120.

Electric—Continued.

mixers and beaters for household use,
Ind. 754.

power, irrigation pumping with, 279.

Electrical equipment for farm, building, 578.

Electricity uses on Washington farms, 278.

Electrification—

farm, needs of, 278.

rural, rank in New Jersey, N.J. 428.

Elements, minor—

absorption and excretion by man, 748.

in soils, tests for need of, Ky. 769.

relation to nutrition, 491.

Elevator(s)—

centralized, radius of operation, Ill. 584.

farmers', of Iowa, business stability,
U.S.D.A. 296.

Elm(s)—

American, epidemic dying due to phloem
necrosis, U.S.D.A. 692.

aphid, woolly, predator on, 247.

bark beetle(s)—

control, toxic and repellent sprays
for, U.S.D.A. 832.

smaller European, feeding injuries,
reactivation of Dutch elm disease
fungus by, 833.

smaller European, technic for arti-
ficially feeding fungus spores and
other substances, 92.

trapped in chemically treated trees,
U.S.D.A. 88.

borer, technic for artificially feeding fun-
gus spores and other substances to, 92.

Chinese—

Chalaropsis root rot of, 389.

disease of, 245.

strength properties, 079.

disease, Dutch—

and insects, Mass. 820.

control program, relation to bark
beetle on apple trees, 550.

eradication, U.S.D.A. 66.

pathogenesis and control, Conn.
[New Haven] 805.

relation to *Scolytus sulcatus* and
apple trees, 389.

spread by *Scolytus multistriatus* and
control, Mass. 806.

studies, [N.Y.]Cornell, 67.

diseases, notes, Mass. 806.

insects in United States, annotated list,
U.S.D.A. 92.

leaf beetle, notes, Tenn. 393.

phloem necrosis disease, insect vectors,
U.S.D.A. 88.

scale, European, notes, Ill. 546.

Elsinoe—

hansfordii n.sp., description, 530.

new species from Brazil, 70.

parthenoclasti n.sp., description, 389.

Embryonic material, amyl acetate as clearing
agent for, 629.

Embryos of pregnant rats, effect of thyro-
tropic hormone on, 503.

Empoasca—

- fabae*, see Potato leafhopper.
- filamenta* control, Idaho 694.
- maligna*, see Apple leafhopper.

Encephalitis—

- human, and equine encephalomyelitis, 110.
- human, caused by equine type of virus in Minnesota, 274.
- in cattle, diseases causing, 568.
- in red fox in Ohio, 719.
- St. Louis—

- and human equine encephalomyelitis, 566.

- experimental transmission to white Swiss mice by American dog tick, 567.

- virus, experimental and natural in horses, 717.

- virus, transmission by *Culex pipiens*, 711.

- western equine and St. Louis types, epidemiological aspects, 117, 717.

Encephalomalacia in chicks, cause and prevention, [N.Y.]Cornell 99.**Encephalomyelitis—**

- avian, Mass. 858.

- canine, 425.

- equine—

- and human encephalitis, 110.

- cerebral resistance to, relation to neutralizing antibodies in cerebrospinal fluid, 717.

- experimental, significance of neutralizing antibody in, 566.

- in Massachusetts, 117.

- in United States in 1941, 857.

- studies, 117, 274.

- susceptibility of golden hamster to, 718.

- virus and antiserum, neutral mixtures, effect of dilution, 566.

- virus protein, effect of ultraviolet light, 424.

- western type in humans, 852.

- human equine, and St. Louis encephalitis, 566.

- sporadic bovine, 713, Tex. 854.

- transmission experiments from horses to guinea pigs, 419.

Endoconidiophora adiposa, decomposition of lignin fraction of sulfite waste liquor by, 85.**Endocrine—**

- glands, role in growth, reproduction, and lactation, 789.

- system and hormones, 498.

Engineering—

- agricultural—

- case for, 609.

- in national defense, 427.

- research in Great Britain, 756.

- biological, case for, 609.

- dairy, 728.

- in wartime agriculture, 572.

Engineering—Continued.

- laboratory instruction, unit-operations method, 445.

- Enoclerus aphegeus*, predator of mountain pine beetle, 95.

Enteritis—

- infectious catarrhal of turkeys, transmission and prevention, 426.

- nonspecific, of chickens, and fowl leucosis, radiant energy in study, Iowa 270.

- swine, sulfaguanidine in treatment, 423.

- Enterobius vermicularis* eggs exposed to household fumigants, survival, 419.

- Enterohepatitis, infectious, see Blackhead.

- Enterotoxemia of lambs, studies, 116.

Entomological—

- problems of Pacific area of interest to medical entomologists, 89.

- service, insecticidal problems, 545.

- stations in Ecuador, gazetteer, 392.

- survey of Micronesian Islands under Japanese mandate, 89.

- Entomology—see also Insect(s).

- Philippine, survey, 89.

- Entyloma* n.sp., description, 381.

Enzymes—

- and fermentation, chemistry of, and Liebig, 616.

- and trace substances, 471.

- Enzymology and related subjects, advances in, 471.

- Eosinates, their spectra and staining capacity, 629.

- Eperythrozoon wenyon* bodies in blood of cattle, 272.

- Ephedra sinica*, cultural and assay tests, S.Dak. 504.

Ephestia—

- cautella*, see Almond moth.

- clutella*, see Tobacco moth.

- kuehniella*, see Flour moth, Mediterranean.

Epiblema—

- otiosana* parasite, Va. 824.

- strenuana* parasite, Va. 824.

- Epilachna varivestris*, see Bean beetle, Mexican.

- Epiphytes, parasites, and geophytes, production of alkaloids and cyanogenetic and organic sulfur compounds, 68.

- Epitritomerus hystrix* on timothy, 833.

Epitritia—

- cucumeris*, see Potato flea beetle.

- parvula*, see Tobacco flea beetle.

- subcrinita*, see Potato flea beetle, western.

- Equidae, crystalloids in hypophysis, 655.

- Equines, nutritional diseases, 274.

- Ergot, artificial production, 232.

Eriophyes—

- essigi*, studies, U.S.D.A., 88.

- sheldoni* control, 403.

Eriosoma—

- americanum*, see Elm aphid, woolly.

- lanigerum*, see Apple aphid, woolly.

Bristalis tenax genital myiasis in a cow, 421.
 Erosion, *see* Soil erosion.
 Erwineae, serological studies, 70.
Ervinia—
 aroidae, causing poppy bacterial soft rot, 83.
 carotovora, fermentative ability, 71.
 phytophthora, notes, 236.
Erysipelothea rhusiopathiae growth requirements, 711.
Erysiphe—
 cichoracearum, resistance of phlox to, 388.
 polygona, conidia, development, structure, and germination at low humidity, 70.
 Erythrocytes—
 hen, preparation of living nuclei from, 720.
 of cattle, additional antigens in, 854.
Erythroneura, *see* Grape leafhopper.
Escherichia—
 acidi lactici, pathogenicity for turkeys and response to agglutination test for pullorum disease, 723.
 and *Aerobacter*, tests for differentiation, [N.Y.]Cornell 33.
 coli—
 aging without reproduction and viability of young cells, 776.
 bacteriophages active against, morphology and particle diameter, 644.
 lethal effect of drier rolls on, 348.
 use in determination of vitamin C, 623.
 Ethyl—
 carbamate, effect on respiration of yeast, 201.
 methacrylate as medium for mounting embryos and small adults, 628.
Euborellia annulipes, *see* Earwig, ring-legged.
Euetheola rugiceps, *see* Sugarcane beetle.
Euphorbia—
 chromosome number relationships in genus, 31.
 spp., response to photoperiod and temperature, effect of light intensity, 225.
Eutettix tenellus, *see* Beet leafhopper.
Euzesta stigmatias, notes, P.R. 695, P.R.U. 394.
 Evaporation—
 from land and water surfaces, measurement, U.S.D.A. 340.
 measure of, 632.
 micro-, apparatus for, 331.
 Evergreen(s)—
 hardiness, factors affecting, Mass. 800.
 seedlings, inoculation with mycorrhizal fungi, Wis. 524.
 Evolution and genetics in light of religion, 206.
 Ewe(s)—*see also* Sheep.
 bred first as lambs v. ewes bred first as yearlings, performance, 210.
 breeding, deficiencies of nonleguminous roughages for, 98.

Ewe(s)—Continued.
 breeding, winter rations for, Ind. 698.
 gummer, fattening, 97.
 in lambing camp, rations for, Wash. 835.
 lambing, effect of gonadotropic hormones, Tenn. 350.
 native mountain and northwestern, comparison, Tenn. 360.
 ovarian changes during oestrus and ovulation, Mo. 47.
 pregnant—
 blood copper of, 361.
 comparative rations for, S.Dak. 554.
 cottonseed meal in ration of, 97.
 rye v. bluegrass and alfalfa hay v. red clover hay for, Ky. 834.
 treatment of with phenothiazine, 570.
 range, selection, importance of body weight in, 97.
 rations for, Wash. 404.
 reproduction of, effect of nutrition, Okla. 700.
Ezochomus foudanti, new predator of bamboo scale, P.R. 695.
 Experiment station(s)—
 data, statistical investigations, Iowa 213.
 in 1941, editorial, 613.
 organization list, U.S.D.A. 880.
 report, 755.
 seed shipments to Russia, 756.
 significant findings of, editorial, 1, 161.
 Extension work, cooperative, relation to national defense and security, U.S.D.A. 136.
 Fabric(s)—*see also* Textile.
 antcrease finish for, discussion, 463.
 cotton, linen, and rayon-mixed, physical properties, 310.
 mixed, analysis, method adapted for, 463.
 quality, judging, U.S.D.A. 608.
 wool and part wool, effect of wear on, S.Dak. 608.
Fabriciella n.spp., descriptions, 553.
 Factor Z_1 —
 and hypoxanthine, identity, 645.
 as growth substance of *Phycomyces*, 194.
 Family(ies)—*see also* Farm family(ies).
 assets and liabilities of, changes in, U.S.D.A. 158.
 classification summary, Nev. 280.
 expenditures for—
 clothing, U.S.D.A. 158.
 education, reading, recreation, and tobacco, U.S.D.A. 897.
 housing and household operation, U.S.D.A. 159.
 personal care, gifts, selected taxes, etc., U.S.D.A. 159.
 farm and village of Vermont, incomes and expenditures, 164.
 finance in wartime, home economists' responsibilities, 754.
 food consumption and dietary levels, U.S.D.A. 136.
 German worker, food consumption, U.S.D.A. 284, 307.

Family(ies)—Continued.

- income and expenditures, U.S.D.A. 321, 608.
- living cost on farms, Mo. 129.

sulfuring, burning of sulfurs used in, Calif. 339.

tests, Ariz. 799.

thinning, effects, Miss. 671.

tissue, frozen-stored, inactivation of browning system in, 645.

Fruit(s)—Continued.**tree(s)—**

black cancer, control with naphtha byproducts, 229.

budded, crown gall on, 386.

effect of blizzard of 1940 in Iowa, 767.

in irrigated regions, control of orchard mites on, Wash. 394.

insects studies, 394.

leaf roller in Kickapoo apple area, Wis. 546.

low-producing, effect of manure on yield, [N.Y.]Cornell 61.

mature, framework grafting, 670.

nutritional conditions, relation to biennial bearing, growth, and yield, [N.Y.]Cornell 61.

pome and stone, damage in Missouri from severe freeze, 707.

rough-bark diseases, transmissible, 387.

stocks in Iowa nurseries, diseases, Iowa 228.

trials and other introductory plantings, Fla. 799.

winter injury, factors affecting, Wash. 372.

tropical, studies, 63.

varieties for Ohio, recommended and new, descriptions, Ohio 516.

varieties, selecting, Mo. 60.

varieties, tree characters, Mass. 800.

variety tests, Ky. 800, Mass. 800, Wash. 372, Wyo. 801.

Fruitlet(s)—

in Argentina, 402.

Mediterranean, U.S.D.A. 88.

Mexican, U.S.D.A. 88.

West Indian, adult populations in citrus plantings in Puerto Rico, P.R. 96.

Fruitworm(s)—

control, Ky. 822.

effect of cryolite on, Miss. 256.

in blueberries, control, N.J. 391.

oriental, studies, Ind. 694.

rotenone sprays for control, Wash. 394.

Fuel wood used in United States, U.S.D.A. 227.

Fumago sacchari, notes, 535.

Fumigants—

greenhouse, Mass. 820.

new methods of applying, U.S.D.A. 5.

Fungi(us)—

and bacteria, antibiosis between, studies, 486.

collected from crop plants and diseases caused by them in Georgian S. S. R., 529.

conjugate nuclear division in, 494.

cultures, mounting for preservation in herbarium, 529.

entomogenous, 67.

filamentous, vitamin deficiencies, 644.

genetics, papers on, 208.

Fungi(us)—Continued.

growth in culture, actinomycetes inhibiting, 486.

hyphae, composition, 349.

micro culture slide for, 331.

migration of nuclei in an electric field, 493.

of Mount Shasta, host index additions, U.S.D.A. 680.

of Nevada, U.S.D.A. 527.

parasitic, of Wisconsin, 807.

parasitic on cereals, U.S.D.A. 680.

parasitic, on cereals and grasses, revised check list, U.S.D.A. 70.

predaceous, 68.

seed-borne, on cereals in Canada, 532.

spore germination in presence of copper and sulfur, effect of temperature, 380.

spores, air-borne, 193.

spores, primary dispersal and isolation of, 776.

taxonomy, importance of variation in, 35.

wood-destroying, U.S.D.A. 680.

Fungicidal action, mechanism, 380.

Fungicidal substances, new, 381.

Fungicide(s)—*see also* Spray(s) and specific kinds.

airplanes for application on cranberry bogs, N.J. 391.

and insecticides, analyses, Mo. 221.

copper, *see* Copper.

evaluation, dosage-response curve in, role of, Conn.[New Haven] 230.

ingredients commonly used in, specifications, Ohio 178.

new, 531.

nonlinear dosage-response curves, hypothesis account for, 67.

shortage, suggestions for meeting, Conn. [New Haven] 805.

studies, 531, Miss. 382.

use in wartime, 810.

Fur—

animals of North America, bibliography, 391.

fibers, types, 558.

wild, production and use on agricultural land, U.S.D.A. 86.

Furniture carpet beetle. Biology, [N.Y.]Cornell, 94.

Fusarium—

batatas vanillae root rot, blighting factor in vanilla production, P.R. 679.

bulbigenum lycopersici on Pan America tomato, 239.

culmorum, colonization on buried wheat straw, 382.

from subterranean clover seed, 683.

moniliforme, mode of entrance into corn ears, 383.

oxysporum cubense in soil, effect of chemicals, 70.

solani martii on American holly, N.J. 378.

species concept in, 70.

Fusarium—Continued.

- sp., lysis in, destructive changes of protoplasm, 87.
 spp. associated with wheat root rot, pathogenicity, 687.
 spp. from cotton, tobacco, and other plants subject to wilt, cross inoculations, 807.
 taxonomic characters, effect of light, 194.
 wilt of China aster, Ind. 679.
 wilt of cotton, 234.
 wilt of potatoes, extensive occurrence, Idaho 679.
 wilt of watermelon, studies and control, Fla. 808.
 wilt organisms, cross-inoculations, S.C. 378.
Fusiformis nodosus n.sp. cause of sheep foot rot, 278.
Galerucella xanthomelaena, see Elm leaf beetle.
 Gall midge injury to red pine, 245.
Galleria mellonella, see Wax moth.
 Gallium, boundary tension, 165.
 Game, production and use on agricultural land, U.S.D.A. 86.
Ganoderma oregonense white spongy rot on western hemlock, 543.
 Garbage types, composition, digestibility, and nutritive value, 406.
 Gardenia—
 bud abscission in, Wash. 372.
 chlorosis, effect of vitamin B, at different soil temperatures, Mass. 807.
 nutrient and soil reaction needs, Ill. 523.
 Phomopsis stem canker, Mass. 807.
 Gardens—
 for food, health, and victory, Miss. 58.
 home vegetable, N.J. 669.
 irrigation experiments, Wyo. 801.
 spray machinery for, Miss. 863.
 Victory, Iowa 221, U.S.D.A. 58, Utah 221.
 Victory, insecticides for, S.Dak. 695.
 Garlic culture in North, Ohio 515.
 Gases, acid, in smoke, localized injury to plant organs from, 230.
 Gastric—
 juice secretion in deficient hydrochloric acid production, effect of vitamin A, 145.
 ulcers in rat, dietary factors related to, Iowa 308.
 Gastroenteritis, verminous, in calves, 272.
 Geese—
 feeding, wartime, 837.
 wild, food plants, value, propagation, and management, 86.
 young, feeding of cut grass to, 841.
 Genes and chromosomes, structure and organization, 495.
 Genetical Congress, International, proceedings, 43.
 Genetics—
 and evolution in light of religion, 206.
 and the origin of species, 43.
 in U.S.S.R., 206.
 new paths in, 786.

- Geocoris atricolor* feeding on pea aphids, 398.
 Geophytes, epiphytes, and parasites, production of alkaloids and cyanogenetic and organic sulfur compounds, 68.
 Geranium cutting(s)—
 root structure, effect of root media, Mass. 775.
 rot, 388.
Gibberella—
 fujikuroi, internal grain infection of corn by, 74.
 zeae, mode of entrance into corn ears, 383.
Gigantobitharzia gyrauli, life cycle, 86.
 Gingivitis treatment with ascorbic acid, 154.
 Girls, freshman, of Maine University, nutritional status, Me. 302.
 Gizzard—
 erosion in growing chickens, 840.
 lesions in day-old chicks, 561.
 Gladiolus—
 blight or rust, Fla. 709.
 chromosome number and hybridization in, 46.
 cormlet, origin and development, 786.
 culture, new diseases threatening, 82.
 Fusarium yellows control, 818.
 Fusarium yellows, varietal resistance, 692.
 thrips control, Ind. 694.
 thrips on corms, single treatment for destruction, 548.
 thrips, studies, Fla. 822, U.S.D.A. 88.
 Glass(es)—
 beverage, sanitization of, 888.
 container research, Mass. 761.
 drinking, of restaurants, bactericidal effect of ultraviolet rays on microorganisms, 305.
 Globulin(s)—
 of cucurbit seeds, 744.
 of watermelon seed, protein nutritional studies, Conn.[New Haven] 760.
Glomerella oingulata, inheritance of plus and minus characters, 80.
 Glucose—
 dissimilation by *Ochaetomium funicola*, 491.
 fermentation, new type, by *Clostridium thermoaceticum* n.sp., 776.
 ingestion, effect on blood pyruvic acid, 603.
 Glycerol determination, 176.
 Glycerol-water mixtures, entomological work with, maintenance of high atmospheric humidities for, 821.
 Glycine requirement of chicks, 838.
 Glycogen—
 formation in liver and muscle from glucose and fructose after extreme muscular exhaustion, 808.
 in oysters, determination, 336.
 of tissue, depletion during fasting and fatigue, and partial recovery without food, 808.
Glypta reftscutellaris, notes, Va. 824.

Gnat, Clear Lake, studies, U.S.D.A. 89.

Gnortimoschema gudmannella, studies, P.R.U. 248.

Goat(s)—

abnormal sex anatomy, 51.

and cow milk secretion, effect of fasting and refeeding, Mo. 103.

buck, quality of semen produced when does are not in heat, N.J. 360.

dairy, breeding, N.Mex. 411.

dairy, management, N.J. 706.

fed hagarl fodder and cottonseed meal, relative carotene and vitamin A in blood, liver, and butterfat, N.Mex. 411.

milk, bacterial content, 847.

milk, blood, and tissues, ascorbic acid in, N.C. 706.

new feeding standards for, Ill. 562.

nicotinic acid and manganese requirements, [N.Y.]Cornell 99.

poisoning from cloak fern, Tex. 565.

production, lawn clipping silage for, N.J., 408.

worm-free, effect of phenothiazine on weight, 423.

Gold absorption and excretion by man, 748.

Gonadotropic—

antisera, fowl and mammalian, specificity, 790.

antiserum, effect on postnatal development of male rat, 655.

hormone activity, effect of ascorbic acid, 362.

hormone, chorionic, preparation, new method, 780.

hormone from pregnant mare serum concentrating, Mo. 47.

Gonadotropin—

chorionic, response of gonads of testosterone-treated animals to, 51.

chorionic, response of uterine weight to, 655.

in pregnant mare serum and horse pituitary gland, comparison, 50.

Gooseberry—

breeding, Ill. 516.

insects, life history and control, Wash. 92.

varieties, N.Mex. 371.

Gossyparia spuria, see Elm scale, European.

Gossypium—

asynaptic plants and polyploids, 206.

chromosomes, 44.

species hybrids, haploids, and induced polyploids, meiotic chromosome behavior in, 208.

Gossypol in crude cottonseed oil, determination, 176.

Governmental costs and taxes in rural New York, [N.Y.]Cornell 130.

Gracilaria negundella, notes, 247.

Grain(s)—see also Cereal(s) and Oat(s), Rye, Wheat, etc.

and hay in mixed ration, digestibility, 257.

Grain(s)—Continued.

beetle, saw-toothed, in stored raisins, U.S.D.A. 88.

bins, ventilated, performance of cows for, 864.

conversion of weights of mechanical separations into percentages, U.S.D.A. 214.

crops, composition, effects of soil type and fertilizer treatments, 639.

crops for pigs, substitution of hay and pasture crops, Iowa 283.

dehydration, development of portable driers for, Ind. 725.

diseases, in California, U.S.D.A. 527.

diseases in Oklahoma, U.S.D.A. 527.

diseases, reports, U.S.D.A. 680.

drier, portable, 163.

feeding methods to layers, Fla. 833.

fermenting, with yeast for swine, Ill. 554.

fineness of grinding, effect on utilization by dairy cattle, S.Dak. 563.

germination, effect of storage in contact with seed-pickling dusts, 811.

insects, N.Dak. 248.

merchandising practices, Iowa 284.

moisture content increased by snow, N.Dak. 126.

price-guaranteeing policy of Argentina, evolution, U.S.D.A. 435.

producing, costs and practices in, Ind. 729.

riboflavin content and distribution in products of wheat milling, 750.

seed, cleaning and treating, annual necessity, N.Y.State 323.

shipments from points on Illinois River, Ill. 584.

small, diseases in North Carolina, U.S.D.A. 66.

storage, engineering phases, 580.

stored, insects—

control, N.Dak. 248, U.S.D.A. 88.

emergency research, Iowa 247.

killing by drying, Ill. 573.

stored, pest control, Mo. 393.

stored, protection, insecticidal value of dusts for, 395.

weeds in, control by chemical sprays, Wis. 505.

Gram foot rot, cause, 232.

Gram types, resistance to blight disease, determination, 232.

Gramicidin—

and Penicillin, comparative bacteriostatic activity, 33.

studies, 852.

Gramineae, western, leaf spot fungi on, 72.

Granuloma, coccidioidal, in cattle, associated with actinomycetoidlike clubs, 713.

Grape(s)—

berry moth, insecticides for, U.S.D.A. 88.

berry moth, spraying for control, Mich. 824.

cane girdler, biology and control, Mass. 820.

Grape(s)—Continued.

- cluster thinning, Ill. 516.
- Concord, chlorosis of, effect of root on, 542.
- Concord, substitutes for, Okla. 674.
- Concord, uneven ripening, Okla. 673.
- culture, P.R.U. 221.
- effect of modification of storage atmosphere, Iowa 220.
- fruit rots, Fla. 806.
- juice fermentation, formic acid formation in, 181.
- leafhopper—
 - new sprays for control, Ill. 546.
 - notes, Ind. 694.
 - spraying for control, Mich. 824.
- maturity, relation to yield, composition, and quality of raisins, Calif. 339.
- mold control in by sulfur dioxide, 816.
- muscadine varieties, ascorbic acid in, 895.
- nutrition, Mo. 57.
- oxidase activity, effect of pretreatment and subsequent drying, Calif. 339.
- plume moth, biology and control, Mass. 820.
- production, effect of boron on, S.C. 371.
- seedlings, growth, S.C. 371.
- seeds, muscadine, germination, S.C. 371.
- sultana, fertilizer experiments, 521.
- varieties, N.Mex. 371.

Grapefruit—

- boron toxicity to, Ariz. 805.
- fertilization, P.R.U. 221.
- juice, peel oil determination in, 377.
- quality and yield, factors affecting, Ariz. 798.
- quality, in commercial groves of Salt River Valley, Arizona, 521.
- rinds, hard spots or gum pockets in, control, Fla. 806.
- trees, nitrogen uptake by, Ariz. 798.

Grapevines, pruning, N.J. 370.

Graphium, pyridoxine as growth factor for, 83.

Grapholita—

- molesta*, see Fruit moth, oriental.
- packardii*, see Cherry fruitworm.

Grass(es)—see also Grassland(s), Lawns, Meadows, Pasture(s), etc.

- alpine, carbohydrate metabolism in, relation to adaptation problems, 37.
- and alfalfa combinations, Ky. 792.
- and alfalfa mixture on irrigated land, value, Colo. 214.
- and legumes grown in associations, interrelations, Ind. 659.
- aphid host records, 548.
- best suited to aviation landing fields, N.J. 366.
- British, diseases, 810.
- caterpillar, subterranean, chemical control, 551.
- composition and adaptations, Ill. 504.
- creeping bent, brown patch and dollar spot of, thiram disulfide for, N.J. 810.
- culture tests, Idaho 659, S.Dak. 504.
- diseases, U.S.D.A. 805.

Grass(es)—Continued.

- downy mildew of, 236.
- establishment in permanent pasture without plowing, N.J. 366.
- farming for improving depleted soils, Ky. 507.
- farming, studies, Mo. 213.
- fertilizer tests, Idaho, 659.
- for partially shaded areas, N.J. 366.
- forage—
 - and pasture, improvement, Fla. 792.
 - breeding, Wash. 367.
 - diseases, Wash. 378.
 - improvement, greenhouse germination and propagation method, 214.
 - on mountains, growth and carbohydrates in, effect of clipping and grazing, U.S.D.A. 505.
 - production, P.R.U. 213.
 - variety tests, Fla. 791, Idaho 659, S.Dak. 504, Wyo. 793.
- germination and growth, effect of thiamin additions, N.J. 368.
- grass associations, and legumes for pastures, [N.Y.] Cornell 53.
- grazing value on cut-over, dry Norfolk sand areas, Fla. 792.
- hybrids, inheritance of disease resistance, Wash. 367.
- improved, introduction into established sod, N.J. 366.
- in mixtures, tests, Ky. 792.
- mixtures for feed, carotene in, 257.
- native, reestablishing in Kansas, 792.
- new, from Venezuela, 777.
- nurse crops for, Ky. 792.
- of Montana, seasonal changes in lignin and cellulose content, 99.
- of Wisconsin, *Muhlenbergia* and *Sporobolus*, 36.
- parasitic fungi on, U.S.D.A. 680.
- pasture, breeding, Tenn. 367.
- pasture, promising, palatability, Iowa 213.
- range—
 - behavior and composition after burning, Fla. 792.
 - composition, N.Mex. 327.
 - growth and development in, 353.
 - tests, Wyo. 793.
- seed germination, 512, Iowa 213.
- seed, Michels', unsatisfactory for fattening hogs, Idaho 697.
- seed production experiments, Idaho 659.
- seed samples used in soil conservation, weed impurities in, 32.
- seed, sterilization technic, 810.
- seedlings on burned-over land, Idaho 659.
- seedling—
 - development physiology, 784.
 - emergence studies, 31.
 - establishment and productivity, 487.
- short, methods of quadratting, comparison, 505.
- silage, see Silage.
- snow mold of, cause, Pa. 528.

Grass(es)—Continued.

- sod-forming, fertilizers for, N.J. 366.
- southern, germinating seeds of, 512.
- stands, natural, effects of burning on maintenance, Fla. 792.
- Sudan and Bahia, growth, relation to development and deterioration of roots, Fla. 791.
- turf, response to fertilizers, Pa. 504.
- variety tests, Fla. 791, Ill. 504, Iowa 212, Pa. 504, Tenn. 367, Wash. 367.

Grasshopper(s)—

- control by tillage, N.Dak. 248.
- control, evaluation of baits in, U.S.D.A. 249.
- control, tillage methods as aid, N.Dak. 695, S.Dak. 546.
- control, use of mechanical bait spreaders for, 90.
- eastern lubber, life history, food preferences, distribution, and control, Fla. 822.
- immature, soybeans as host, Ill. 545.
- nonmigratory, biology, ecology, and control, Iowa 247.
- of Arizona, Ariz. 827.
- problems associated with strip cropping, 547.
- range, Wyo. 822.
- rearing under laboratory conditions, 828.
- research, S.Dak. 546.
- studies, U.S.D.A. 88.

Grassland(s)—*see also* Grass(es), Lawns, Meadows, and Pasture(s).

- insects, Conn.[New Haven] 822.
- maintenance in Vermont, Vt. 660.
- overgrazed and normal, insect distribution and seasonal succession in, 248.
- permanent fertility of, Pa. 482.
- plowing up, and wireworms, 253.

Grazing—*see also* Range(s).

- studies on northern Great Plains, N.Dak. 699.

Grease removal from sewage, acceleration, N.J. 428.

Grebes in British Columbia, 391.

Green manure—

- crops, date-of-seeding test, Ariz. 791.
- crops, variety tests, Ariz. 791.
- fertilizer tests, S.C. 367.

Greenhouse, all-electric, 278, Wash. 428.

Ground-nut seed, mycoflora of, 529.

Grouse—

- eastern ruffed, seasonal food preference trends, 545.
- ruffed, new parasite records from, 86.
- sage, coccidiosis in, 719.
- sage, insect food, 247.

Growth—

- initiation, effect of pH concentration, 196.

substance(s)—*see also* Plant growth substances.

- in plant propagation, nature and use, Colo. 801.

Growth—Continued.

substance(s)—continued.

- qualitative differences in capacity to induce formative effects, 32.
- synthetically produced, 39.

Grubs, white, *see* White grub(s).*Gryllotalpa hexadactyla*, *see* Cricket, northern mole.Guanine as growth substance for *Phycomyces*, 194.

Guava(s)—

- culture, P.R.U. 221.
- culture and industrial possibilities, P.R.U. 465.

Guinea pig(s)—

- assay of oestrone in, 51.
- embryos, death of, on diets low in vitamin E, 896.
- hereditary predisposition to sensitization, 497.
- reproductive organs, effect of diethylstilboestrol, 655.

Gymnandrosoma n.sp. in Dominica, 551.

Gypsy moth—

- as apple pest, Me. 248.
- control, Mass. 820, U.S.D.A. 88.
- in Pennsylvania, 547.
- notes, Conn.[New Haven] 822.
- project of Bureau of Entomology and Plant Quarantine, 95.
- threat of westward spread, 829.

Haemaphysalis humerosa—

- isolation of strains of *Rickettsia burneti* from, 111.

- transmission of Q fever by, 111.

Haemonchus contortus—*see also* Stomach worm.

- spermatogenesis and oogenesis in, 713.

Hail as factor in regional climatology of U. S., 766.

Hail in high and low latitudes, 631.

Hair, human, lanthionine isolation from, 166.

Hall's scale in California, U.S.D.A. 88.

Ham(s)—

- cured, distribution of salt and water in.
- improved method for determining, 259.
- farm-cured, salt absorption in, hastening, Pa. 836.

Hambletonia pseudococcinea, parasite of pineapple mealybug, P.R. 695.

Hamster—

- golden, susceptibility to equine encephalomyelitis, 718.
- nutritional requirements, 698.
- vitamin E and muscle degeneration in, 698.

Hanseniaspora causing date spoilage, 523.*Hapalia machaeralis*, biology, 395.*Haplothrips subtilissimus*, notes, 397.

Hawaii University notes, 610.

Hawthorns, Florida, ecologic notes, 487.

Hay—*see also specific kinds*

- and grains in mixed ration, digestibility, 257.
- and pasture management system v. pasturing alone, Mass. 793.

Hay—Continued.

- and silage, feeding value, Vt. 563.
 barn-dried, studies, 126.
 barn-dried v. field-dried, feeding value,
 Tenn. 411.
 cost of handling by different methods,
 Ohio 584.
 crop(s)—
 damage, relation to mirid plant bug,
 Wis. 546.
 emergency, comparison, [N.Y.] Cor-
 nell 53.
 emergency, in dry years, N.J. 366.
 removal, effect on soil fertility,
 Miss. 366.
 rotation, clover v. timothy as, Ind.
 659.
 variety tests, N.Mex. 366.
 curing, barn, summary, 433.
 dehydration, development of portable
 driers for, Ind. 725.
 drying in barn, studies, 127.
 fed once, twice, or three times daily to
 milking cows, efficiency of use, Idaho
 703.
 fields, residual effects of fertilizer applied
 to wheat and crop residues, Ind. 659.
 grasses, merits for landing fields, parks,
 and recreation fields, N.J. 366.
 making and storing, labor, power, and
 equipment requirements, Iowa 277.
 mixtures in Upper Peninsula, Mich. 705.
 oats-vetch mixtures v. crimson clover for,
 S.C. 367.
 production and preservation, methods,
 [N.Y.] Cornell 53.
 production, high quality, N.J. 660.
 quality in dairy rations, 105.
 seeding mixtures and techniques, [N.Y.]
 Cornell 53.
 v. grass silage for heifers, Vt. 563.
 vitamin A in, methods for conserving,
 N.J. 410.
 yield and quality on Clermont silt loam,
 effect of tile drainage, Ind. 659.
 yield from grasses, legumes, and their
 mixtures, Wis. 504.
 Haymaker, quick, experiment with, Wis. 574.
 Heats of combustion, studies, 166.
 Hedge plants for northern Great Plains, U.S.
 D.A. 676.
 Heifer(s)—
 dairy, development, Miss. 412.
 dairy, feeding and management, La. 412.
 growth rate and milk production, effect
 of rations and management, Mo. 103.
 supplements for native hay and dried beet
 pulp for, Wyo. 842.
 yearling, fattening for market, bluestem
 grass in, 98.
Hellogmodendrium hassalli in squirrels, 419.
Heliothis—
 armigera, see Bollworm, Corn earworm,
 and Tomato fruitworm.
 virescens, see Tobacco budworm.
 Hellebore, American, alkaloids of and toxicity
 to American cockroach, 249.

Helminth(s)—

- infections, natural resistance to, 110.
 of sheep and cattle, host specificity, 569.
 ova, embryonated, viability, apparatus
 for determining, 392.
 parasites of sheep, 716.
 Helminthological examinations, suspensions
 of feces for, useful mixing apparatus, 392.
Helminthosporium—
 cymbopagi n.sp., description, 533.
 tritici-vulgaris notes, U.S.D.A. 580.
Hemitarsonemus latus, see Broad mite.
 Hemlock—
 borer, studies, U.S.D.A. 88.
 Canada, effect of plant growth substances
 on rooting of cuttings, Mass. 800.
 propagation by cuttings, 376.
 western, decay, 543.
 Hemoglobin—
 formation, effect of iron, 310.
 methods of reading, comparison, 476.
 regeneration, effect of copper and iron
 on, 455.
 Hemoglobinometry studies, 620.
 Hemoglobulinuria, bacillary, new-type vaccine
 for, 162.
 Hemorrhagic disease of newborn, 896.
 Hemp—
 manilla, see Abacá.
 sun, *Fusarium* wilt, 807.
 Hens—
 laying—see also Egg production.
 ad libitum and restricted grain and
 mash feeding, Ind. 698.
 battery management in Hawaii,
 Hawaii 701.
 calcium and phosphorus balances,
 408.
 calcium metabolism in, 559.
 calcium sources for, Mass. 837.

- vitamin A in, effect of levels of shark-liver oil in ration, Fla. 842.
- vitamin C in, effect of cocoa on, Mass. 842.
- vitamin C in, effect of processing, [N.Y.]Cornell 104.

Milk—Continued.

winter, good flavor and color, feeding methods for, N.J. 410.

yields and milking rates of individual quarters of cow udder, U.S.D.A. 844.

Milking—

by machine put on time schedule, N.Y. State 845.

machines, cleaning, efficiency of methods, Ariz. 842.

plant, "Gascoigne" auto-releaser, 728.

Milkweed(s)—

as source of rubber, Utah, 676.

whorled, toxic to turkey poult, 572.

Mill streams, thiamin in, 148.**Millet**—

pearl, strain tests, Fla. 791.

strain and variety study, [N.Y.]Cornell 53.

variety tests, N.Mex. 366.

Milletia pachycarpa, insecticidal action. Conn.[New Haven] 248.**Millipedes**, relation to potato tuber defects, [N.Y.]Cornell 90.**Milo**—

Atlas and Dwarf Yellow, composition, relation to chinch bug resistance, Okla. 617.

Pythium root rot or "milo disease," 812.

Mineola vaccinii, see Cranberry fruitworm.**Mineral(s)**—

adsorption of barium and hydroxyl ions by, relation to pH, 642.

metabolism studies with artificial radioactive isotopes, 747.

nutrition of plants, Me. 197.

poisonous to livestock, Wyo. 851.

properties, functions in body, and sources, Okla. 749.

Minimum, law of, and Liebig, 616.**Minks**—

digestion of cereal starch and fiber, 407.

nutritive requirements for growth, fur production, and reproduction, [N.Y.] Cornell 85.

Minnesota Station notes, 611.**Minnesota University notes**, 611.**Mint oil**, quality and prices, Ind. 668.**Mirid plant bug**, relation to hay and pasture crop damage, Wis. 546.**Miris dolabratus**, see Plant bug, meadow.**Mississippi Station report**, 159.**Missouri Station report**, 159.**Mites**—

eriphyid, in California, 89.

injurious to domestic animals and man in New York State, 851.

of livestock, N.J. 696.

orchard, sprays for, Wash. 393.

spray mix for, Pa. 546.

Molasses—

cane, as corn substitute in ration of yearling steers, Ill. 554.

cane, in poultry ration, 838.

sugar beet, vitamin deficiencies in, Utah 259.

Molasses—Continued.

use to replace corn in poultry rations, Pa. 554.

Mold(s)—

inhibitors for food products, 741.

mycelia in butter, value of producer interviews in reducing, 107.

new antibacterial agent produced by, 487.

slime, developmental patterns in, 88.

Molecular—

still heads, designs, 474.

weights, determining, Signer method, 171.

Moles, control, Mo. 694.**Molybdenum**—

blue reaction, 173.

in legume nodules, 350.

Monetia sp. in sheep on irrigated pastures, Oreg. 856.**Monetella** mites on cigarette beetle, 823.**Monilia** sp., mode of entrance into corn ears, 383.**Monochamini** in Western Hemisphere, descriptions of new species, 549.**Monocotyledoneae**, form of vascular bundle in, 31.**Monocotyledons**, endodermis of, oxidase system associated with, 31.**Monolepis nuttalliana**, analysis, Ariz. 851.**Monomorium pharaonis**, see Ant, Pharaoh.**Montana College notes**, 611.**Montana Station notes**, 468, 611.**Montmorillonite**, test for, unreliability of benzidine color reaction, 173.**Moose diseases**, studies, 856.**Mortgage loans**, extra-risk, insurance aspects, 583.**Mosquito(es)**—See also *Anopheles*, *Culex*, and *Malaria*.

captive, water-finding and oviposition by, 402.

control, support given to national defense program in, Del. 245.

Culex, vectors of St. Louis encephalitis virus, 711.

emergency research, Iowa 247.

hosts to avian plasmodia, 302.

keg shelter as diurnal resting place, 696.

larvae, behavior, relation to surface tension of water, 96.

mechanical trap for surveys, N.J. 551.

neotropical *Anopheles*, subspecific variations and transmission of malaria by, 696.

of Ethiopian region, 551.

of Missouri, studies, Mo. 85.

studies, U.S.D.A. 89.

survey for vectors of equine encephalomyelitis, 117.

toxicity of aerosols from spraying solutions of insecticides in liquefied gas, 254.

work, outlook for, N.J. 391.

Mountain laurel, propagation, Mass. 800.

- Mourning dove production in southwestern Iowa, 391.
- Mouse embryos, homozygous yellow, development, analysis, 497.
- Mowers, horse-drawn, adapting to tractor power, Mo. 727.
- Muck deposits of New York, properties, [N.Y.]Cornell 23.
- Muck soil, effects of applying common salt on yield, composition, and quality of crops, 189.
- Mud suspensions, biochemical oxygen demand and dissolved oxygen, determination, 179.
- Mudaria variabilis*, life history and control, 402.
- Mule deer, *Oryzobacterium ovis* from, 110.
- Mules—
and horses, situation and future trends, 97.
number on Illinois accounting farms, Ill. 583.
- Mundulea scircea* from India, insecticidal properties, 825.

- Myxobacteria, biology, 34.
- Myxomycetes of Kansas, U.S.D.A. 485.
- Naphthalene—
acetamide, effect on tomato plants, 352.
and orthodichlorobenzene mixture, fumigating action, 547.
- Napier grass—
fertilizer tests, Fla. 791.
for pasture, Fla. 792, 842.
grazed by rotation, composition and grazing value, 257.
grazing tests with beef cattle, Fla. 833.
strain tests, Fla. 791.
- Narcissus—
bulb fly, methyl bromide fumigation for, 830.
bulbs, failure to bloom, causes, N.J. 371.
bulbs, prestorage disinfection of, 82.
diseases, [N.Y.]Cornell 67.
- Nasturtium, stem cuttings, adventitious roots in, 490.
- National defense and rural public assistance, 739.
- Natural resources of Venezuela, 487.
- Nectarine(s)—
bred in New Jersey, 224.
fruiting performance, effect of mild winter in California, 519.
winter chilling requirements and breeding possibilities, 519.
- Nectars of different plants, sugar concentration in, U.S.D.A. 88.
- Nectria*—
cancr f. *aurantii* n.f. on orange trees, 387.
sp. on lemon trees, 387.
- Negro scale, shipment to California, P.R. 695.
- Nematode(s)—*see also* Root knot nematode.
eggs, buoyancy, 392.
eggs in feces, counting, new apparatus for, 392.

Nematode(s)—Continued.

- giant race of, on broad beans, 533.
- hot water forced into soil for control, Ill. 546.
- meadow, studies, S.C. 378.
- parasite of whieworms, 253.

Nematodirus—

- filicollis* in sheep on irrigated pastures, Oreg. 856.
- spp. in sheep, efficiency of phenothiazine against, 423.

Neoplectana chrestima, biology and culture, 392.**Neoplastic—**

- and neoplasticlike diseases, Mass. 858.
- conditions, studies, Ind. 709.
- disease in chickens, 119.

Nephantis serinopa, bethylid parasite of, 403.**Neuroptera—**

- introduction and lists, 90.
- of British Columbia, preliminary list, 90.

Neurospora—

- genetics of biochemical characters in, 208.
- tetrasperma*, induced mutations in, inheritance, 653.

Nevada Station report, 890.**New Jersey Stations reports**, 465.**New Mexico Station report**, 465.**New York Cornell Station notes**, 324.**New York Cornell Station report**, 159.**New York State Station notes**, 324, 611.**Newcastle disease in Victoria**, 571.**Newspapers—**

- American small town weekly, source of research data, 878.
- small-town and cultural change, 588.

Nickel fungicides, mechanism of action, 380.**Nicotinamide in blood, urine, and spinal fluid**, bacterial assay method, 480.**Nicotine—**

- as insect fumigant, 825.
- free, as insecticide in nutrient solutions, Ill. 546.
- sulfate drench, composition, effect of storage, 565.

Nicotinic acid—

- chemical determination, 11, 12, 13, 14.
- determination, microbiological method, 12.
- excretion by pellagrins, 150.
- fate in man and dogs, 601.
- in animal tissues, quantitative estimation, 14.

- in blood and urine, 893.
- in flour and bread, determination, 622.
- in meat and meat products, 150.
- in rye and its milled products, 146.
- metabolism, effect of sulfapyridine on, 698.

Nigrospora spp., mode of entrance into corn ears, 383.**Nitidulidae in corn**, 247.**Nitrates**, accumulation in plants, relation to manganese deficiency, 232.**Nitrification in—**

Bedford silt loam, effect of potassium chloride, 29.

soils containing plant residues of high lignin content, Mass. 769.

Nitrogen—

and organic matter maintenance under intensive cropping conditions, Conn. [New Haven] 768.

availability studies, Tenn. 342.

calcium, phosphorus, and iron metabolism and requirements of young women, Nebr. 746.

determination, improvement in, Mo. 4.

endogenous, excretion by rats, relation to previous dietary N, 593.

fixation, detection with isotopic nitrogen, 33.

fixing organisms, hydrogenase in, 195.

in soil, effect of cropping and manure treatments, Ky. 769.

in soil, movement, effect of drought and rainfall, Ga. 770.

in soils under different soil treatment, Mo. 22.

retention, effect of calcium and phosphorus retention, 595.

retention, relation to growth and bone development in children, 595.

small quantities, iodometric estimation without distillation, 171.

sources for different vegetables, 221.

studies on Kansas branch experiment stations, 636.

supply and deficiencies of trace elements, Fla. 769.

Nitrogenous—**fertilizers—**

application to Berks silt loam soil, value, Va. 484.

on sandy soils, comparative efficiency and economy, Fla. 768.

rate of nitrification in soils from Salt River Valley, Ariz. 768.

soil and crop interrelations of, Conn. [New Haven] 774.

substitutes for, in orcharding, Mo. 670.

substances, excretion from nodules, 37.

Nodule bacteria—

and host plant, effective and ineffective association, 350.

growth in expressed juices from legume roots, 850.

"Nomersan," tests with seed-borne flax diseases, 74.

Nomophila noctuella, life history and habits, 401.

Nornicotine of Maryland tobacco, U.S.D.A. 5.

North Carolina Station notes, 468.

Nosema disease, studies, U.S.D.A. 88, Wis. 546.

Nostoc commune from 87-year-old herbarium specimen, successful revival, 194.

Nuclei, living, preparation from hen erythrocytes, 720.

Nucleoli and related nuclear structures, 494.

Nursery—

- experimental, management, Ind. 676.
- harvester, inexpensive, practical, 125.
- stock fumigation with methyl bromide, 396.
- stock fumigation with methyl bromide and HCN, Fla. 799.
- stock, growth, factors affecting, Mass. 800.
- stock inspection, 528.
- stock, inspection, certification, and transportation, Ky. 60.
- stock production, Wash. 372.

Nut(s)—

- crop insects, control, Fla. 822.
- for home planting in eastern and southeastern United States, U.S.D.A. 516.
- marketing, bibliography, U.S.D.A. 440.
- trees, varieties, Fla. 799.
- variety tests, Ill. 516.

Nutgrass control methods, Ariz. 791.

Nutrition—see also Diet(s).

- animal, *see* Animal nutrition.
- experiments, use of sulfaguanidine in, 310.
- human, in wartime, specific contribution of vegetables and fruits to, 884.
- in defense program, Utah 323.
- in health and disease, 300.
- iodine in, 497.
- plant, *see* Plant nutrition.

Nutritional—

- deficiency and infection, 110.
- deficiency disease, specific, 312.
- science and agricultural policy, 582.
- status, appraisal of, 743.
- status, medical evaluation, 741.

Nygmia phaeorrhoea, *see* Brown-tail moth.

Oak(s)—

- American, anatomical and taxonomic approaches to subgeneric segregation in, 776.
- and maple forest, root distribution and environment in, 352.
- California black, heat injury to leaves, U.S.D.A. 66.
- chestnut, for pulpwood, rapid v. slow growing, Pa. 524.
- chestnut, reproduction, response to clear and partial cutting of overstory, 526.
- fungi causing decay in East, identification, U.S.D.A. 83.

- Vicland and other, comparative merits, Wis. 504.

yields, effects of seed treatment, Mo. 67.

Odontotrema, characterization of genus and taxonomic data, 487.

Oedematocera—

- identification of species, 552.
- optata* n.sp., description, 552.

Oenothera, subgenus *Kaimannia*, cytogenetic studies, 31.

Oesophagostomum radiatum in intestines of calves, pathologic changes from, 112.

Oestradiol—

- absorption from subcutaneously implanted tablets in guinea pig, 51.
- morphogenetic actions, effect of testosterone on, 490.

Oestrin injections, effect on mouse ovary, 790.

Oestrogenic hormone in thyroidectomized rats, effect, 789.

Oestrone and stilboestrol, comparative effects on rat pituitary, 655.

Oestrus, prolonged, in rats, effect of luteinizing hormone and antigonadotropic serum 51.

Ohio Station notes, 611.

Oil(s)—see also Fat(s) and specific oils.

- development, effect on population increase and public finance, Okla. 730.
- dormant type, efficiency, relation to composition, 827.
- essential, experimental stills for, P.R. 725.
- lubricating, viscosity after hard use as key to value, Ill. 573.
- producing areas, corporate and personal property, important as sources of revenue in, Okla. 730.
- sprays, selection, Wash. 893.
- substitutes for butterfat in calf rations, 264.
- vegetable, spectral absorption studies, Ind. 616.

Oklahoma College notes, 612.

Oklahoma Station notes, 468, 612.

Old-age assistance in Iowa, Iowa 300.

Oleomargarines, local, chemical studies, P.R.U. 165.

Olive anthracnose in United States, 817.

Onion(s)—

- ascorbic acid in and distribution, 151.
- blight in muck soil, nematocides for, 78.
- breeding, Iowa 220, Mass. 800.
- bulb nematode disease, [N.Y.]Cornell 68.
- bulb rot, cause, 69.
- chemical studies, Mass. 760.
- culture, N.Mex. 371.
- diseases, Iowa 228.
- Ebenezer, effect of storage on carbohydrates, 515.
- high quality, breeding, Ill. 514.
- insects, biology and control, Iowa 247.
- produced for seed, diseases, N.Mex. 378.
- seed production, N.Mex. 371.
- seed, weak, cause of crop failures, N.Y.State 798.
- smut control, [N.Y.]Cornell 68.
- species hybrid, natural amphidiploid from, 45.
- Sweet Spanish, time of most rapid bulb development, Colo. 669.
- thrips control, Fla. 822, Mass. 820.
- thrips, studies, [N.Y.]Cornell 90.
- White Giant, improvement, N.Mex. 371.
- yellow dwarf, Iowa 228.
- yellow dwarf, insect vectors, Iowa 247.

Ooencyrtus anabitorius n.sp., parasite of Mormon cricket, 402.

Oogenesis and fertilization of mice, cytological study, 48.

Oospora pustulans, cause of potato skin spot, 545.

Opeicutelella padutckii n.g. and n.sp., description, 232.

Ophiobolus graminis, survival on grass roots, 382.

Ophthalmia—

- equine periodic, 117.
- periodic, notes, Ky. 851.
- periodic, possible relation to sensitization, 272.

Ophthalmology, vitamin B in, 147.

Opossum(s)—

- ecology, 544.
- inducing ovulation by follicle-stimulating hormone, 490.
- origin of ova in, 658.

Orange(s)—

- juice from oil-sprayed and HCN-fumigated trees, composition, 224.
- mandarin, parasite of, control, 542.
- maturity and quality standards and added color research, Fla. 760.
- moth of Dominica, 551.
- native, improvement, P.R.U. 221.
- navel, quality and yield, factors affecting, Ariz. 798.

Puerto Rican, effect of maturity on juice, acid, and sugars, P.R. 617.

Puerto Rican, wine from juice of, P.R. 617.

satsuma, rootstocks for, Fla. 799.

seasonal average f. o. b. prices, analysis, Calif. 442.

Orange(s)—Continued.

shrinkage and stem-end control, effect of washing, Fla. 760.

subfamily, three new varieties and two new combinations in, 35.

Orchard(s)—*see also* Fruit(s), Apple(s), Peach(es), *etc.*

cover crops, Wash. 372.

covers, relation to soil conservation, N.Y.State 374.

fertilization, Wash. 372.

fertilization, more scientific basis for, 671.

grass, effects of photoperiod, 203.

grass, response to temperature variations, Mo. 53.

insects, control, N.J. 391.

insects in 1941, 547.

irrigation, Wash. 372.

mulches, effect on plant nutrients in soil, Mass. 760, 800.

permanent grass cover for, Mich. 223.

pollination, natural and controlled, [N.Y.]Cornell 61.

sanitation, accessory measures in, Wash. 304.

soil(s)—

arsenic accumulations in, treatment, 161.

available potassium in, [N.Y.]Cornell 373.

management under war emergency, N.Y.State 223.

properties, in eastern Panhandle, W.Va. 484.

toxicity, Wash. 372.

spray machinery for, Miss. 863.

sprays, stickers and spreaders in, N.Y.State 815.

vegetation, Comstock mealybug on roots of, 247.

Orcharding, success in, Mich. 223.

Orchid—

chlorophyll-bearing embryos, delayed photosynthesis in, [N.Y.]Cornell 33.

culture, P.R. 668.

seed studies, [N.Y.]Cornell 33.

Oregon College notes, 468.

Oregon Station notes, 468.

Organic acids—

in plant tissues, modifications in determination, 174.

in plants, Conn.[New Haven] 760.

preserving and germicidal action on yeasts and bacteria, 763.

Organic matter—

and nitrogen maintenance under intensive cropping conditions, Conn.[New Haven] 768.

decomposition, effect of substituted cations in soil complex, 772.

development of simple test for, Wis. 483.

erosion losses of from sandy loam, 638.

in soil—

application of delignifying procedures to, 636.

Organic matter—Continued.

in soil—continued.

maintenance, Wash. 343.

methods for determination, 619.

nature and importance, N.J. 483.

Organoleptic tests, reliability, 18.

Ornamental plants, shrubs, and trees, *see*

Plant(s), Shrub(s), and Tree(s).

Ornithodoros talaje association with bats in human dwellings in Brazil, 403.

Orthodichlorobenzene and naphthalene mixture, fumigating action, 547.

Orthogonal polynomial values extended to $n=104$, tables of, Iowa 898.

Orthoptera of Arizona, Ariz. 827.

Oryzaephilus surinamensis, *see* Grain beetle, saw toothed.

Osmotic pressure of colloidal solutions, measurement, 176.

Ostertagia ostertagi—

in horses, 718.

outbreak and control, Ariz. 850.

Ova and follicle cells from germinal epithelium in ovary, origin, 655.

Ovaries—

and genital tract at and shortly after ovulation, studies, 654.

germinal epithelium proliferation, stimulation by injection of oestrone, 789.

Ovulation—

in anoestrous opossum, inducing, 499.

response in rabbit to plant juice extracts, variations, 654.

Ovulinia cauleae, notes, U.S.D.A. 243.

Oxen work on small farms, cost of, P.R.U. 284.

Oxidation reduction in soils, studies, [N.Y.] Cornell 23.

Orycanus sp., chemical control, 551.

Oxyuriasis studies, 419.

Oysters—

glycogen determination in, 336.

laboratory studies preparatory to formulation of standards, 336.

main source of food, N.J. 392.

Pachysandra stem and stolen canker, N.J. 818.

Packing house research, Fla. 760.

Paeonia californica, distribution of structural hybrids in, 40.

Paint(s)—

house and barn, classification, U.S.D.A. 128.

types for farm structures, N.J. 428.

Painting, spray, for farm buildings, 866.

Palaecrita vernata, *see* Cankerworm, spring.

Paleobotany, 485.

Palm(s)—

anatomical and developmental study, 494.

rattan, growing, P.R. 668.

seeds, handling for shipment, P.R. 668.

Palmetto, cabbage, *Laschia sabalensis* on, 543.

Palpozenillia diatraeae n.sp., new parasite of the sugarcane borer in corn, 402.

Paltis angulatis larvae, new descriptions, 400.

- Pancreas** of rat, insulin in, effect of purified pituitary preparations, 362.
- Panicaceae** tribe, cytological study of species in, 787.
- Panthea acronyctoides*** larvae, new descriptions, 400.
- Pantomorus leuocoloma***, see White-fringed beetle.
- Pantothenic acid**—
 deficiency studies in dogs, 558.
 deficient rats, porphyrin incrustations, relation to water metabolism, 600.
 effect on rat dermatitis, Mo. 147.
 in blood of mammals, 600.
 in feeding stuffs, 257.
 in nutrition of rat, 893.
 in Royal Jelly, Tex. 899.
 in rye and its milled products, 146.
 metabolism in man and rabbits, 893.
 minimum requirement for pigs, 95, 557.
 requirement of chicks, 409.
 requirement of mice, 456.
 urinary excretion by normal individuals, 456.
- Papaya**—
 diseases, 82.
 papain in, relation of total protein, P.R.U. 229.
Phytophthora parasitica on, 242.
 plants, virus infected, chemical relations in, P.R.U. 229.
 production in United States, U.S.D.A. 523.
 tests, Fla. 799.
 virus disease complex in, P.R.U. 229.
- Paper**—
 and pulp manufacture, microbiological control, advantages, 20.
 industry, bacteria in, effect of drier rolls on, 181.
 milk containers, bacterial population, relation to methods of moisture proofing, N.Y.State 848.
 products, number of bacteria in, effect of mill operations, 181.
- Paprika** varieties, N.Mex. 371.
- Papulaspora gladioli*** and *Urocystis gladioli*, morphological distinction, 381.
- Paracodrus apterogynus***, parasite of wireworms, 253.
- Paralysis**—
 Chastek, in foxes, and thiamin deficiency, 858.
 Chastek, in foxes fed on fish, 571.
 fowl, and allied conditions, etiology, Fla. 851.
 fowl and related leukemic diseases, U.S.D.A. 119.
 fowl genetic resistance to, [N.Y.]Cornell 47.
 fowl, iritis type, transmission, Iowa 270.
 fowl, studies, Ind. 709, Mo. 108, Wyo. 851.
 range, in poultry, etiology, Iowa 270.
 range, resistance to, development in poultry, Ariz. 789.
- Parasites**—
 employed in biological control, practical application of biological studies, 89.
 epiphytes, and geophytes, production of alkaloids and cyanogenetic and organic sulfur compounds, 68.
 foreign, introduction, U.S.D.A. 89.
 insect, colonization, recovery, and establishment, 89.
 laboratory propagation, place in biological control programs, 89.
- Paratetranychus pilosus***, see Red mite, European.
- Parathyroid gland**—
 and lactation in rat, 705.
 of Virginia deer at different seasons, 655.
- Paratrioza cockerelli***, see Potato psyllid and Tomato psyllid.
- Paratuberculosis**, see Johne's disease.
- Paratyphoid bacilli**, notes, Ky. 851.
- Paris-green-lime** mixtures as anopheline larvicides, concentration and distribution, 697.
- Parity** price, description and discussion, Okla. 130.
- Parlatoria ohinensis***, studies, U.S.D.A. 88.
- Parmella molliuscula*** feeding tests, Wyo. 851.
- Parsley**—
 carrot weevil as serious pest, biology and control, N.J. 696.
 Hamburg, varieties, cultivation, and food value, 589.
- Parsnips**, cooking, losses of vitamin C during, 895.
- Parthenocarp**, chemically induced in horticultural plants, Mich. 223.
- Parthoolestia parkeri*** n.g. and n.sp., new parasite of sugarcane borer in corn, 401.
- Paspalum*** spp., karology of, 204.
- Passalus cornutus***, see Horned passalus.
- Pasteurization**—see also Milk.
 and coliform organisms, 107.
- Pasteurizer**, experimental laboratory, development and use, Tenn. 411.
- Pasture(s)**—see also Grass(es), Grass-land(s), and Meadows.
 and Christmas tree plantations, combining on cut-over lands, Mich. 804.
 and forage plants, combinations of, variety tests, Ill. 504.
 composition of herbage, effect of fertilizer treatments, Me. 264.
 contour furrowing for erosion control, Mo. 120.
 crop damage, relation to mirid plant bug, Wis. 546.
 crops for irrigated areas, Colo. 507.
 dairy, returns from various types, Ill. 562.
 development, relation to soil and vegetation surveys, Fla. 768.
 experimental, measuring nutrients of, Wash. 843.
 fertilization, 52, Ill. 482.
 fertilization, relation to downward movement of lime and superphosphate, 641.

Pasture(s)—Continued.

- fertilized and unfertilized, carrying capacity for beef cattle, Ky. 834.
- grasses, *see* Grass(es).
- herbage—
 - carotene in, effect of rotational and continuous grazing by dairy cows, S.C. 411.
 - feeding value, variations in, [N.Y.] Cornell 99.
 - fertilized and unfertilized, biological analysis, Fla. 833.
 - in Alabama, composition and yield, effect of lime and fertilizer, 660.
 - production, palatability, and nutritive value, 98.
- improved, by timely mowing for weed control, Miss. 660.
- improvement studies, 98, Iowa 213, La. 411, Mo. 22.
- increasing productivity, Mo. 22.
- Kentucky bluegrass, carrying capacity, effect of grazing management, Iowa 213.
- liquid manure as fertilizer for, Wash. 343, 640.
- mixtures, botanical analysis, inclined point quadrat method, 31.
- mixtures, summer seeding v. spring seeding, Mass. 793.
- mixtures, variety tests, Idaho 659, Wyo. 793.
- native upland, v. irrigated sweetclover, for heifers, Wyo. 842.
- nutritive value to steers, fecal dry matter as index, 258.
- of different kinds, improved, costs, carrying capacity, etc. Idaho 729.
- of South Dakota, carrying capacity, S.Dak. 554.
- of southeastern Ohio, effect of locust and walnut trees, 661.
- permanent, establishment, Fla. 792.
- permanent, fertilization, Ind. 659.
- permanent, soil erosion on, Vt. 638.
- plants and mixtures, Ind. 659.
- plants, palatability, 52.
- productive value, measuring, Mo. 732.
- receiving different treatments, use by beef cattle, S.C. 403.
- replacing redtop with Kentucky bluegrass as dominant growth, Wis. 504.
- returns as pounds of milk, effects of fertilizer treatments, Me. 264.
- seeding mixtures and techniques, [N.Y.] Cornell 53.
- sheep, cleansing of helminths by cattle, 569.
- soil moisture supply on, effect of lime, N.J. 342.
- species, productiveness, effect of soil fertility, Mass. 793.
- studies, 258, Fla. 792, Ill. 504, Mo. 53, Wyo. 793.
- steep, renovation, Wis. 504.
- use to hold and enrich soil, U.S.D.A. 793.

Pasture(s)—Continued.

- vegetation, type and amount, relation to dispersion ratio, 660.
- white clover, management and returns on, Mich. 264.
- yields, measuring, clipping and grazing methods, Wash. 411.

Pea(s)—

- Alaska, weak seed cause of crop failures, N.Y.State 798.
 - aphid control—
 - improved, Wis. 546.
 - rotenone-bearing spray for, Ill. 546.
 - studies, 829, Me. 248.
 - use of dusting machines in, 399.
 - with rotenone-bearing dusts, effect of temperature and wind, 398.
 - canning, effect of borax, Wis. 513.
 - canning, fertilization, Wis. 513.
 - canning varieties of Wisconsin, tests, Wis. 801.
 - culture tests, Fla. 799.
 - diseases in Palouse section of Idaho, U.S.D.A. 66.
 - effects of boron on, Del. 212.
 - for quick freezing, best program for growing, N.J. 434.
 - frozen pack, vitamin C in, Wash. 447.
 - inoculated, effect on time of maturity, N.Y.State 222.
 - market garden, frost tolerance of strains, 59.
 - marsh spot, a manganese deficiency disease, 235.
 - marsh spot, varietal susceptibility, 383.
 - meal in poultry rations, Wash. 404.
 - nodulation, effect of seed treatment, 666.
 - preserved by frozen-pack method, ascorbic acid in, Wash. 458.
 - protein of, value, Idaho 739.
 - reduced germination in, N.Y.State 222.
 - response to auxin, effect of low intensity orange light on, 32.
 - root rot, fungi causing, N.Y.State 815.
 - seed, bacteria causing poor germination, Idaho 679.
 - seed, chemically treated, and inoculation, 539.
 - seed, responses to treatment, N.Y.State 222.
 - split seeds in, 512.
 - varieties, English, yields, Miss. 59.
 - varieties for canning, Wis. 513.
 - variety tests, Fla. 799, Wash. 367, Wyo. 793.
 - weevil control, reduced rotenone poundage possible, Idaho 694.
 - weevil, studies, U.S.D.A. 88.
 - wilts and root rots, Wis. 235.
 - yield, effect of fertilizer placement, S.C. 371.
- Peach(es)—**
- acidity and tannin in, relation to dietary value, N.J. 371.
 - aphid feeding on snapdragon, injury from, 94.

Peach(es)—Continued.

aphid, green, overwintering on Brassicæ in North Wales, 93.
 arsenical injury on, crystalline v. monohydrated zinc sulfate for prevention, 541.
 bacterial spot, culture, Del. 227.
 breeding, Ill. 516, Iowa 220.
 brown rot control, 816, N.J. 541.
 buds, opening, effects of growth substances, 62.
 canning tests, S.C. 338.
 carotenoid in, effect of processing, 455.
 cherry yellows, indexing, 691.
 Chinese, seedlings, testing, Ill. 516.
 constriction disease pathogen, ascogenous stage, 240.
 deficiency symptoms, 80.
 developed by the station, N.J. 371.
 diseases in North Carolina, U.S.D.A. 66.
 diseases in Ozark section of Arkansas, U.S.D.A. 66.
 dormant sprays on, 547.
 effect of low winter temperatures, Ill. 516.
 following total crop failure, infested with plum curculio, 247.
 fruit thinning, Ill. 516.
 fruiting performance, effect of mild winter in California, 519.
 genetic composition, Mass. 800.
 golden net virus disease, Colo. 691.
 leaf curl, dinitro sprays for, Del. 227.
 little leaf disease, Fla. 799.
 little peach disease, Del. 227, 816.
 mosaic control and eradication, U.S.D.A. 66.
 mosaic virus incubation period, 240.
 nematode-resistant, Shallit variety, propagation problems, 240.
 new commercial, bred and tested in New Jersey, 224.
 orchards, lespedeza as cover crop for, Ill. 516.
 orchards, production costs, Ill. 584.
 orchards, soil management, Ind. 668, Ky. 799, Pa. 513.
 phony disease—
 control and eradication, U.S.D.A. 66.
 in Oklahoma, U.S.D.A. 66.
 vectors, collection, U.S.D.A. 88.
 production and preservation, Wash. 62.
 rosette mosaic in the East, 81.
 scale, white, on papaya, predator of, P.R. 695.
Sclerotinia fructicola cankers on, [N.Y.] Cornell 68.
 self-fruitfulness, Del. 220.
 split-pit of and time of occurrence, 519.
 spray injury on, Del. 227.
 spraying requirements for plum curculio on, 393.
 stocks, nematode resistance in, N.J. 371.
 thinning, effects, Miss. 671.

Peach(es)—Continued.

trees, arsenic toxicity to, Idaho 679.
 trees, handling after fruit-bud winter killing, Mo. 375.
 trees, longevity in Georgia, Ga. 375.
 trees, potassium requirements, Pa. 513.
 varieties, comparative hardiness, N.J. 371.
 variety tests, Ind. 668, N.J. 371.
 wart disease, Idaho 679.
 winter chilling requirements and breeding possibilities, 519.
 X-disease—
 absence from State, Del. 227.
 chemotherapeutic tests with, Conn. [New Haven] 805.
 prevalence, Wash. 378.
 review of present knowledge, 541.
 studies, Colo. 691, [N.Y.] Cornell 68, U.S.D.A. 88.
 western, in Oregon, U.S.D.A. 377.
 western, in Utah, 387.
 western, virus-induced, Idaho 679.
 yellow freestone, adaptability for canning, Wash. 451.
 yellow-red virosis, see Peach X-disease.
 yellows, studies, Del. 227, 816.
 Peachtree borer—
 control, 547, Ill. 540.
 control, ethylene dichloride emulsion for, Del. 245, Mass. 800, U.S.D.A. 88.
 ethylene dichloride and paradichlorobenzene crystals for, N.J. 391.
 treatments, injury from, 247.
 Peanut(s)—
 as feed for swine, deficiencies, Fla. 833.
 breeding, Fla. 791.
 Cercospora leaf spot control, 67, Fla. 806.
 culture tests, Fla. 792.
 diseases in Georgian S. S. R., 529.
 diseases in North Carolina, U.S.D.A. 66.
 growing to meet war needs, Miss. 660.
 hay for fattening steers, Fla. 833.
 increased acreage asked to meet war needs, Miss. 213.
 inoculation methods, Fla. 792.
 leaf spot control, Va. 534.
 leaf spot control in Brazil, 534.
 meal for dairy cattle, 410.
 meal in swine ration, Ga. 836.
 production—
 for oil in national defense program, 510.
 for war needs, Ga. 132.
 machinery in, 124.
 notes, Miss. 370.
 ring spot, symptoms, 235.
 runner, and corn, rotating with native cover crops, Fla. 792.
 Spanish, increased yields by dusting, Ga. 235.
 Stegasta bosqueella, micro leaf worm on, 247.
 variety tests, Fla. 791.
 verruccosis, 235.

Pear(s)—

- Anjou, cock spot of, Wash. 378.
- Bartlett, auction prices, relation to supplies, Calif. 442.
- Bartlett, black end of, Wash. 378.
- Bartlett, market quality, relation to ripening temperature, 518.
- breeding, Iowa 220.
- buds, opening, effects of growth substances, 62.
- fire blight, Idaho 679.
- fire blight-resistant, development, Tenn. 371.
- fire blight, varietal susceptibility to, S.Dak. 528.
- irrigation experiments, Calif. 518.
- pollen, useful abnormality of, 672.
- practices to induce early and regular bearing, [N.Y.] Cornell 61.
- psylla—
 - control program, 395, 824.
 - in Northwest, U.S.D.A. 88.
 - survey, Wash. 394.
- refrigerated gas storage, 673.
- respiration, relation to ethylene production, 355.
- spray injury, 528.
- storage, 802.
- tree insects in central Washington, 394.
- vitamin C in, Wash. 447.

Pearl, R., contributions to poultry science, 259.

Peat—

- deposits of Louisiana, La. 633.
- deposits of New York, properties, [N.Y.] Cornell 23.
- moss as soil amendment for roses, 226.

Pecan(s)—

- climatic requirements in Yuma Valley, Ariz. 798.
- groves, cooperative fertilizer tests in, Fla. 799.
- grown under irrigation, food value, N. Mex. 327.
- growth and production, relation to nitrogen absorption and storage, Fla. 799.
- harvesting dates, Ariz. 799.
- nuts, filling, factors in, Ariz. 799.
- orchards, cover crop tests in, Fla. 799.
- rosette in mature trees, zinc sulfate treatments for, 817.
- trees, delayed foliation in Arizona, 675.
- Ariz. 799.
- trees, top-worked, care of, Miss. 675.
- trees, top-working methods, Ariz. 799.
- trees, unfruitful or inferior, effect of top-working, Miss. 221.
- varieties, Fla. 799, N.Mex. 371.
- winter dormancy, relation to sunshine, Ariz. 799.

Pectin—

- compositions, public service patent on, Del. 165.
- decomposition, role of intestinal bacteria in, 141.
- demethylation, effect on jellying properties, Del. 17.

Pectin—Continued.

- ingested, fate of, 142.
- ingested, metabolism of, 504.
- partial demethylation, Del. 165.

Pectinophora gossypiella, see Bollworm, pink.

Pellagra, excretion of nicotinic acid in, 150.

Pemphres affinis parasites in India, biology and distribution, 400.

Penicillin—

- and gramicidin, comparative bacteriostatic activity, 33.
- antibacterial action, 33.

Penicillium, mode of entrance into corn ears, 383.

Pennsylvania Station report, 609.

Penny cress seed germination, 512.

Pentilia castanea, scale predator, notes, P.R. 695.

Peony(ies)—

- anthracnose in Illinois, U.S.D.A. 680.
- bud blast, N.J. 818.
- measles, control program, 244.
- testing for heat resistance and use as cut flowers, Iowa 220.

Pepper(s)—

- breeding, Conn.[New Haven] 790.
- chile, as sources of carotene and ascorbic acid, N.Mex. 446.
- diseases in North Carolina, U.S.D.A. 66.
- flower bud moth, studies, P.R.U. 248.
- mosaic-resistant, P.R.U. 229.
- mosaic studies, P.R.U. 386.
- mulching, Mass. 800.
- Perfection pimiento, fruit growth, 60.
- pimiento, mosaic-type virus disease of, control, P.R.U. 815.
- rot due to a *Botrytis* with sclerotial stage, 539.
- Rutgers World Beater No. 13, value, N.J. 371.
- weevil, Fla. 822.
- yield, effect of methods of growing and transplanting, 59.

Peppergrass, perennial, root system, 31.

Peppermint—

- anthracnose control, Ind. 679.
- new disease in Indiana, Ind. 679.
- oil, yield and market value, factors affecting, Ind. 180.

Peregrinus maidis—

- in New Jersey, 93.
- notes, P.R.U. 394.
- transmission of wallaby ear disease of corn by, 812.

Peridermium strobi, see White pine blister rust.

Peridental tissues, effect of prolonged vitamin deficiencies, 598.

Perilla culture tests, Ill. 504.

Perilla variety tests, Ill. 504.

Periplaneta americana, see Cockroach, American.

Pertisera nepentidis, life history, distribution, and economic importance, 408.

Periwinkle—

- false blossom cure by heat, 244.
- infected with aster yellows, heat cure, 83.

- Peronospora* spp. spore dispersal, mechanism, 536.
- Perosis in chicks—**
control, 560.
relation to biotin, Mo. 830.
sunlight as preventive, Wis. 555.
- Peroxidase in different tissues of citrus fruits,** 490.
- Persimmon—**
brownish sooty mold, 242.
native, data, U.S.D.A. 675.
polyploidy in, 45.
- Pest control, patents relating to, U.S.D.A. 87.**
- Petri dish—**
cover, new, and technic for use in cultivation of anaerobes and microaerophiles, 485.
holder for mechanical stages, 495.
- Petroleum oils as insecticides, dormant type, efficiency, relation to composition, 827.**
- Petunia—**
dodder on, U.S.D.A. 805.
leaf curl, new strain, 76.
pollen, X-ray treatment of, cytological irregularities induced by, 46.
- Phacidium nigrum* on *Xolisma ferruginea*, 381.
- Phaeosaccardinula javanica* n.comb. on persimmon, 242.
- Pheasant(s)—**
aberrant plumage colors in, [N.Y.] Cornell 47.
fall feeds, Pa. 546.
management, Iowa 245.
- Phenols—**
bactericidal activities, effect of temperature, 486.
in vanilla extract, determination and significance, 337.
- Phenothiazine—**
as anthelmintic, 852.
as anthelmintic for horses, 117, 857.
as anthelmintic for large animals, 271.
as anthelmintic for sheep, 116.
failure as anthelmintic in Oregon sheep, 116.
incorporated in sheep feed or lick, possible anthelmintic value, 856.
poisoning in pigs, 274.
- Phenylacetic acid, effect on tomato plants,** 352.
- Philaenus spumarius*, notes, Del. 245.
- Phloem necrosis, virus disease of American elm, U.S.D.A. 692.**
- Phlox powdery mildew—**
notes, Mass. 807.
resistance, 388.
- Phlyctocytrium lippellii* n.sp., notes, 381.
- Phomopsis—**
citri and *Diplodia natalensis* as cause of citrus disease, comparative behavior, 542.
juniperovora blight of white cedars, 229.
sp. collected on citrus plants in Brazil, 542.
vesans, perfect stage of, 538.
- Phoradon humuli*, see Hop aphid.
- Phosphatase—**
activity, comparative, of skim milk, whole milk, cream, and butter, Iowa 263.
excretion, fecal, and calcium and nitrogen balance of rats, 453.
reaction of butter, effect of storage conditions, Ind. 704.
test, extent of use in North America, 707.
- Phosphate(s)—**
adsorbed, from kaollinite by fluoride, replacement, 29.
bond energy, metabolic generation and utilization, 471.
effect on hardness of soil, 189.
- fertilizers—**
comparison, Iowa 183.
effectiveness, field tests, Ky. 345.
field test of, Pa. 641.
problem of, Ill. 640.
fixation in New Jersey soils, variation in, N.J. 342.
in Iowa soils, determination, Mitscherlich method for, 618.
method of application, N.J. 342.
rock, reaction with P_2O_5 , 30.
value as plant food source, Miss. 632.
- Phosphate-lime studies, Tenn. 312.**
- Phosphorus—**
and calcium retention, effect of nitrogen retention, 595.
and calcium studies in normal adults, 451.
calcium, iron, and nitrogen metabolism and requirements of young women, Nebr. 746.
ceruleomolybdate determination, 618.
compounds in Kentucky soils, Ky. 769.
fertilizers, new, Tenn. 343.
fixation, effect of soil temperature, 641.
lays, low and high, nutrition studies with rats and calves, Tenn. 404.
in biological materials, determination, 332.
in lamb and steer rations, Idaho 697.
in soils, determination, provision for eliminating interference of arsenic, 478.
in soils, forms, and availability to plants, Iowa 183.
organic, in soils, extraction and separation, 174.
organic, in soils, nature and decomposition in soil cultures, 188.
organic, v. superphosphate in plant nutrition, 641.
retention, relation to growth and bone development in children, 595.
roughages, high and low, for steers, Tenn. 404.
sources, effect on cigar-leaf tobacco, Conn. [New Haven] 796.
turn-over of rat skeleton on normal and rachitogenic diets, effect of pregnancy, 311.
- Photoperiodic aftereffect, 784.**

Photosynthesis—

and absorption in blue radiation, 649.
bacterial, and importance for general problem, 471.

CO₂ evolution during induction period, 649.

CO₂ exchange and measurement of quantum yield, 42.

chemical energy of, 42.

depressant effect of carbon dioxide, 202.

facts and interpretations, 471.

fundamental investigations, results, 485.

inhibitory effects of inorganic compounds, 493.

of greenhouse roses, effect of sprays, Ohio 203.

quantum efficiency of, 485.

rate in legumes supplied with free or bound nitrogen, 784.

studies, Ind. 616.

use of radioactive CO₂ in, 485.

o-Phthalaldehyde solution as glycine reagent, preparation, 179.

Phycomyces—

guanline and factor Z₁ as growth substances for, 194.

hypoxanthine as growth substance for, 645.

Phyllachora cynodontis, new fungus on *Muhlenbergia schreberi*, U.S.D.A. 377.

Phyllanthus nummulariaefolius in United States, 348.

Phyllobius spp. on cultivated fruit trees in Great Britain, 400.

Phyllocoptes oleivorus, see Citrus rust mite.

Phyllophaga—

distribution, descriptions, and records, 549.

inopia n.sp., description, 549.

sylyatica n.sp., description, 549.

Phyllosticta n.spp. on western Gramineae, 72.

Phymatotrichum—

omnivorum, utilization of inorganic nitrogen by, 234.

root rot, new host plants subject to, U.S.D.A. 680.

root rot of pecan trees, control, Ariz. 805.

Physaloepera—

rhodina, life history and taxonomy, Fla. 808.

zeicola, notes, 234.

Physcus testaceus, introduction into California, 821.

Physiographic correlations, Ariz. 859.

Physoderma zeae-maydis, notes, 234.

Phytic acid and the preparation of food, 594.

Phytohormones, control of flowering with, 770.

Phytomonas—

alliiicola n.sp., description, 69.

caryophylli n.sp., description, 68.

corylina, notes, 242.

genus, lipolytic activity, 809.

incanae n.sp., description, Calif. 692.

manihotus, description, 69.

Phytomonas—Continued.

manihotus, nomenclature, classification, and physiology, [N.Y.]Cornell 67.

matthiolae, notes, 244.

n.spp., nomenclature, classification, and physiology, [N.Y.]Cornell 67.

solanacearum, notes, N.J. 877.

spp. infecting tobacco leaves, relation to moisture, 383.

spp., notes, Pa. 686.

tumefaciens, notes, 689.

viburni, notes, U.S.D.A. 805.

Phytophaga destructor, see Hessian fly.

Phytophthora—

citrophthora on citrus, 81.

crown rot of loquat, 387.

fruit rot of tomato, 229.

infestans, see Potato blight, late.

lateralis n.spp., studies, 381.

parasitica on papaya, 242.

spp. on avocado and walnut, 242.

spp., oospore formation in paired cultures, 81.

Pickles—

and the national diet, 887.

quality, production, disease control program for, 18.

sweet, bloater formation in, 19.

Pickleworm control, S.C. 393.

Pig(s)—see also Sows and Swine.

breeding Landrace-Duroc and Chester

White and their crosses, Ind. 655.

breeding stock evaluation, Iowa 209.

brooders, Wash. 428.

charcoal in rations for, value, [N.Y.]Cornell 99.

crossbred and purebred, relative mortality, S.C. 403.

crossbreeding in, value, Ill. 788.

crosses, differences between, Iowa 209.

cut-out profit or loss on, Iowa 283.

development, effect of sex, 209, 210, 657.

disease of sucklings, Ill. 564.

Duroc, weight and market score, heritability of differences in, 209.

early spring farrowed, use of electric heat in brooding, Ind. 725.

embryo, double notochord in, 655.

fattening—

and growing rations, calcium and phosphorus relations, 98.

comparison of ground and whole
Sooner mlo with corn for, S.Dak. 554.

economy of gains made by, factors affecting, S.C. 403.

Mississippi-grown feeds for, Miss. 836.

rations for, Fla. 834.

feeding experiments in Irish Free State, 259.

feeding, protein supplements for, Calif. 407.

feeding zinc to, 856.

growing-fattening, protein needs of, Ill. 554.

Fig(s)—Continued.

- hemophilia-like conditions in, inheritance, 861.
- improved strains for American conditions, value of Danish Landrace breed in, Iowa 209.
- improving native stock in Puerto Rico, P.R.U. 407.
- inbred lines, experimental design for testing, 209.
- inbred lines, trends in, 209.
- incubated eggs for and feeding methods, 101.
- Large White breed, longevity and interval between generations, 210.
- market—
 - cause for losses and shrinkage, Ind. 698.
 - crossbreeds for production, S.C. 404.
 - feed requirements, tentative standard, 701.
 - feeding and management, Wis 259.
 - grades, feed requirements, Fla 833.
 - rations for, Mo. 99.
 - types and grades, Ind. 698.
- nutrition, role of fat in, Ind. 697.
- nutritional deficiencies of concentrate mixture, 98, 557.
- of Iowa, factors affecting grade, Iowa 283.
- on alfalfa pasture, proso, corn, and barley as feeds for, N.Dak. 836.
- pantothenic acid for, minimum requirement, 557.
- peanuts as feed, deficiencies of, Fla. 833.
- phenothiazine poisoning, 274.
- Poland China—
 - effect of inbreeding, Iowa 209.
 - heritability of conformation, 656.
 - large and small type sexual development, 209.
- prices and corn prices and expectations, Iowa 283.
- production in Florida, Fla. 102.

 role of insects in spread, 229.
 survey, Wash. 378.
 Survey, Canadian, report, 807.
 survey, findings in, Iowa 228.
 virus, of potato group, Wash. 378.
 distribution and ecology in waterfowl breeding areas, Iowa 191.
 drug, *see* Drug plants.
 edible wild, available in Alabama, Ala. 589.
 effect of soil air, Miss. 27.
 effect of various growth substances, 38.
 examination for insecticidal constituents, 825.
 extracts, spectroscopic analysis for chlorophylls a and b, 333.
 flowering—
 and ferns of Arizona, U.S.D.A. 347.
 and nonflowering, mineral pattern, 32.
 interspecific hybridization in, endosperm as barrier, 46.
 winter lighting, Wash. 428.
 for soil conservation purposes, adaptation studies, Iowa 191.
 greenhouse, diseases, Wash. 378.
 greenhouse, method of watering, [N.Y.] Cornell 64.
 groups, boron distribution among, 354.
 growing in containers, distribution of moisture for, 27.

Plant(s)—Continued.

growing, limitations of auto-irrigators for controlling soil moisture under, 781.
 growing season, average, and departures therefrom, Mich. 766.
 growing under different light conditions, development, effect of mineral nutrition, 783.
 growth—
 and development, effect of photoperiodic induction with constant and intermittent light, 357.
 and development, symposium, 38.
 effect of arsenious, arsenic, and antimony oxides, Mass. 769.
 effect of fluorescein on, 780.
 effect of waste sulfate liquor, 347.
 habit, effect of light, 40.
 hormones, extraction, 38.
 limitation by magnesium and minor element deficiencies, differences in, 108.
 of leaves and stems, tomato test for factors limiting, 32.
 patterns in, 38.
 relation to pH value, 771.
 reproduction, and composition, effect of mineral elements, Fla. 760.
 growth substances—
 and growth curvatures, 38.
 for seed treatment of sugar beets, Mich. 194.
 injections in rats and chick embryos, 655.
 newer applications of, 347.
 synthetic, effect on cuttings and seeds, 221.
 hardy perennials, blooming dates, Mass. 803.
 hedge, for northern Great Plains, U.S.D.A. 676.
 herbaceous, high-phosphate starter solutions for, [N.Y.] Cornell 64.
 hormones, *see* Plant growth substances.
 hunters in Andes, 347.
 insecticidal and piscicidal, of India, 86.
 intake of elements applied to soil in pairs v. singly, Mass. 800.
 invertase action in, alterations of prevailing direction, 489.
 juice extracts, ovulation response in rabbit, 654.
 juices, sex maturity factor in, 654.
 living, enzymic processes in, 471.
 macroscopic photoperiodic aftereffects in, 80.
 magnesium requirements, Mass. 800.
 manganese deficiency in, relation to accumulation of nitrates, 282.
 material(s)—
 ascorbic acid in, photometric determination, 15.
 ashing conditions, relation to mineral elements in ash, 838.

Plant(s)—Continued.

material(s)—continued.

- analysis, rapid chemical methods, 174.
- decomposition, Iowa 183.
- extraction of carotene from, 763.
- herbaceous, variety tests, Mass. 800.
- introduced for testing, U.S.D.A. 484.
- new introduction and distribution, P.R. 668.
- sodium determination in, 333.
- metabolism, boron and calcium in, relation, N.J. 371.
- mineral nutrition of, Me. 197.
- mineral requirements, indicated by solution cultures, 616.
- minor growth substances in, effect of vernalization and photoperiodism, 780.
- mitotic periodicity in and respiration, correlation, 31.
- monocots, types of vessels in various organs of, 651.
- monocotyledonous, endodermis development, relation to an oxidase system, 205.
- nitrate and ammonium nitrogen absorption and use by, effect of oxygen supply, N.J. 342.
- nitrate nitrogen utilization by, relation to phosphorus supply, N.J. 342.
- nutrient substrates for, significance of oxygen in, 492.
- nutrients, erosion losses of from sandy loam, 638.
- nutrition—
 - and adsorbed ions on colloidal complex, 772.
 - and pH, 186.
 - and physiology under artificial light supplementing daylight, Ind. 649.
 - efficiency of organic phosphorus v. superphosphate in, 641.
 - fresh water phytoplankton for, 485.

virus diseases, distribution in Philippines, 69.

viruses, serological studies, 530.

viruses, ultrafiltration studies, 69.

vitamins in, effect of cultural treatment, Mo. 145.

water absorption by, effect of composition of soil atmosphere, 32.

with small chromosomes, schedule used for somatic counts, 358.

woody, *see* Woody.

zinc deficient, vacuoles in cells of, catechol aggregates in, 809.

Plantain, English, cytological-histological study, 785.

Plasma proteins, properties and functions, 141.

Plasmodiophorales, host index, bibliography, and description of diseases caused by this order, 808.

Plasmodium—

catemerium, 3H2 strain in canaries, course of infections, 724.

gallinaceum, continued passage of extra-erythrocytic forms, 119.

gallinaceum, mosquito hosts to, 392.

lophurae in ducks, host-parasite relation of untreated infections, 859.

Plastic wastes as fertilizers, value, N.J. 342.

Platygodidae, food plant relations in Hawaii, 546.

Pleospora herbarum from red clover seed, 683.

Plesiocoris rugicollis, control on apples, damage from, 396.

Pliofilm wrappers for Florida fruits and vegetables, Fla. 372.

Plodia interpunctella, *see* Indian-meal moth.

Plow(s)—

adjustment and operation, Mo. 727.

draft increase due to parasitical friction, Pa. 573.

fertilizer attachment for, Ind. 725.

trash shields, studies, Ind. 725.

Plum(s)—

aphid control with dinitroresol, 396.

breeding, Iowa 220.

curculio—

control, Tenn. 393.

control, dichloroethyl ether for, U.S.D.A. 88.

in apples, control, Mass. 820.

jarring for control, Ill. 546.

on peach following total crop failure, 247.

on peaches, spraying requirements, 393.

diseases in Ozark section of Arkansas, U.S.D.A. 66.

effect of low winter temperatures, Ill. 516.

golden net virus disease, Colo. 691.

growth, Iowa 220.

mature, framework grafting, 670.

thinning, effects, 671.

variety tests, Ind. 668.

wild, brown rot, U.S.D.A. 805.

Plywood use in hog and poultry houses, structural and economic factors, Ind. 725.

Pneumococci, sulfonamidefast, response to penicillin, 710.

Pneumoenteritis of calves, filtrable virus from, 115.

Pneumonia—

in food-producing animals, pathology of, 712.

of calves, filtrable virus from, 568.

of calves, sulfapyridine in treatment, 115.

Poinsettia—

diseases, new, in Gulf coast area, 245.

scab, Fla. 806.

scab in Honolulu, 244.

Poison dusts, daytime use, Miss. 695.

Poison mixtures, toxicity tests, analysis, 825.

Poison-ivy control with ammonium sulfamate spray, Wis. 505.

Poisonous plants, *see* Cattle poisoning,
Plants, poisonous, and specific plants.

Poliomyelitis—

insects and epidemiology, 395.
relation to housefly control, 553.
rodent, 567.
virus from flies, 553.

Pollen—

chemical analyses and feeding experi-
ments with bees, U.S.D.A. 88.
growth studies, 195.
reserves of bees, U.S.D.A. 88.
tube culture, 780.

Polychrosis viteana, *see* Grape berry moth.

Polymbryony in *Asparagus officinalis*, cyto-
genetic studies, 31.

Polygonatum, cytological basis for speciation
in systematic study, 32.

Polyploidy—

induction in *Vinca rosea*, 31.
studies with wheat, Mo. 52.

Polyporaceae of Pennsylvania, Pa. 644.

Polyporus—

betulinus, life cycle, 31.
spp. on sprout oak stands, U.S.D.A. 84.
schweinitzii red-brown butt rot on west-
ern hemlock, 543.
sulphureus brown cubical rot on western
hemlock, 543.

Polysaccharides, plant, structure of, 783.

Polystictus abietinus pitted sap rot on west-
ern hemlock, 543.

Poncirus trifoliata disinfection of seed and
roots, 529.

Pond, small artificial, income possibilities
from, 545.

Ponds and lakes, uses and management,
N.Dak. 820.

Popcorn breeding Ind. 659.

Popcorn variety tests, Ind. 659.

Popillius disjunctus, *see* Horned passalus.

Popillia japonica, *see* Japanese beetle.

Poplar, yellow, plantings on adverse sites,
fertilizer tests, 677.

Poppy—

bacterial soft rot, causal organism, 83.
California, nomenclature, Ariz. 776.
diseases in Oregon, U.S.D.A. 805.

Population—

change, geography of, in Canandaigua
Lake region, New York, 586.
changes in New York and significance
for local government, [N.Y.]Cornell
445.
farm, of North Dakota, papers on, N.Dak.

tries as defense-boom workers, 737.
of Kentucky, growth, 1880-1940, Ky. 877.
redistribution in Louisiana, 877.

Poria—

colorea n.sp. spongy butt rot on western
hemlock, 543.

Poria—Continued.

genus, index and key to species, Pa. 644.
spiculosa n.sp. in Hickory and oak, 389.
spp. on sprout oak stands, U.S.D.A. 84.
subacida feather rot on western hemlock,
543.

Pork—

changes during freezing and storage,
Ind. 697.
diet, pregnancy disorder induced by,
modifications in blood, urine, and tis-
sues of rats on, Iowa 303.
diets, toxemic pregnancies induced by,
production and cure, Iowa 303.
effect of temperature on grades held in
storage, Iowa 257.
flavor, effect of fish meal and fish oil,
Ind. 697.
frozen, palatability, cooking losses, and
tenderness, Ind. 740.
muscle, autoclaved, biological value,
Iowa 303.
nicotinic acid in, 150.
production, emergency, Mo. 406.
products, oat flour as preservative for
fat in, Ill. 554.
quality, effect of hominy feed on, Ind.
697.
quality, produced on pasture, S.Dak. 554.
quality, role of fat in, Ind. 697.

Porphyrim incrustations in pantothenic acid-
deficient rats, relation to water metabo-
lism, 600.

Porthecria dispar, *see* Gypsy moth.

Potash—

and lime studies, Tenn. 342.
in fertilizers, determination, effect of
temperature of alcohol, 174.
residual value, Ill. 482.

Potassium—

availability in orchard soils, [N.Y.]Cor-
nell 373.
availability in soil types, Iowa 183.
determination by cobaltinitrite method,
effect of temperature and pH. 477.
determination with dipicrylamine, 477.
dichromate, selective bacteriostatic ef-
fect of, 192.
dipicrylamine, photometric determina-
tion, 172.
exchangeable, in Alabama soils, relation
to needs of cotton, 345.
fertilizer, most economical form, Miss.
189.
in biological materials, determination,
172.
in bone and tooth substance, spectro-
chemical studies, 462.
in fruit products, determination, 337.

Potato(es)—

aphid injury, varietal susceptibility, 251.
aphids, studies, U.S.D.A. 88.
bacterial brown rot control, Fla. 806.
bacterial ring rot, classification and
nomenclature of pathogen, 383.

Potato(es)—Continued.

- bacterial ring rot—continued.
 control, 535, Me. 228, W.Va. 236.
 identification, Wis. 528.
 in Arizona, Ariz. 805, U.S.D.A. 805.
 in late crop seed, 75.
 prevention of spread on cutting
 knife and early symptoms, Idaho
 679.
 bags, washing and sterilizing, N.Dak. 686.
 baked, scoring for texture, 139.
 blackening on boiling, cause, 448.
 blackleg control, 236.
 blight, epiphytotic of in Argentina, 534
 blight, late—
 control in an epidemic year, 534.
 first report in Colorado, U.S.D.A. 66.
 in New York, U.S.D.A. 805.
 reports, U.S.D.A. 680.
 spraying for, Me. 228.
 studies, U.S.D.A. 805.
 blight-resistant varieties, new, 534.
 Bliss Triumph, Dakota seed of, treat-
 ment, Fla. 791.
 borax studies with, Mass., 793.
 breeding, Idaho 659, Ind. 659, Iowa 212,
 [N.Y.]Cornell 53, Wash. 367, Wyo. 793.
 certification work with, Wyo. 793.
 Cobblers, ethylene chlorohydrin treat-
 ment, Me. 228.
 composition and nutritive value, Mass.
 605.
 cooked, blackening, properties of pig-
 ment, 887.
 cover crops, rotation, and soil reaction
 tests, [N.Y.]Cornell 53.
 crop and wireworms, 253.
 Cu-lime dust effective on, N.J. 378.
 cull grades of, causes for, Idaho 729.
 culture in Iowa, Iowa 217.
 culture tests, Fla. 792, Idaho 659, Tenu.
 367, Wyo. 793.
 deep scab studies, Wis. 528.
 degeneration in São Paulo, virus Y one of
 chief causes, 535.
 diseases—
 control, Fla. 806, Mont. 812.
 in Idaho, 74.

 in Massachusetts, U.S.D.A. 805.
 in North Carolina, U.S.D.A. 66.
 losses caused in Hastings Section,
 Florida, U.S.D.A. 680.
 spray tests for, Me. 228.
 virus, Wash. 878.
 virus, studies with tuber-line seed
 plats and insects, Me. 685.
 dried, ascorbic acid in, 751.
 early, experiments on sandy loam, Ohio
 510.
 enterprise in Garrett County, Md. 132.
 fall-crop Irish, production, Okla. 665,
 666.
 feeding to growing chickens, 260.
 fertilizer tests, Fla. 791, Idaho 659, Me.
 213, Mo. 53, N.J. 366, [N.Y.]Cornell
 53, Tenn. 367, Wyo. 793.

Potato(es)—Continued.

- fertilizer-cover crop experiments and
 nutritional sprays, Fla. 791.
 flea beetle—
 biology and control, Wash. 394.
 on cigar-type tobacco in South,
 U.S.D.A. 394.
 studies, Conn.[New Haven] 822,
 U.S.D.A. 88.
 western, studies, U.S.D.A. 88.
 flower and berry production, relation to
 photoperiod and supplemental light
 intensity, 204.
 foundation seed, roguing service for pro-
 ducers, Me. 213.
Fusarium wilt, extensive occurrence,
 Idaho 679.
 grade, storage, and cooking quality
 studies, Idaho 659.
 green manure tests, Me. 213.
 Green Mountain tuber-line seed plats, re-
 lation to viroses, Me. 228.
 green-sprouting treatment, Mo. 53.
 improvement by food-for-freedom pro-
 gram, Colo. 665.
 insects, 248, N.Dak. 248.
 insects on Long Island, [N.Y.]Cornell 90.
 insects, survey, Iowa 247.
 iron in, effect of cooking method, 886.
 irrigation, value in New Jersey, N.J. 428.
 irrigation with cold well and warmer
 canal waters, Idaho 724.
 jell end rot, effect of moisture supply,
 Idaho 679.
 Kansas, market preferences and quality
 analysis, Kans. 298.
 late-crop, retail trade practices and pref-
 erences in Chicago, U.S.D.A. 299.
 leaf extract and entire leaf as index of
 soil fertility, 783.
 leaf roll, varietal susceptibility and effect
 on yield, 534.
 leaf roll virosis, tests for resistance to,
 Me. 228.
 leafhopper, hibernation, N.Dak. 248.
 leafhopper on peanuts, control, Va. 534.
 manganese-deficiency disease on burned
 peat soil, Wis. 528.
 marketing by Ohio Farm Bureau Co-
 operative, U.S.D.A. 440.
 mechanized production, Idaho 725.
 methods of ensiling, Idaho 703.
 Netted Gem, cooking quality, effect of ir-
 rigation, Wash. 447.
 new chlorinated lime treatment for,
 N.Dak. 75.
 new form of low-temperature injury in,
 812.
 new, handling and shipping tests, Calif.
 580.
 new wild species from Argentina and
 Uruguay, 487.
 plants, effects of insect attacks, [N.Y.]
 Cornell 90.
 pollen, germination, simple method for,
 191.

Potato(es)—Continued.

- Prairie(s)—
 - of Louisiana, isolated, 32.
 - soil as medium for tree growth, 65.
 - soils, black, chemical composition of clay fractions, 184.
 - soils, role of soil bacteria as direct factor in aggregation of, 773.
- Precipitation—*see also* Rainfall, Snow, *etc.*
 - and temperature conditions in Dominican Republic, 182.
 - hourly, on Upper Ohio and Susquehanna Drainage Basin, U.S.D.A. 768.
 - in Muskingum River Basin, U.S.D.A. 340.
 - percentage, seasonal, maps of, 631.
- Pregnancy in mare, chemical test for, Mo. 47.
- Pregnant mare serum, response of hypophysectomized male guinea pigs to, 654.
- Preservative liquids in sealed vials, adding or changing without removing cork, 90.
- Pressure cooker—
 - gages, reliability, Wyo. 880.
 - steam, studies, 898.
- Prices—
 - and currency depreciation, [N.Y.]Cornell 130.
 - and price indexes, tables, Okla. 435.
 - effects of exchange depreciation, [N.Y.]Cornell 876.
- Privet, *Cercospora* leaf spot of, 229.
- Prodenia eridania*, *see* Armyworm, southern.
- Production, effects of exchange depreciation, [N.Y.]Cornell 876.
- Progesterone—
 - administration to mouse, maintenance of deciduomata in, 654.
 - effect on male and female mice, 502.
 - effect on uterus of mice, 654.
 - metabolism, 789.
- Propaganda, sociological analysis, 879.
- Propylene glycol, continued administration, results, 451.
- Proso, turkey-ing-off, S.Dak. 703.
- Prostatic tissue from male and female rats, comparison of reactions, 658.

Protein(s)—

and metaphosphoric acid, combination, 166.

biological value, effect of level of calcium intake, 142.

chemistry of, and Liebig, 616.

chemistry of, recent advances in, 166.

clay-adsorbed, resistance to proteolytic hydrolysis, 185.

crystalline, of cucurbits, Conn.[New Haven] 760.

from various sources, nutritive value, [N.Y.]Cornell 99.

intake, effect on growth, reproduction, and longevity at different calcium levels, 453.

intake, relation to calcification rate during growth, 452.

iodinated, feeding, effect on milk production, 705.

percentages for egg production, S.Dak. 554.

serum, genic effects, 49.

structure, 471.

Proteinases, specificity, 471.**Prothrombin—**

clotting times in newborn infants, clinical studies, 155.

concentration in blood of various species, 461.

deficiency in newborn, antepartum use of vitamin K for prevention of, 156.

in newborn infant, 461.

levels in the newborn, simplified determination, 309.

purification, 166.

Protoparce sexta, see Tobacco hornworm.

Protoplasm structure, symposium on, 649.

Provitamin A—

in American whole wheat flour and bread, 145.

in watermelon, 312.

Prune(s)—

juice experiments, 17.

nectar as new Idaho product, Idaho 616.

variety tests, Ind. 668.

Psalliotia campestris, secondary spores in mycelium, 644.

Psallus seriatus, see Cotton flea hopper.

Pseudaulacaspis pentagona, see Peach scale, white.

Pseudococcus—

brevipes, see Mealybug, pineapple.

comstocki, see Mealybug, Comstock.

cuspidatae, pest of genus *Taxus*, 828.

nipae, see Mealybug, coconut.

Pseudomonas—

aeruginosa, plant pathogen, 70.

fluorescens, notes, Pa. 686.

lipolytic activity, 809.

putrefaciens, relation to surface taint in butter, distribution and sources, Iowa 263.

Pseudophycus utilis, parasite of coconut mealybug, effective use, P.R. 695.

Psittacosis and meningopneumonitis virus, comparative study, 565.

Psylla mali, see Apple sucker.

Psylla pyricola, see Pear psylla.

Pterophorus periscelidactylus, see Grape plume moth.

Ptinus tectus, biology and behavior, 95, 549.

Ptychogaster cubensis, wood-decaying fungus of southern oaks and waxmyrtle, 390.

Public administration, improving, Iowa 445.

Public assistance, rural, effect of defense program, 739.

Puccinia—

asparagi, notes, 385.

distincta, cause of English marigold rust, 243.

graminis tritici—see also Wheat stem rust.

physiologic specialization in South America, 71.

unusually virulent race in Peru, 688.

telocarpum n.comb. on *Ocimum adscendens*, 530.

schedonnardi, notes, Ariz. 805.

Puerto Rico Station report, 322, 755.

Puerto Rico University Station report, 323.

Pullet(s)—

and cockerels, comparative growth response to protein supplements, Wash. 404.

cost of production, Ariz. 869.

disease, blue comb, or "X" disease, isolation of filtrable virus from, 720.

from old and young breeders, viability, N.J. 360.

growth rate relation to sexual maturity, N.J. 403.

layers, White Leghorn, rations and feeding methods, Ohio 260.

laying, controlled feeding, 559.

laying, effect of ultraviolet irradiation, Ind. 698.

mineral metabolism, 409.

pastures for, Tenn. 404.

range for, restricted feeding with, Mass. 837.

Rhode Island Red, infected with paralysis or leukemia, growth rate, Mo. 99.

White Leghorn, winter egg production characteristics, relation to shank color, 260.

Pullorum-agglutinating chicken serums, electrophoretic study, 722.

Pullorum disease—see also *Salmonella pullorum*.

chick resistance to, effect of diet, Ill. 496.

control, commercially prepared antigen for, Ill. 564.

eradication, Mass. 858.

genetic resistance to, [N.Y.]Cornell 47.

in chicks, Idaho 709.

resistance, development in poultry, Ariz. 788.

resistance in poultry, inheritance and progeny testing, Ill. 496.

- Pullularia pullulans* injury to red pine, 245.
 Pulp and paper manufacture, microbiological control, advantages, 20.
 Pulse rate of Europeans, effect of tropical environment, 307.
 Pumpkin(s)—
 canning, improvement in type and quality, Iowa 220.
 disease, rare, 229.
 Pythium spp. on, Mo. 67.
 variety tests, P.R.U. 221.
 Purdue University notes, 160, 466.
 Purple scale control, Fla. 822.
Pyrausta nubilalis, see Corn borer, European.
 Pyrethrins—
 determination, Sell v. mercury reduction method for, 335.
 effect on rodents, 826.
 Pyrethrum—
 analysis, 335.
 insecticidal action on houseflies, effect of sesamin and related compounds, 830.
 Pyridine carboxylic and aminobenzoic acids, fungistatic properties, 532.
 Pyridoxin—see also Vitamin B₆.
 deficient diet and dermatitis, 457.
 determination, Scudl colorimetric method for, 762.
 requirement, possible sparing action of linoleic acid on, 745.
 specificity for growth of excised tomato roots, 488.
 Pyrimidine studies on older subjects, 314.
 Pyruvic acid in blood following glucose ingestion, 603.
 Pythiaceae, composition of hyphae, 340.
Pythium—
 arrhenomanes on cereals and grasses in northern Great Plains, 231.
 arrhenomanes, relation to milo disease, 812.
 debaryanum on alfalfa seedlings, Iowa 681.
 growth and thiamin, 351.
 spp. on fibrous-rooted begonia, pumpkin, etc., Mo. 67.
 Q fever, epidemiology, studies, 111.
 Quackgrass—
 control by cultivation, Wyo. 793.
 seed germination, 512.
 seed, identification, Wis. 505.
 Quail—
 bobwhite, foods and conservation farming, 545.
 bobwhite, tegmentum vasculosum in cochlea, development, 246.
 fall feeds, Pa. 546.
 management, Iowa 245.
 valley, studies, Calif. 694.
Quercus—
 host-parasite check-list revision, U.S.D.A. 877.
 hybridism, ecotypes, and peripheral race variants in, 82.
 Macrocarpa in Alabama 777.
 Quinine in bark, determination, standardization of methods, P.R. 617.
 Rabbit(s)—
 cereal grass juice for, Mo. 98.
 cottontail, nests and nestlings, 544.
 cottontail, studies, Iowa 245.
 digestible nutrients of feeds for, Pa. 546.
 forage requirements of range vegetation by, Ariz. 819.
 genetic linkage in, 496.
 hazard to coniferous plantations, Mich. 245.
 heat production, effect of previous adaptation to temperatures, 407.
 juvenile, initiation and maintenance of pregnancy in, 209.
 ovum in vitro, nutrition of, 789.
 pathologic tissue changes produced by sulfathiazole and sulfathiazoline, 564.
 repellents, Ind. 694.
 snowshoe, reports of observers, 246.
 tick, parasite of, 553.
 Rabbitbrush, rubber from, Nev. 227, Utah 676.
 Rabies—
 diagnosis, probability of error in, 710.
 vaccine for prophylactic immunization of dogs, 858.
 vaccines, experimental studies, 274.
 Raccoon(s)—
 ecology and management, Iowa 245.
 use of rock exposures for den and escape cover, 391.
 Radiation—see also Solar radiation.
 intensity and illumination climate, 181.
 ultraviolet solar and sky, spectral range, use, 181.
 Radish—
 boron deficiency in, N.J. 371.
 growth and development, effect of boron, 78.
 growth, effect of vitamins, 39.
 Ragweed borer parasite, Va. 824.
Raillietina—
 cesticillus in fowl, removal by short periods of starvation, 571.
 (*Raillietina*) *bakeri* n.sp. in squirrels, 419.
 Rainfall—see also Precipitation.
 effect on movement of soil nitrogen, Ga. 770.
 in India, long-range forecasts, 22.
 relation to drainage and other factors, 21.
 runoff, year's record at State College, Mich. 182.
 Raisins, yield, composition, and quality, relation to maturity of grapes, Calif. 839.
 Ram(s)—
 breeding capacity, Mo. 47.
 semen storage, Mo. 47.
 spermatozoa staining method, 500.
 sterile, lack of response to ascorbic acid therapy, Idaho 697.
 Ramie fertilizer tests, Fla. 791.
 Ramie production tests, Fla. 791.
 Ranch(es)—
 mixed, financial and physical data, N.Mex. 435.

Ranch(es)—Continued.

organization and management in granite area, Calif. 732.

organization and operation, Nev. 130.

Randia to *Rhododendron*, host-parasite check-list revision, U.S.D.A. 377.

Randu tree podborer, life history and control, 402.

Range(s)—

carrying capacity, improved method of determining, N.Mex. 403.

desert grassland, relation to climatic and grazing conditions, Ariz. 791.

forage, estimating value for grazing, Nev. 795.

forage production, relation to time and frequency of harvesting, Wyo. 794.

grasses, *see* Grass(es).

land conservation and use problems, 98.

livestock, phosphorus and calcium supplements for, N.Mex. 100.

of Nevada, Bronco grass on, Nev. 662.

of New Mexico, reseeded practices for, N.Mex. 507.

of South Dakota, carrying capacity, S.Dak. 554.

plants, poisonous, *see* Plant(s), poisonous, Cattle poisoning, and specific plants.

plants under cultivation, economic value, Ariz. 791.

restoration studies, N.Mex. 366.

rodents and wildlife on, interrelations, Calif. 694.

San Joaquin Experimental, description, Calif. 755.

San Joaquin Experimental, program, studies and experiments, Calif. 601.

soils, overgrazed v. protected, 487.

***Ranunculus*—**

in North America, geographical distribution centers, 32.

relation to North American floras, 777.

Raspberry (ies)—

and apple juice, demonstration sale, 17.

anthracnose, new spray for, U.S.D.A. 377.

black, anthracnose-resistant, breeding, Iowa 220.

black, breeding, Ill. 516.

breeding for hardiness and disease resistance, Wash. 372.

breeding improved varieties, Tenn. 371.

canes, method of determining when killed by extremes of temperature, 513.

composition, Tenn. 327.

culture, diseases, and insects, N.Y.State 520.

fruitworm, studies, U.S.D.A. 88.

insects, life history and control, Wash. 92.

leaf spot, U.S.D.A. 805.

mulching experiments, Ky. 800.

necrotic "fern-leaf" mosaic, 241.

plantations, organic matter for, N.J. 371.

Raspberry (ies)—Continued.

preserved by frozen-pack method, ascorbic acid in, 152.

resistance to low-temperature injury, Wis. 513.

sawfly, notes, Del. 245.

varieties, N.Mex. 371.

vitamin C in, 605.

winter hardiness in, nature, Mass. 800.

Rat(s)—*see also* Rodent(s).

albino, egg, ovary, and oviduct in, relations, 654.

and pigeons, relation of protein and purine metabolism in, 698.

castrated, long bones of, 50.

choline-deficient, biochemical defect in, 889.

control, using baits in, 544.

copper-induced pseudopregnancy in, 362.

cyclical activity, apparatus for recording, 498.

diurnal metabolic and activity rhythms, Mo. 103.

fasted hypophysectomized, blood sugar and glycogen stores, effect of thyroxin, 503.

graying, failure to cure or prevent with *p*-aminobenzoic acid, 751.

hairlessness in, completion of studies, Ill. 496.

hemoglobin content, relation to meat scrap or fresh beef, N.J. 403.

hypophysectomized—

effect of follicle-stimulating and interstitial cell-stimulating hormone injections, 501.

effect of purified pituitary preparations on, 301.

response to growth hormone, 404.

immature female, potency of stilboestrol in, 502.

"light oestrous" response, hereditary factors conditioning, 655.

mite, tropical, Del. 245.

nutrition, pantothenic acid in, 893.

on meat diets, growth, reproduction, lactation, etc., of, Iowa 303.

parturition data and subsequent oestrous, and ovulation, 499.

poisoning, studies, 394.

preference for inbred and hybrid corn, Ill. 554.

rate of breeding, effect on ability to reproduce, [N.Y.]Cornell 47.

reproduction and lactation, effect of simplified diet, 98.

rib, costochondral junction of, effect of growth hormone injections, 789.

spectacle-eyed—

and biotin deficiency, 599.

and inositol, 316.

stub, developmental abnormalities and spontaneous diseases in, 497.

survey, ecological, Ind. 694.

taillessness in, heredity and accident as factors, 361.

Rat(s)—Continued.

tibia and rib ossification, effect of crystalline oestrin implants, 362.
treated prepuberally with oestrogen, modification of reproductive capacity in, 655.

vitamin requirements, effect of exercise, Pa. 589.

Rayon—

fabrics, shrinkage determination, new methods, 320.

taffetas, wear tests, 320.

Recurvata milleri, see Lodgepole needle miner.

Red berry mite, studies, U.S.D.A. 88.

Red mite, European—

control, oil sprays for, Mass. 820.
notes, Conn. [New Haven] 822.

Red scale, California—

control, improvements in, U.S.D.A. 88.
on citrus, mortality, cause, 548.
out-of-doors in Berkeley, 549.
use of kerosene-rotenone spray for, problems, 549.

Red scale, failure to control with hydrocyanic acid, cause, 2.

Red spider—

control in greenhouse, U.S.D.A. 88.
control with insecticides, 395.
on carnations in greenhouses, control, 2.
on greenhouse plants, control, Mass. 820.
spray mix, rotenone for, Pa. 546.

Red squill—

fortification with extract of red squill, 544.

research, Mass. 820.

Red canary grass, fertilizer needs, Wis. 504.

Refrigeration—see also Locker plants, farm, 278.

Relief, agricultural, measures and raising of farm prices, U.S.D.A. 293.

Relief, rural administration and financing in New York, [N.Y.] Cornell 130.

Religion and assimilation of Dutch in Michigan, Mich. 301.

Reproduction in livestock, role of endocrine secretions and nutrients in, 258.

Reproductive capacity of rats treated prepuberally with oestrogen, modification, 655.

Resazurin-rennet test, studies, 106.

Research—

Laboratory, Western Regional, Utah 323.

procedures, 322.

Respiration—

and mitotic periodicity in plants, correlation, 81.

in plant cells, relation to accumulation of chlorides by, 201.

measurement in plants, relation to passage of air through, 492.

of *Blotaea*, 202.

rate of leaves, metabolism of carbohydrate, protein, and organic acids in, relations, 201.

Respiration—Continued.

total, of yeast, separation of an "activity" metabolism from, 201.

Retioultermes tibialis in cottonseed hulls, 247.

Revenue curves, total, shape of, 583.

Rhagoletis pomonella, see Apple maggot and Blueberry maggot.

Rhinotrichum griseo roseum n.sp., description, 238.

Rhipicephalus—

glabroscutatum n.sp., description, 851.

sanguineus, see Dog tick, brown.

Rhizobium—

leguminosarum, hydrogenase in, 195.

spp. and legumes, 350.

spp., biotin as growth factor, 352.

strains, limited numbers of nodules produced on legumes by, 36.

trifolii, oxidation and assimilation of glucose by, 777.

trifolii strains, relative efficiency, effect of soil fertility, 488.

Rhizoctonia—

bataticola on potatoes in Illinois, U.S.D.A. 377.

diseases of potato and vegetable crops, Fla. 806.

on potato, control by seed treatment, Me. 228.

removal from potato tubers by chlorinated lime treatment, 75.

solani from potatoes, sclerotial isolates, temperature relations, 685.

solani from subterranean clover seed, 683.

solani isolates from wheat, growth in soil and parasitic action, 381.

solani, on corn, 234.

solani, stem-end tuber rot due to, 685.

Rhizopus *sinicus* growth, factors affecting, 778.

Rhode Island College notes, 468, 612.

Rhode Island Station notes, 468, 612.

Rhododendron (s)—

culture, N.J. 371.

top blight, U.S.D.A. 805.

Rhodotypos to *Rondeletia*, host parasite check-list revision, U.S.D.A. 527.

Rhopobota naevana, see Fireworm, black-headed.

Rhubarb—

breeding, Ind. 668, Pa. 513.

vitamin C in, Wash. 447.

Rhyacionia buoliana, see Pine shoot moth, European.

Riboflavin—

analysis of cereals, 621.

and thiamin in food products, combined determination, 10.

and thiamin metabolism, 698.

annotated bibliography supplement, 151.

bacterial growth activity, effect of factor in blood, 151.

deficient chicks, metabolism and food utilization, 839.

deficient eggs, effect on embryonic development, 790.

Riboflavin—Continued.

- deficient rats, succinoxidase system in, 894.
- deficiency, effect on fatal pneumococcal infection in mice, 110.
- deficiency in man, excretion test as measure, 750.
- deficiency in rat, pathology, 314.
- deficiency, xanthine oxidase content of rat liver in, 457.
- destruction by light, 622.
- determination, comparison of methods, 10.
- determination, modified microbiological method, 11.
- effect on curled-toe paralysis and growth in chicks, 262.
- for poultry, dried whey as source, Idaho 697.
- in fish products, 151.
- in green snap beans, effect of freezing, canning, and dehydration, 891.
- in isolated roots, 351.
- in rye and its milled products, 146.
- in tissues of adults at liberal levels of intake, 456.
- in urine and other biological fluids, fluorometric determination, 621.
- in wheat and corn, 148.
- rat growth assay method for, 749.
- reduction by streptococci, [N.Y.]Cornell 33.

Rice—

- and byproducts, nutritive studies, Ark. 803.
- blast in Arkansas, U.S.D.A. 377.
- diseases, 67, 71.
- dry and wet cultivated, protein and mineral constituents, nutritive value, 883.
- insects, 394, U.S.D.A. 91.
- panicles, adventitious roots on, 510.
- plants affected by *Gibberella fujikuroi*, pathological anatomy, 813.
- plants, growth, effect of vitamin B₁, 195.
- precooked dry, new canned product, 139.
- production on poor lowland soils, Mo. 214.
- quality in, 883.
- respiration, fermentation, and growth in, effect of oxygen, 202.
- root rot studies, 232.
- rough, marketing, La. 869.
- stalk borer, U.S.D.A. 91.
- stinkbug, notes, U.S.D.A. 91.
- varieties, Mo. 214.
- varieties, protein and mineral constituents, nutritive value, 883.

Ricinus communis, traumatic acid and mitosis in, 31.

Rickettsia burnetti, studies, 111.

Robillarda agrostidis, notes, 72.

Rocky Mountain spotted fever increase, importance of rodent trapping, Del. 245.

Rodent(s)—see also Mice and Rat(s).

and wildlife on range, interrelations, Calif. 694.

control, Ind. 694.

Rodent(s)—Continued.

- control, engineering aspects, 431.
- effects of pyrethrins on, 826.
- pests in New York, economics and biology, [N.Y.]Cornell 85.
- pests of Iowa, control, Iowa 820.
- preference for different forest species, Pa. 524.
- trapping, importance, due to increase of Rocky Mountain spotted fever, Del. 245.

Romalea microptera, see Grasshopper, eastern lubber.

Root(s)—

- flora and fauna associated with, methods of observing, 637.
- growth, formative effects of carbohydrates on, 354.
- knot control, Fla. 806.
- knot nematode—
 - control, Miss. 238.
 - control, chloropicrin and ethylene dichloride for, 819.
 - cultural measures for control, 238.
 - larvae, transient feeding, 819.
 - of potato, Nev. 236.
 - studies, S.C. 378.
- knot prevention and control, Miss. 381.
- meristems, cell growth and division in, 31, 785.
- nodule bacteria, oxidation and assimilation of glucose by, 777.
- of *Vicia faba*, relation between xylem thickenings and elongation, 358.
- systems, new, growing by soil banking, 531.
- tips, isolated, riboflavin in, 351.
- tips under varying light conditions, periodicity and rhythmicity of mitotic phases, U.S.D.A. 485.

Rootstock tests, Ariz. 799.

Rosa, host-parasite check-list revision, U.S. D.A. 527.

Rose(s)—

- black spot control, 692.
- black spot, varietal resistance, tests, U.S.D.A. 680.
- breeding, S.Dak. 513.
- chafer control, Mich. 831.
- Crimson Rambler and its progenies, 523.
- crown gall, effect of crop rotation on, 244.
- culture and fertilization, Pa. 513.
- diploid and polyploid, crossing relations, 47.
- effect of trenching and soil mixtures, 676.
- greenhouse, effect of sprays on apparent photosynthetic rate, 226.
- greenhouse, fertilization, Ill. 523.
- greenhouse, method of watering, [N.Y.] Cornell 64.
- greenhouse, photosynthesis, effect of spray materials, Ohio 203.
- growth, effect of soil temperature, Mass. 775.

Rose(s)—Continued.

- hips, wild, vitamin C in, 605.
- mosaic, effect of temperature on symptom expression, 244.
- organic matter sources for, [N.Y.]Cornell 64.
- peat moss as soil amendment, 226.
- planting and mulching methods, [N.Y.] Cornell 64.

- root knot, effect of crop rotation on, 244.
- soil aeration for, [N.Y.]Cornell 64.
- species of North America, distribution, 676.
- stocks, breeding and testing, Iowa 220.
- testing for heat resistance and use as cut flowers, Iowa 220.
- understock resistant to root knot nematode, U.S.D.A. 377.
- winter injury, causes and protection, 543.

Rosmarinus to *Rubus*, host-parasite check-list revision, U.S.D.A. 680.

- Rotation of crops, Fla. 769, Mo. 22, N.Y.State 801, Va. 793.
- effects of limestone and fertilizers in, N.C. 344.
- ordinary, grazed, manured, and fertilized, Wyo. 793.

Rotenone—

- color reaction, adaptation to photoelectric colorimeter, 397.
- containing plants, evaluation problem, 826.
- crops, physiology of, P.R. 646.
- dust in pea weevil control, reduced per acre poundage possible, Idaho 694.
- kerosene spray, caution urged in use, 547.
- melting point, effect of soft glass on, 179.
- producing plants, culture and handling, P.R. 608.
- toxicity, 396.

Roughages, vitamin A and D content, factors affecting, S.Dak. 563.

Royal jelly of Florida, composition and nutritive value, Fla. 880.

Rozella—

- achlyae* n.sp., description, 808.
- cladochytrii* host range, 230.
- endochytrii* n.sp., notes, 230.
- rhizophyctii* n.sp., notes, 230.
- synopsis, 230.

Rozellopsis—

- new genus proposed, 230.
- synopsis, 230.

Rubber—

- from rabbitbrush, Nev. 227.
- from western desert plants, Utah 676.
- growing, pests and diseases in, 390.
- thread, synthetic development, 753.

Rudbeckia bicolor, relation of photoperiodic induction to photoperiodic inhibition in, Mo. 32.

Rumen—

- absorption from, 698.
- bovine, motility, effect of drugs on, 853.

Ruminants—

- digestibility studies, 257.
- H and CO₂ production in digestive tract, relation to respiratory exchange, Mo. 103.

Runoff—

- and erosion, effect of plant cover, Wash. 343.
- and erosion, measuring, tilt buckets for, 861.
- cycle, outline, 631.
- divisors, small-fraction, calibration, Tenn. 342.
- from small watersheds, hydrologic studies and measurement, Ind. 725.
- infiltration in relation to, 632.
- measurements, equipment for, 120.
- studies, Idaho 724.

Rural—

- church, relation to other social organizations and agencies, 878.
- Electrification Administration, report, U.S.D.A. 278.
- labor, *see* Agricultural labor.
- life, effect of tenure status, S.Dak. 737.
- operations and credit in State, Mass. 866.
- organizations, factors determining effectiveness, Iowa 300.
- population of Virginia, income and living standards, 164.
- schools, *see* School(s), rural.
- youth problems, Minn. 445.

Rust—

- earliest known epiphytotic of in Iowa, 191, 228.
- early leaf, development in eastern Nebraska, U.S.D.A. 680.
- fungi taxonomy, Ind. 679.
- mites on citrus, 554.

Rye—

- adaptation to lowland soils and production methods, Mo. 213.
- and milled products, vitamins in, 146.
- and winter and spring wheat varieties, comparison, Wis. 505.
- breeding, S.Dak. 504, Wash. 367.
- for winter pasture of sows, Ill. 554.
- glandular epithelium of scutellum, cytoplasmic inclusions in, 784.
- hybrids, inheritance of disease resistance, Wash. 367.
- immature, freezable water and oxygen respiration in, 492.
- varieties, Mo. 214.
- variety tests, S.C. 367, Wash. 367, Wyo. 793.
- yields and production costs, Mo. 53.

Ryegrass—

- as weed and control, N.J. 366.
- perennial, new alkaloid from, isolation, 492.

Sabal to *Salix*, host-parasite check-list revision, U.S.D.A. 681.

Saccharomyces cerevisiae strains, effect of vitamins, 644.

- Saccharum spontaneum* variants, comparative analysis of vegetative characteristics, U.S.D.A. 651.
- Saddleback caterpillar, notes, Del. 245.
- Safflower—
dieback in Texas, U.S.D.A. 680.
fungus disease, little known and rare, 229.
tests, N.Mex. 360.
varieties, N.Mex. 371.
- Saissetia*—
nigra, shipment to California, P.R. 695.
oleae, see Black scale.
- Saliva, human fluorine in, 890.
- Salix*, host-parasite check-list revision, U.S.D.A. 805.
- Salmonella*—
breedney infection in birds, 858.
enteritidis, food infected with, housefly as vector of infection, 553.
genus, beta phases and undescribed types, 419.
in lymph glands of hogs, 856.
infection and carrier state in mice, effect of sulfanilylguanidine, 712.
infections of pigeons in Dutch East Indies, 427.
new type with undescribed flagellar antigens, 712.
- pullorum*—see also Pullorum disease.
in fowl, genetic resistance to, relation to body temperature, [N.Y.] Cornell 722.
species, frequency of occurrence, 712.
spp., nutritional requirements, comparison, 111.
types in silver foxes, 118.
types, isolation of, Mass. 858.
typhi, stability of Vi antigen of, 420.
typhimurium cause of death of week-old wood ducks, 277.
typhimurium infection in chinchillas, bacterin treatment, 118.
typhimurium infection in muskrats, 420.
- Salsify, leaf spot disease, 79.
- Salt, absorption in farm-cured ham, hastening, Pa. 836.
- Samanea* to *Sassafras*, host-parasite check-list revision, U.S.D.A. 805.
- San Jose scale—
in cranberry bogs, dormant sprays for, Wash. 394.
scale studies, Ill. 546.
- Sand flies, studies, U.S.D.A. 89.
- Sandy—
loam, Collington, organic matter in, 25.
soils, need of phosphate and potash, Wis. 483.
soils of central Florida, adsorption and fixation of copper in, 190.
soils, suitability of summer cover crops, Fla. 799.
- Sanninidea celtiosa*, see Peachtree borer.
- Saperda tridentata*, see Elm borer.
- Sapodilla* rust in Florida, U.S.D.A. 680.
- Sarcophaga*—
austrana, new parasite from mantids, description, 255.
bullata, cause of intestinal myiasis, 553.
- Sardine oil as vitamin D supplement for poultry, Idaho 697.
- Sauerkraut—
canned, quality and chemical composition, relation, 18.
manufacture, common errors in, 18.
pink, cause, 33.
processing, 19.
vitamin C in, and changes during storage, 459.
- Sausage, starch determination in, 330.
- Saw, small electrically operated cross-cut, U.S.D.A. 124.
- Sawdust burners, rating and care, 281.
- Scab gnats, relation to potato tuber defects, [N.Y.] Cornell 90.
- Scabies, effects of drugs on, histological comparison, 111.
- Scale insects—see also Black scale, Purple scale, and Red scale.
on bamboo, control, P.R. 695.
on citrus, control, Fla. 822.
on citrus, control problems, 549.
sprays for, Wash. 393.
studies, Ariz. 819.
- Scaptiscus*—
acetus, see Cricket, southern mole.
vicinus, see Changa.
- Schistosomes, new, from birds of Wisconsin and Michigan, 86.
- School(s)—
administration in Pope County, Ill. 583.
districts, public finance situation in, with and without oil development, Okla. 730.
rural elementary, planning lunches for, 306.
secondary, biology teaching in, 136.
- Scientific and technical periodical publications, catalog, 755.
- Scientists face the world of 1942, 609.
- Scirtothrips citri*, see Citrus thrips.
- Sclerospora*—
noblei, conidial phase, 75
philippinensis, notes, 234.
sacchari mildew of sugarcane and other grasses, 236.
- Sclerotinia*—
fruticola cankers on peach, [N.Y.] Cornell 68.
fruticola on peach, apothecia of, 816.
laxa in stone fruits, arsenite sprays for, 540.
on Great Northern beans, U.S.D.A. 377.
sclerotium growth, effect of chemicals, Ariz. 805.
sclerotium on poppy in Oregon, U.S. D.A. 805.
stem rot on *Oenothera cyanus* and *Delphinium ajacis*, Mo. 67.

Sclerotium—

bataticola, cause of damping-off in seedling conifers, 83.

bataticola from subterranean clover seed, 683.

rolfsii, cultural characters and mechanism of parasitism, 529.

rolfsii growth and parasitism and host relations, Fla. 806.

rolfsii, studies, 529.

Scolytidae, food plant relations in Hawaii, 546.

Scolytus—

multistriatus, see Elm bark beetle, smaller European.

sulcatus on apple trees, relation to Dutch elm disease control program, 550.

Scours in dairy calves, 272.

Screwbean, nomenclature, Ariz. 776.

Screwworm(s)—

larvae, acquired resistance to phenothiazine by, 255.

larvicides and wound protectors against, 255.

studies, U.S.D.A. 89.

Scurfy scale control with insecticides, 395.

Scurvy—

development, effect of intermittent consumption of vitamin C on, 895.

infantile, serum phosphatase in, 606.

Scymnus creperus predator on woolly elm aphid, 247.

Seborrhea and the B vitamins, 600.

Seed(s)—

absorption of water by, factors affecting, 32.

agricultural, examination, Me. 219.

control field problems, 513.

disinfection, loss of vitality during storage resulting from, 231.

dormancy in, 32.

dormant, approximate germination tests, 512.

drier, infrared electric lamps for, 125.

flats, watering, use of wicks for, [N.Y.] Cornell 64.

germination, effects of mercury vapor, 648.

germination media, evaluation, 512.

germination tests, homogeneity in, 512.

inspection, Ind. 370, Ky. 370, Mass. 370.

law, new, of Iowa, 512.

production, relation to zinc, 646.

quality vital in all-out production, Colo. 798.

testing in home and school, U.S.D.A. 370.

testing, need of, as part of all-out food production effort, Colo. 667.

tests for 1941, results, N.H. 55.

weak, cause of crop failures, N.Y.State 798.

weed, see Weed seeds.

weight, relation to vegetative growth, differentiation, and yield in plants, 198.

X-rayed, germination, relation to catalase ratio, 195.

Seedbeds, methods of preparing for different crops, Wyo. 793.

Seed-corn maggot, biology and control, [N.Y.] Cornell 90.

Seedlings, culture in sunlight under controlled temperature conditions, 649.

Setulus mites on tobacco moth, 823.

Selection indexes, constructing to make maximum progress, 209.

Selective Service physical standards and health of school children, 311.

Selenate absorption by colloidal ferric hydroxide, 329.

Seleniferous areas, locating, use of indicator plants in, 37.

Selenite selenium absorption by colloidal ferric hydroxide, 329.

Selenium—

availability to plants, methods for determining, 613.

in toxic wheat, form in which found, 200.

indicator species of *Astragalus*, identification, 711.

poisoning, 37.

poisoning in livestock and man, 98.

poisoning prevention, arsenic for, S.Dak. 564.

poisonous to livestock, Wyo. 851.

rations for laying hens, linseed meal as supplement, S.Dak. 554.

Selenium-cystine, decomposition in electro-dialysis and acid hydrolysis, 332.

Semen—

bovine, fecundity, effect of diluters and storage, 209.

collections, first and second, from dairy bulls, comparison, 209.

production in fowl, relation to light, [N.Y.] Cornell 47.

ram, concentration and metabolism of sugar in, Mo. 210.

stored, preservation, [N.Y.] Cornell 47.

Senecio—

alkaloids of South Africa, 851.

poisonous to livestock, Wyo. 851.

Sensitization studies, 272.

Sepsis cynipsea, nematode parasite of, morphology, 302.

Septic tank dimensions, studies, Ill. 573.

Septoria—

apii gravcolentis in Argentina, 538.

leaf blight of chrysanthemums, 243.

secalis stipae n.var., notes, 72.

spores, structure and germination, 538.

Sequoia bark fibers, 753.

Serratia marcescens—

as cause of pink sauerkraut, 38.

lethal effect of drier rolls on, 348.

Serum(s)—

human and animal, surveys for *Mickettsia burnetti* agglutinins, 111.

proteins, genic effects, 49.

Sesame—

fertile tetraploids induced by colchicine, 44.

Sesame—Continued.

oil, studies, U.S.D.A. 5.

production tests, P.R.U. 213.

Sesamin, effect on insecticidal action of pyrethrum on housefly, 830.**Sesamum orientale**, sterility in, cytological study, 495.**Sewage—see also Sludge.**

oxidation of carbonaceous and nitrogenous materials in, N.J. 428.

sludge incinerator ash, use for commercial purposes, N.J. 428.

sludge, plant nutrients in, effect of processes of treatment, N.J. 428.

stale, odors produced by, control, N.J. 428.

treatment, grease problem in, 726.

treatment processes, sources of odor in, N.J. 428.

Sex hormones, see **Hormones**.**Sexual—**

maturity factor in plant juices, 654.

maturity in female rat, attainment, 654.

periodicity, exteroceptive factors in, 498.

Shallot pink root, U.S.D.A. 528.**Shark-liver oil—**

feeding, effect on milk production and blood vitamin A, 410.

vitamin D in, for poultry, Fla. 833.

Sheep—see also Ewe(s) and Lamb(s).

artificial insemination in, Mo. 47.

bighorn, source of parasite infection of domestic sheep, Wyo. 273.

blood phosphorus and phosphorus requirements, Idaho 697.

breed crosses, comparison for early lamb production, Pa. 554.

chromosome counts, Mo. 47.

cobalt deficiency in, development, 716.

copper in blood of, 115.

crossbreeds, wool and lamb characters, Wyo. 788.

different cuttings and baled alfalfa hay for, N.Mex. 403.

dipping tank, portable, Mo. 120.

drives, eastward, from California and Oregon, 556.

dwarfism in, inheritance, 209.

fertility at high altitudes in Peru, 209.

fiber coats for, Wyo. 834.

foot rot, cause, epidemiology, and control, 273.

genetic studies, Wyo. 788.

grazing Pingue with, N.Mex. 403.

helminth parasites of, 716.

migration in Intermountain Region, U.S.D.A. 131.

multiple pregnancies experimentally produced, fate of, 209.

Navajo, improvement, evaluation of fleece yield in, 208.

of various breeds and crossbreeds, fleece and mutton production, Fla. 788.

of various breeds, lamb and wool production, N.Mex. 403.

on ranches, financial and physical data, N.Mex. 435.

Sheep—Continued.**parasite(s)—**

internal, Mo. 717.

larvae in feces, effect of phenothiazine-salt mixtures on, 570.

on irrigated pastures, Oreg. 856.

phenothiazine failure to control, 116.

parasitic diseases, control measures, tests, 570.

pining in, effect of cobalt-rich fertilizers, 570.

poisoning from cloak fern, Tex. 565.

poisoning from lichen, control, 162.

production, rotational grazing and internal parasites in, Fla. 833.

range, weanling and yearling fleece characters in, relation, 97.

rations, effect of added glucose on digestibility of protein and of fiber, 406.

removal of gastrointestinal parasites with phenothiazine, 271.

rock phosphate as mineral supplement for, 97.

shipped into Minnesota, Minn. 732.

stomach, nodular, and tapeworms, pathology and comparative damage, Mo. 108.

treated with phenothiazine, blood picture, 856.

types and breeding for southern Illinois lamb production, Ill. 496.

with no tails, development, S.Dak. 554.

wool yield calculations for breeds, 556.

worm-free, effect of phenothiazine on weight, 423.

worm parasites of digestive tract, control. [N.Y.] Cornell 109.

Shelterbelt(s)—

effect on air movement, Ind. 677.

trees, variety tests, Wyo. 801.

Shortenings—

new, water tolerance, relation to sweeter cakes at higher altitudes, Colo. 304.

nutritive properties, 440.

Shrimp meal as protein source for chicks, Miss. 702.**Shrubby planting, pruning recommended for, Miss. 221.****Shrubs—**

and weeds effect on weight gains of cattle grazing pastures, Colo. 258.

desirable varieties, N.J. 371.

growth in shelterbelt, effect of fertilizer and culture, S.Dak. 513.

in California deserts, dependence of annual plants on, 353.

ornamental, testing, Wash. 372.

toadstool root rot of, 542.

Sidine stimulea*, see Saddleback caterpillar.*Silage(s)—**

alfalfa-bromegrass v. corn, for dairy cows, Ind. 704.

alfalfa, preserved with molasses, phosphoric acid, salt, and inoculation, fermentation of, 413.

alfalfa, v. Atlas sorgo silage for dairy cows, Ariz. 841.

Silage(s)—Continued.

- and hay, feeding value, Vt. 563.
- corn, harvesting, processing, and storing, methods and equipment, Iowa 284.
- corn, yields and production costs, Mo. 53.
- evaluation of quality in, role of pH determination, 404.
- for dairy cattle, comparison, N.J. 410, Tenn. 411.
- grass and corn, effect on milk flavors, Mass. 842.
- grass and corn, need for separate silo reinforcing schedules, N.J. 428.
- grass and legume, preparation and use, with molasses or phosphoric acid, N.J. 410.
- grass, carotenoids of, 702.
- grass, conservation of nutrients in, Vt. 848.
- grass, digestibility by dairy cows, 843.
- grass, feeding, N.J. 704.
- grass, hazardous horse feed, 857.
- grass, in wartime, Mo. 704.
- grass, nutritive value, Tenn. 404.
- grass, preservation; Wis. 555.
- grass, preserved with phosphoric acid or molasses, palatability, [N.Y.]Cornell 104.
- grass v. corn, for cows and helpers, Vt. 563.
- grass v. hay for heifers, Vt. 563.
- hay crop, making and feeding, Minn. 704.
- lawn clipping, for dairy goat production, N.J. 403.
- lawn clipping, for growing chicks, N.J. 403.
- legume, experiments, Tenn. 428.
- legume v. corn v. legume hay for fattening calves, Mich. 258.
- molasses- and phosphoric acid-alfalfa, value for dairy cows, 410.
- molasses-legume-grass v. corn, for milk production [N.Y.]Cornell 104.
- mung bean, precautions for making, Okla. 704.
- photochemical reactions in, 158.
- potatoes, corn, and sorghum for, Idaho 697.
- sorghum, value for dairy herd, Miss. 704.
- soybean-sorghum v. sorghum alone, Miss. 405.
- stack, losses and nutritive value, effect of type of construction, Wash. 428.
- sugarcane, compared to shocked cane or pasture, Fla. 833.
- types for milking cows, S.Dak. 563.
- without molasses, crops suitable for, N.J. 563.

Silica—

- gel, adaptability as culture medium, 349.
- in acid-insoluble silicates, rapid determination, 382.

Silicates, iron determination in, 384.**Silo(s)**—

- capacity for grass v. corn silage, N.J. 428.
- filling with corn and sorghum, Mo. 834.
- leakage, waste from and remedy, N.J. 428.

Silo(s)—Continued.

- pressure studies, N.J. 428.
- staves, dry tamped, durability, 121.
- types, alternative, to meet war demand for steel, 580.

Silver—

- absorption and excretion by man, 748.
- fungicides, mechanism of action, 380.
- Silvius* species west of Mississippi River, 402.
- Simulium nigroparvum*, transmission of blood protozoan of turkeys by, 724.
- Sipha flava*, predator of, shipment to Louisiana, P.R. 695.
- Siphona irritans*, see Hornfly.
- Siphonaptera of North America, index to literature, 553.

Sires—see also Bull(s).

- proved in dairy herd improvement association, list, U.S.D.A. 846.
- proved, use in Holstein and Jersey herds, results, Idaho 703.

Sitona cylindricollis, notes, N.Dak. 832.**Skim milk powder** as substitute for skim milk in raising calves, Wyo. 842.**Skin grafts** deprived of source of melanophores, post-hatching migration of pigment cells into, 655.**Skin, oxygen consumption during hair cycle in rat and after adrenalectomy, 654.****Skunk**—

- spotted, trapping technique, Iowa 245.
- winter dens, ecological study, 545.

Slides and tissues, convenient washing devices for, 628.**Sloe, vitamin C in, 605.****Sludge, activated**—see also Sewage.

- control of bulking, effect of chlorine, N.J. 428.
- operation of plant, better control for, N.J. 428.

Slug(s)—

- baiting with metaldehyde mixed with various substances, 820.
- control, 391, U.S.D.A. 391.
- gray field, and its environment, 820.

Snails, control, U.S.D.A. 391.**Snakeroot, white, cause of milk sickness, 852.****Smut fungi, new species, 381.****Snapdragon(s)**—

- allotetraploids and autotetraploids, sterility differences, 46.
- breeding, Pa. 513.
- breeding for varietal improvement and disease resistance, Mass. 800.
- rust, 818.
- virosislike injury due to peach aphid, 94.

Sneezeweed, western, source of serious loss of sheep on high-altitude ranges, Colo. 855.**Snow melting characteristics and contribution to runoff, 632.****Snow surveys, 22.****Snowmobile, Utah, description, Utah 727.****Social**—

- change in South Dakota, basic trends, S.Dak. 444.
- conflicts and agricultural programs, 588.

Social—Continued.

sciences, rural, graduate students in, problems, 583.

sciences, rural, personnel training, 583.

Society—

American rural, role of village in, 738.

and conservation, 582.

rural, role in production of workers and soldiers, 738.

Sociological research in farm family living, 587.

Sociology, rural, studies, Pa. 586.

Sod, establishment on subsoil, N.J. 366.

Sod crops, producing, costs and practices in, Ind. 729.

Sodium—

azide, selective bacteriostatic effect of, 192.

chlorate mixtures, properties and herbicidal action, Iowa 213.

cyanide, effect on soil processes, N.J. 342.

determination, 172.

importance for plant nutrition, 29.

pentachlorophenate, toxic effects on water hyacinth, 354.

Soil(s)—

adapted to pasture, availability of calcium and phosphorus of colloidal phosphate applied to, Fla. 769.

adsorption of barium and hydroxyl ions by, relation to pH, 642.

aeration, conditions affecting, Miss. 27.

aggregates, effect of micro-organisms, 28.

aggregates, physicochemical aspects, 24.

aggrigant, studies, Me. 183.

air capacity, measuring, 161.

air, effect on plants, Miss. 27.

alkali, *see* Alkali.

American, auxins in, 344.

analysis, rapid chemical methods, 174.

and cropping systems, microbiological action in, interrelation, Fla. 769.

and field crop management, [N.Y.] Cornell 483.

and lime, testing, Iowa 183.

and plant relations, Fla. 760.

and related materials, complete and partial analysis, methods, Fla. 760.

and water conservation, Fla. 768.

bacteria producing bactericidal agents, isolation, 192.

bacteria to solve shortage of indicator litmus, N.Y. State 773.

bacterial activity, effect of different soil treatments, Mo. 22.

bacteriostatic and bactericidal substances in, 486.

base exchange capacity determination, 173.

base exchange in, 186.

capillary tension and moisture in, relation to capillary conductivity, Iowa 183.

characteristics affecting plant growth and composition, determination, 478.

Soil(s)—Continued.

chemistry and Liebig, 616.

classification, genetic, relation to properties of soil groups, 23.

clods, saturated and dry, volume change and pore space, 185.

colloids, *see* Colloids.

Conservation and Domestic Allotment Act, amended, U.S.D.A. 437.

conservation—

and increased production by farmers' cooperation, U.S.D.A. 639.

benefits, evaluation, needed developments in, 582.

benefits, physical evaluation, problems, 582.

by manure and cover crops, N.J. 342.

economic and social aspects, bibliography, U.S.D.A. 300.

folders for farmers and ranchers, U.S.D.A. 639.

in area approaching a worn-out condition, 187.

new landmarks, U.S.D.A. 26.

practices in Oklahoma, 187.

practices recommended in Texas, 187.

program too complicated for average New Jersey farm, N.J. 342.

program too complicated for average New Jersey farm, correction, N.J. 769.

programs for individual farms, Iowa 283.

publications, bibliography, Okla. 344.

relation to varieties and use of agricultural machinery, 430.

research on wind-blown soils, Mass. 769.

with organic matter, S.C. 342.

with stubble mulch, 122.

content of runoff and soil moisture, determination, Tenn. 342.

correlations, Fla. 769.

cropping and treatment, value as shown by Morrow plats, Ill. 482.

cultivated v. unbroken, loss of fertility of, Pa. 482.

defense in Oklahoma, bibliography, Okla. 344.

depleted, grass farming for improving, Ky. 507.

development and vegetational changes, quantitative correlations, 205.

diagnosis by universal soil testing system, Conn. [New Haven] 26.

dry-land, nitrogen content, 636.

effect of arsenious, arsenic, and antimony oxides, Mass. 769.

effect of different methods of slash disposal, Conn. [New Haven] 803.

erosibility—

and infiltration capacity, Tenn. 428.

relative, in Puerto Rico, P.R.U. 184.

studies, Wash. 343.

Soil(s)—Continued.

erosion—

- accelerated, in arid and semiarid Southwest, and climate, U.S.D.A. 764.
- and runoff, effect of plant cover, Wash. 343.
- and runoff from agricultural watersheds, tillage practices for, Wash. 343.
- and runoff, measuring, tilt buckets for, 861.
- at State College, year's record, Mich. 182.
- by wind, relation to roughness of surface, 26.
- control, Mo. 120, Okla. 638.
- control by irrigation water, Wash. 343.
- control dams and waterways, experimental, testing, S.C. and U.S.D.A. 429.
- control, place of terracing in, N.J. 342.
- control, relation to cropping practices, Wash. 343.
- effect of micro organisms, 28.
- effect of organic matter on, N.J. 342.
- in farm drainageways, control, 429.
- interplanting tests in hill culture to check, Iowa 220.
- losses of major plant nutrients and organic matter from sandy loam, 638.
- microscopic studies, Iowa 183.
- nature of, Mass. 769.
- on Box Elder Creek project, Nebraska, U.S.D.A. 25.
- on hillsides, control, tests of planting material for, 226.
- on steep land, control, Ky. 769.
- on Vermont permanent pastures, Vt. 638.
- studies, Iowa 183, Mo. 22.
- surveys, U.S.D.A. 184.

fertility—

- composition of alcoholic potato leaf extract and entire leaf as index, 783.
- effect of hay removal, Miss. 366.
- maintaining on irrigated land in Colorado, Colo. 188.
- plant composition as index, 772.
- "quick methods" for determining, Fla. 760.
- studies, N.C. 344, S.C. 342.
- studies in Delta area, Miss. 26.
- under field and greenhouse conditions, Fla. 769.
- flora and fauna associated with roots, methods of observing, 637.
- for petrographic analysis, preparation, 24.
- formation processes, petrographic method for study, 769.

Soil(s)—Continued.

- fumigant, methyl bromide-dichloroethyl ether emulsion as, 826.
- greenhouse, fertility studies, Wash. 343.
- greenhouse, nutrient deficiencies, Iowa 183.
- groups, representative samples, properties, 23.
- heterogeneity, relation to foliar diagnosis, 26.
- hydraulic head measurements with high water tables, 277.
- improving rotations, lysimeter experiments with, Ariz. 768.
- in containers, moisture distribution in, 27.
- inoculation with *Azotobacter chroococcum*, 637.
- iron determination in, 334.
- irrigated, changes occurring in, Wash. 343.
- irrigated, fertility, Wash. 343.
- irrigated orchard, pH values, 27.
- lateritic, aggregation and erodibility, effect of microbial activity, 773.
- light, advantages of long rotations on, Wis. 483.
- loessial, development in central U. S., Mo. 769.
- management practices recommended, Idaho 632.
- manual for Eleventh Farm Credit District, U.S.D.A. 23.
- mechanics nomenclature, 184.
- microbes, acids produced by, importance, N.J. 342.
- moisture—
 - conditions in field, tensiometers for following, 191.
 - equivalent in, relation to field capacity, 27.
 - measurement, development of field apparatus for, Iowa 183.
 - measuring, calibrated soil probe for, 185.
 - relation to pH value, 771.
 - relation to soil temperature, 771.
 - studies, Ariz. 768.
 - tensiometer materials and construction, 186.
- movement within surface profile of terraced lands, 343.
- muck, *see* Muck.
- nitrogen content, *see* Nitrification and Nitrogen.
- of Arizona, properties, effect of organic matter decomposition on, Ariz. 768.
- of Colorado, high lime content, Colo. 642.
- of Connecticut, effect of cultivation and erosion, Conn. [New Haven] 768.
- of Florida, composition, Fla. 760.
- of Florida, reaction, adjustment, Fla. 769.
- of Georgia, lime requirement, determination, Ga. 5.
- of Iowa, liming, Iowa 642.

Soil(s)—Continued.

- of Iowa, microbiological status, effect of water logging and erosion, Iowa 188.
- of Kentucky, phosphorus compounds in, Ky. 769.
- of Massachusetts, availability of potassium, effect of base exchange capacity and of exchangeable ions, Mass. 769.
- of Missouri, colloidal material in, properties, Mo. 22.
- of Missouri, lime requirements and use of lime, Mo. 189.
- of New York, physical condition and maintaining in better tilth, [N.Y.] Cornell 23.
- of Puerto Rico, classification and productivity rating, P.R.U. 25.
- organic matter in, *see* Organic matter.
- pasteurizer, constant-current resistance, 431.
- pasteurizer, insulated electric, 578.
- peat, *see* Peat.
- permeability units for, 772.
- pH and available calcium relations in fields producing scabby and clean potatoes, Mo. 183.
- phosphorus and nitrogen, effects of crop production, S.Dak. 483.
- phosphorus and potassium requirements, fixation method for determining, 774.
- physical reactions on plow disks, 122.
- Podzol, profile in Adirondack forest, effect of submergence, 633.
- probe, calibrated, for measuring field soil moisture, 185.
- productivity, effect of combining residues, Ill. 482.
- productivity, effect of texture and slope of land, N.Dak. 635.
- profiles of different series, properties, Nebr. 634.
- properties and stages of decomposition of organic matter affecting erosion, Iowa 183.
- properties, effect of waste sulfite liquor, 347.
- sampling tube with inner liner, 24.
- San Joaquin, hardpan and clay pan in, 185.
- science problems in need of prompt solution, 342.
- science relation to land-use planning, 768.
- semiarid, productive capacity and present emergency, Ariz. 635.
- shallow, response to good management, Wis. 483.
- shearing strength, technic of determining, 576.
- slick spots or scalds in, Ill. 482.
- soluble material in, relation to their classification and fertility, U.S.D.A. 770.
- structure evaluation, methods, 333.
- structure, nature, and effect on soil tilage, Mo. 22.

Soil(s)—Continued.

- survey in—
 - Michigan, Clinton Co., U.S.D.A. 632.
 - Minnesota, Roseau Co., U.S.D.A. 184.
 - Montana, Golden Valley Co., Mont. 769.
 - North Dakota, McKenzie Co., U.S.D.A. 632.
 - Puerto Rico, U.S.D.A. 343.
 - Texas, Maverick Co., U.S.D.A. 343.
- temperature, relation to soil moisture, 771.
- test plats, historical, experimentation with, Mass. 769.
- tests, quick, use and interpretation, 18.
- tests, rapid chemical, P.R.U. 184.
- tests, rapid, relation to response of truck crops, Fla. 768.
- type and manurial treatments, Iowa 183.
- types, absorptive powers, Ill. 482.
- types of Iowa, characteristics, Iowa 183.
- types of Ohio, manganese status, 346.
- types, potassium availability in, Iowa 183.
- types, productive capacities, estimation, Iowa 183.
- unproductiveness, causes and remedies, Wash. 343.
- virgin, auxin extraction from, 186.
- water, *see* Soil moisture.
- Solar radiation, ultraviolet, spectral range, use, 181.
- Solomonseal seeds, dormancy in, 648.
- Solubea pugnax*, notes, U.S.D.A. 91.
- Solution, large volumes of, continuous liquid extractor for, 474.
- Sorghastrum, host of an undescribed smut, 536.
- Sorghum—
 - and corn in alternate rows, S.Dak. 504.
 - breeding, N.Mex. 366.
 - breeding for low HCN content, S.Dak. 504.
- grain—
 - Coes, feeding value, Colo. 835.
 - culture tests, Fla. 792.
 - for dairy cows, advantage of grinding, 412.
 - ground, v. ground corn in dairy rations, S.Dak. 563.
 - pericarp histology and coloration, 236.
 - storage, 125.
 - variety tests, Ariz. 791, Fla. 791, Idaho 659, N.Mex. 366, S.C. 867, Wyo. 793.
- growing and making sorghum sirup, Mo. 627.
- seed-borne pathogens, detecting, laboratory technics, Iowa 228.
- seed germination, effect of low temperatures, 512.
- sirup, Tenn. 327.
- sirup, increased importance as sugar substitute, Miss. 740.

Sorghum—Continued.

- strain tests, Fla. 791.
- varieties, resistance to chinch bug injury, Okla. 617.
- varieties, turkeying-off, S.Dak. 703.

Sorgo—

- Atlas, as silage crop, adaptation, Ind. 659.
- variety tests, Fla. 791, Idaho 659, Ind. 659, N.Mex. 366, S.C. 367, Wyo. 793.

Sorosportum new species, description, 381.**Soursop—**

- culture, P.R.U. 800.
- flavor and acids in, P.R. 617.
- vitamin C in, P.R. 617.

South Carolina Station report, 435.**South Dakota Station** notes, 612.**South Dakota Station** report, 609.**Sows—**

- brood—*see also* Pig(s) and Swine.
- fattening, protein mixtures for, Ind. 697.
- nutritional requirements, Mo. 98.
- lactating, protein requirement, 98.
- mothering and nursing ability, differences in, 98.
- rye as winter pasture for, Ill. 554.
- with pigs, rations for, Ill. 554.

Soybean(s)—

- and soybean products, feeding, effect on milk production and quality, Iowa 263.
- and Sudan grass mixtures, tests, Ariz. 791.
- as host for immature grasshoppers, Ill. 545.
- availability of P to, Ind. 659.
- Biloxi, floral initiation, effect of grafting, 357.
- breeding, Ill. 504, Ind. 659, Iowa 212, Mo. 52, N.Mex. 366, [N.Y.]Cornell 53.
- carbohydrates, Ind. 616.
- chemical composition during maturation, 783.
- cultural and interplanting with hegari tests, Ariz. 791.
- culture tests, Ill. 504, S.Dak. 504, Tenn. 367, Wash. 367.
- diseases in Georgian S. S. R., 529.
- diseases in North Carolina, U.S.D.A. 66.
- edible, Ala. 740.
- edible, processing studies, Wash. 451.
- edible, testing, Mass. 800.
- edible varieties, Iowa 222, Miss. 304.
- edible, variety tests, S.C. 371.
- effects of boron on, Del. 212.
- fertilizer placement with, Ind. 659.
- fertilizer, seeding rates, and time of harvest for, N.J. 366.
- fertilizer tests, Ind. 659, S.C. 367.
- fibers in mixtures of textile fibers, identification, 318.
- for grain, Miss. 366.
- growing and harvesting methods, Ill. 573.
- grown in Henderson Co., analyses, Ky 100.
- growth, concentrations of essential mineral elements for, Mo. 32.
- growth, effect of B on, Ky. 792.

Soybean(s)—Continued.

- growth, reproduction, and composition, effects of Ba and Sr, Fla. 799.
 - hay yield, planting rate as factor, Miss. 366.
 - improvement, role of hybridization in, 52.
 - Fe-Mn ratio in relation to respiratory CO₂ and deficiency-toxicity symptoms in, 782.
 - iron utilization, differences in efficiency, Iowa 212.
 - lecithoprotein as ice cream emulsifier, Ind. 704.
 - meal and pasture with corn for pigs, Mich. 836.
 - meal as protein source for chicks, Miss. 702.
 - meal in poultry rations, Wash. 404.
 - Mukden and Kanro, adaptation studies, Iowa, 212.
 - nodulation, effect of seed treatment, 666.
 - nodulation, factors affecting, Ill. 504.
 - nodulation in Arizona soils, Ariz. 768.
 - oil, glycerides of, fractionation, Ind. 616.
 - oil meal in broiler rations, value, Mo. 261.
 - oil, nonbreak, production, Ind. 616.
 - oil, nonfat constituents, Ind. 616.
 - photoperiodism and enzyme activity, Mo. 32.
 - place in New Jersey farming, N.J. 366.
 - planting tests, Ind. 659.
 - plants, inoculated and uninoculated, effect of aeration and soil temperature, 777.
 - production, Mo. 666, Nebr. 370.
 - production goals for war needs, Miss. 213.
 - protein, resume and bibliography, U.S.D.A., 618.
 - root structure, effect of root media, Mass. 775.
 - roots and tops, effects of seed weight, 52.
 - seed, chemical composition, factors affecting, Mo. 53.
 - seed, composition, factors affecting, U.S.D.A. 510.
 - seed germination, effect of low temperatures, 512.
 - seed, weak, cause of crop failures, N.Y. State 798.
 - use for silage, Ill. 562.
 - varieties, response to rate and date of planting, Iowa 213.
 - variety tests, Ariz. 791, Ill. 504, Iowa 212, Ky. 792, Me. 213, Mo. 52, N.J. 366, N.Mex. 366, P.R.U. 213, Pa. 504, S.C. 367, S.Dak. 504, Tenn. 367, Wash. 367, Wyo. 793.
 - vitality, effect of storage, Ill. 504.
 - yellow-seeded, variety tests, Del. 212.
 - yields, effect of hailstorms, Ill. 504.
- Spalangia* sp. shipment to Colombia for control of hornfly of cattle, P.R. 695.
- Sparganothis sulfureana* control, 401.

- Species**—
 concept and biosystematy, 32.
 origin of, and genetics, 43.
- Spectrophotometer**, photoelectric, improvements in, Ind. 616.
- Spelt in Michigan**, Mich. 217.
- Spergon**—
 as seed disinfectant, U.S.D.A. 66.
 for sweetpotato treatment, U.S.D.A. 680.
 fungicidal value, U.S.D.A. 377.
 wettable, as disinfectant of seed sweetpotatoes, U.S.D.A. 528.
- Sperm**—
 mamalian, X-radiation of, effect on embryo, 655.
 respiration rate, effect of cell concentration, 500.
 respiration rate, effect of pH, 500.
- Spermatogenesis and sperm morphology in the ram**, Mo. 47.
- Spermatozoa**—
 bull, resistance to unfavorable environment, 209.
 bull, staining affinity, 209.
 live and dead, differentiation, staining method for, 500.
 production by fowls, effect of temperature and season, Ind. 656.
 survival in genital tract of mare, 500.
- Sphaceloma**—
arachidis, notes, 235.
australis, parasite of mandarin oranges, control, 542.
 cause of severe poinsettia disease, 244.
- Sphacelotheca**—
n.spp., description, 381.
sorghastri n.sp., description, 536.
- Sphaeria**, taxonomic data, 487.
- Sphaeronema**, taxonomic data, 487.
- Sphaeropsis malorum**, notes, 220.
- Spider**, red, *see* Red spider.
- Spinach**—
 culture tests, Fla. 799.
 New Zealand, germination, 513.
 rate and course of respiration in, [N.Y.] Cornell, 33.
 seed treatments recommended for, N.Y. State 222.
 variety tests, Fla. 799.
 wilt resistant variety, developing, 67.
- Spinal fluid**, nicotinamide in, bacterial assay method, 480.
- Spittle bug**, notes, Del. 245.
- Sponge**, vegetable, descriptive account, P.R.U. 800.
- Spore resistance to heat**, significance of incubation temperature, 34.
- Spore suspension**, stabilized, for disinfection tests, 34.
- Spray(s)**—*see also* Fungicide(s), Insecticides, and specific forms.
 copper, *see* Copper.
 coverages, nature and effectiveness, Wash. 393.
 dynamite, Pa. 546.
 eradicator, tests, Tenn. 378.
- Spray(s)**—Continued.
 injury, factors affecting, Wash. 372.
 machinery for home orchards, gardens, and truck crops, Miss. 728, 863.
 material(s)—
 improved, from study of residue, Pa. 479.
 saving for war effort, 531.
 shortage, meeting, Conn.[New Haven] 231.
 nonpoisonous, [N.Y.] Cornell, 90.
 oil, *see* Oil sprays.
 on soil, effect, N.J. 342.
 residue problem, Mass. 820.
 residue removal, Wash. 372.
 residue removal, experiments and trends, 395.
 residues on apples, Ind. 668.
 timing for apple maggot control, N.Y. State 256.
- Spraying**—
 equipment for pest control, Calif. 581.
 plants, stationary v. portable, power consumption and costs, Ind. 725.
- Spruce**—
 and fir forests, selective cutting for, Mich. 226.
 cleaning in cut-over hardwood stands, 65.
 sawfly, European, disease of, U.S.D.A. 88.
 sawfly, European, studies, 395.
- Spurge**, leafy, control by sheep, N.Dak. 700.
- Squash**—
 bugs, control impractical on low-value crops, Ill. 546.
 responses to boron, 354.
 stored, causes and control of decay in, Mass. 807.
 summer, hybrid, breeding, Conn.[New Haven] 799.
 vine borer, studies, Conn.[New Haven] 822, Mass. 820.
 wilt prevalence and resistance of Table Queen variety to, Wis. 528.
- Squirrel(s)**—
 damage to conifers, 545.
 ground, pale variation in, 656.
 in southeast Texas, helminths of, 419.
 western fox, ecology and management, Iowa 245.
 western fox, inventory methods applicable to, 545.
- Stablefly**, transmission of equine infectious anemia by, 718.
- Stagonospora subseriata**, notes, 72.
- Stain(s)**—
 for differentiating adult or embryonic bone and cartilage, 629.
 polychrome methylene blue, studies, 629.
 reaction with bacteria, 630.
 standardization, cooperation among Americas, 205.
- Staining**—
 of bacteria and yeasts with acid dyes, 630.
 Romanowsky, with buffered solutions, 629.

Staphylococci—

- of mastitis, bacteriophages for, isolation and characteristics, 421.
- pathogenicity, slide agglutination to determine, 112.

Staphylococcus—

- aureus*, lethal effect of drier rolls on, 348.
- nucleus in cell of, demonstration, 349.

Starch(es)—

- characteristics, elasticity and viscosity, Iowa 165.
- consistency and microscopical properties, 348.
- determination, methods, 335.
- determination with sodium hypochlorite, 336.
- electrical studies, Iowa 165.
- in sausage and other meat products, determination, 336.
- in sweetpotatoes, determination by A. O. A. C. malt-disease method, 176.
- oxidized, methylation and hydrolysis, Iowa 165.
- physicochemical properties, Mass. 760.
- Raman spectra, Iowa 165.
- sodium, methylation, Iowa 165.
- synthesis by vegetable cell, role of invertase in, 780.

X-ray and microscopic studies, Iowa 165.

Statistics, graphic correlation procedure, relation to least squares, U.S.D.A. 283.**Steaks—**

- frozen, drip and evaporation losses, Idaho 739.
- paper in which to wrap, Wash. 404.

Steers—see also Cattle, beef.

- alfalfa-molasses silage v. alfalfa hay for, Ky. 834.
- Brahman and Angus, as feeder cattle, Fla. 833.
- carcass quality in, judging, Ariz. 835.
- fattening—

- comparison of corn, cane, and millet for, S.Dak. 554.

- kudzu and peanut hays for, Fla. 833.

- molasses for, Fla. 833.

- on linseed meal and oil, factors responsible for finish, Iowa 257.

- on winter pastures with supplemental feeding, Fla. 833.

- feeding on corn-cob-shuck-meal with and without cottonseed meal, Tenn. 404.

- feeding with sugar beet tops, molasses, and beet pulp, Idaho 697.

- grazing, forage intake, fecal dry matter as index, 258.

- Hereford, finish and quality, factors affecting, Fla. 833.

- medium, good, and choice, indexes of returns per bushel of corn fed to, Ill. 583.

- selenized, glutathione and thionelne isolation from blood, 421.

- wet beet pulp v. silage for, Wyo. 834.

- wintered with and without grain, summer gains, Tenn. 404.

Steers—Continued.

- yearling, fattening, dehydrated sweet-potatoes for, Tenn. 404.

- yearling, fattening, protein supplements for, comparison, [N.Y.] Cornell 99.

- yearlong grazing in northern Great Plains, U.S.D.A. 258.

- Stegasta bosqueella*, micro leaf worm on peanuts, 247.

Stemphyllum—

- botryosum tragopogoni* n.var., notes, 79.

- sarcinaeforme* from red clover seed, 683.

- Stephanurus dentatus*, control in hogs, 116.

Stercum—

- frustulosum* on sprout oak stands, U.S. D.A. 83.

- gausapatum* causing butt rot in young sprout oaks, U.S.D.A. 83.

- gausapatum* nitrogen metabolism, 808.

- rugosiusculum* on sweet gum, tupelo, and black gum, U.S.D.A. 680.

Sterility—

- in cattle, hormones for combating, [N.Y.] Cornell 47.

- in mice and chromosome breakage, 863.

- somatoplastic, as function of endosperm genotype, 206.

- Sterilizer, multiple-baffle electric, performances of, 865.

Sterols—

- activated, as vitamin D supplements for poultry, Idaho 697.

- activated large doses of, effect on serum calcium, 310.

- derivatives, production and role in nutrition, Iowa 165.

- Sticktight flea, transmission of endemic typhus fever by, 96.

Stillboestrol—

- and oestrone, comparative effects on rat pituitary, 655.

- biological assay, 50.

- potency in immature female rats, 502.

- Stinkbug, Say, studies, N.Mex. 893.

- Stipa lepida*, diploid and autotetraploid, comparative growth rates, 31.

Stock (flower)—

- bacterial disease, cause, 244.

- bacterial blight control by hot-water seed treatment, Calif. 692.

- black rot, 389.

- Stock, see Livestock.

- Stock foods, see Feeding stuffs.

- Stomach worm—

- eastern, in sheep on irrigated pastures, Oreg. 856.

- in lambs and relation to gastric hemorrhage and general pathology, 716.

- length of life in calf, 422.

- outbreak and control, Ariz. 850.

- Stomatal movements, recording, inexpensive manometer for, 32.

- Stomoxys calcitrans*, see Stablefly.

- Stone, cast, proposed specification for, 577.

- Storage, frozen, for farms, Idaho 725.

- Storage studies, Ind. 668.

- Stoves, pressure gasoline and pressure kerosene, analysis, Nebr. 897.
- Straw, baling, with pick-up baler, 863.
- Strawberry (ies)—
- aphid, migration, 251.
 - black root-tolerant selections, testing, Tenn. 378.
 - breeding, Conn. [New Haven] 799, Tenn. 371, Wash. 372.
 - bud nematode, calcium cyanamide for, Fla. 806.
 - composition, Tenn. 327.
 - crown borer control with methyl bromide, 396.
 - crown borer, methyl bromide fumigation for, Ky. 822.
 - cultural tests, Iowa 220.
 - culture, U.S.D.A. 224.
 - fertilization, N.J. 371.
 - fertilizer tests, Iowa 220.
 - for home garden, N.J. 520.
 - fruit, developmental studies, 31.
 - insects, control, Mo. 85.
 - insects, life history and control, Wash. 92.
 - irrigation studies, Iowa 220.
 - leaf roll, a new disease, 816.
 - leaf spot, cause, P.R.U. 229.
 - plant, growth and composition, effect of source of N and pH of nutrient medium, N.J. 63.
 - poultry manure for fertilizing, Del. 220.
 - production, factors affecting, Iowa 673.
 - production in Ohio, Ohio 63.
 - red stele disease—
 - breeding for resistance, Ill. 516.
 - control, Del. 227.
 - on Pathfinder and Aberdeen varieties, U.S.D.A. 680.
 - promising resistant crosses, 241.
 - "running out" diseases, Wash. 378.
 - spring dwarf situation on Cape Cod, U.S.D.A. 680.
 - transpiration, effect of root temperature, 520.
 - varieties, inheritance of characteristics in, 520.
 - variety tests, Iowa 220, P.R.U. 221.
 - virus diseases, 541.
 - weevil, barium fluosilicate and cryolite against, Del. 245.
 - weevil, dusting for control, 303.
- Stream flow—
- measurements in Colorado River, Snake River, and Pacific slope basins, 725.
 - open-channel, profile curves for, 574.
- Streptococci—
- hemolytic, additional growth factor needed by, 420.
 - hydrolysis of arginine by, [N.Y.]Cornell 83.
 - isolation, sodium azide for, 179.
 - lactic acid fermentation of, 776.
 - mastitis, dehydrogenase systems of, [N.Y.]Cornell 33.
 - mastitis, variability, [N.Y.]Cornell 109.
- Streptococci—Continued.
- of group B, variability in, 420.
 - of Lancefield's group B or C in milk samples, detection, 714.
 - of Lancefield's group C, fibrinolytic properties, 420.
 - respiratory mechanisms, [N.Y.]Cornell 83.
 - riboflavin reduction by, [N.Y.]Cornell 33.
 - synthesis of polysaccharides by, [N.Y.]Cornell 33.
- Streptococcus*—
- agalactiae*—
- eradication from bovine mammary gland, 421.
 - examination of nose, throat, and vaginal swabs from cows and of dung samples for, 566.
 - in udders of heifers at parturition, 422.
 - in various plating media, growth, 106.
- fecalis*, morphological study, 35.
- lactis*, aging without reproduction and viability of young cells, 776.
- lactis tardus* in Virginia milk, effect on quality, 413.
- thermophilus*, growth factors, 180.
- Streptothricin, new selective bacteriostatic and bactericidal agent, 348.
- Strongyles in horses, control, [N.Y.]Cornell 109.
- Strongyloides*—
- in dogs, diagnosis, 274.
- papillosa* in sheep on irrigated pastures, Oreg. 856.
- robustus* n.sp. in squirrels, 419.
- Strongylus vulgaris* tests with organic copper salts, 420.
- Stylopaga cephalote*, notes, 530.
- Succinic acid—
- as metabolite in plant tissues, 168.
 - synthesized by heterotrophic bacteria, position of carbon dioxide in, 168.
- Sucrose, rate of inversion, 175.
- Sudan grass—
- and soybean mixtures, tests, Ariz. 791.
 - culture tests, Wyo. 793.
 - fertilizer tests, Wyo. 793.
 - grazing value, Tenn. 367.
 - leaves, protein-nitrogen, protein-sulfur, and chlorophyll in, relations, 203.
 - new hybrid variety for Southeast, 535.
 - pastures, yield and composition, Ariz. 841.
 - single plants, determining hydrocyanic acid content, 479.
 - trace elements in, 52.
- Sugar beet(s)—
- aphids affecting, 394.
 - black root control, Wash. 378.
 - boron deficiency in, borax spray or dust for control, Wis. 528.
 - breeding, N.Mex. 366.
 - costs and management in irrigated areas, Nebr. 868.

Sugar beet(s)—Continued.

- culture in intermountain area with curly top-resistant varieties, U.S.D.A. 795.
 - culture tests, Wyo. 793.
 - curly top control, U.S.D.A. 796.

- Java black rot in Georgian S. S. R., 529.
- keeping quality, relation to time of digging, N.J. 366.
- meal v. corn for finishing calves, Miss. 835.
- Nancy Hall strain selected for color of flesh, Tenn. 666.
- nutrient absorption by, effect of fertilizer placement, Del. 212.
- plant production, electricity in, S.C. 367.
- Porto Rico, improvement, S.C. 367.
- pox, N.J. 813.
- production for starch or feed purposes, La. 796.
- Rhizopus* soft rot, losses from and control, N.J. 377.
- scurf, black rot, and stem rot similarities and control, N.J. 686.
- scurf control and chloranil, U.S.D.A. 377.
- seed stock, disease-free, propagation, Iowa 228.
- starch, fertilizers for, Miss. 370.

Sweetpotato(es)—Continued.

- starch in, determination by A. O. A. C. malt-diastase method, 176.
- storage house construction, effect of electric heating systems on, 125.
- storage quality, fertilizer and varietal factors in, Iowa 213.
- storage tests, Fla. 760.
- variety tests, Iowa 212, P.R.U. 213, Tenn. 367.
- weevil control and eradication, U.S.D.A. 88.
- wilt control, Del. 227.
- yields, relation to times of planting and digging, N.J. 366.

Swine—see also Pig(s) and Sows.

- arthritis, Wash. 418.
- Breeding Laboratory, regional, organization and development, 208.
- chromosome counts, Mo. 47.
- Duroc-Jersey and Poland China, reciprocal crosses, Mo. 47.
- Duroc-Jersey, inheritance, Mo. 47.
- erysipelas, chronic, control, 273, Idaho 709.
- erysipelas in turkeys, treatment, 119.
- Poland China, inbred lines, improvement, Mo. 47.

Sycamore plant bug control, 397.

Sylvatic plague vectors in North America, 89.

Symphyliid(s)—

control, 391.

greenhouse, relation to dry soil, Pa. 546.

Synopsis and chiasmotypy, present status, 31.

Synohytrium endobioticum studies, 236.

Tabanids, unusual larval habitats, 90.

Tabanus sulcifrons, transmission of equine infectious anemia by, 718.*Taeniothrips simplex*, see *Gladiolus* thrips.

Tamarisk tree and its wood, Ariz. 859.

Tannins, determination, 338.

Tapeworm, fowl, removal by short periods of starvation, 571.

Tariffs, quantity incidence on competing products, U.S.D.A. 289.

Tarnished plant bug, effect on sugar beet seed production and control, U.S.D.A. 88.

Taro leafhopper, control with egg-sucking bug, 89.

Tarsonemus—

bancrofti, eradication, U.S.D.A. 88.

pallidus, see Cyclamen mite.

Tartar emetic sprays, sugar substitute in, 396.

Tax(es)—

- and governmental costs in rural New York, [N.Y.]Cornell 130.
- assessment procedure and problems, S.Dak. 439.
- collections, State, and allocations by parishes, La. 289.
- delinquency on rural real estate, bibliography, U.S.D.A. 288.
- delinquency, relation to land use, N.J. 434.

Taxation in oil-producing areas, Okla. 780.

Taxonomy, experimental—

approached from various standpoints, 485.

with criteria for relationship, 485.

Taxus mealybug, pest of genus *Taxus*, 828.

Tea bush, micro-organisms of and diseases caused by them, 242.

Tea, effect on energy metabolism of children, 888.

Tea fermentation, chemistry of, 192.

Teak defoliators, parasites of, biology, 395.

Teat sphincter, anatomy and physiology, 267.

Teeth—

conditions in childhood, pediatric aspect, 156.

decay and drinking water, 800.

decay, relation to *Lactobacillus acidophilus* in saliva, 890.

developing, in rats on vitamin A-deficient diet, changes in, 600.

dietary repair of experimental caries in, 462.

effect of prolonged vitamin deficiencies, 598.

incisor, of rachitic rats, effect of vitamin D on, 460.

mottled, relation to fluorine in water supply, 163.

mottled, removal of stain from with hydrogen peroxide, Ariz. 760.

mottled, removing brown stain from, 462.

of rats, experimental caries, reduction by fluorine, 598.

substance of, potassium in, spectrochemical studies, 462.

Tennochila virescens chlorodia, predator of mountain pine beetle, 95.

Temperature(s)—see also Climate(s) and Soil temperature.

air, and fruit, relation, 341.

difference, role in ontogenesis of vegetables, 353.

of -12° F. or lower, frequency in thirty winters, Mich. 767.

Tenebroides corticalis predaceous on codling moth larvae, 247.

Tennessee Station report, 465.

Tensiometers, use for observing soil moisture under corn, Iowa, 183.

Tent caterpillar, eastern, Del. 245.

Teosinte and corn, cytogenetic study, Mo. 359.

Tephrosia—

roots, toxic constituents in, relation to carbohydrates, P.R. 617.

virginiana, rotenone-bearing variety in New Jersey, 826.

Termite(s)—

control, 397, Ill. 546.

damage, protection of buildings against, U.S.D.A. 88.

injury, prevention, N.J., 391.

studies, 894.

Terrace(s)—

- dependence of efficiency on maintenance, Ill. 573.
- grades on Shelby soil, relation to soil and water losses, 861.
- old farmer-built, studies, 430.

Terracing—

- place in soil erosion control, N.J. 342.
- practices, test, 187.

Terrapin scale control with insecticides, 395.**Testis reaction to synthetic androgens, 655.****Testold compounds, morphogenetic actions, differences between, 654.****Testosterone—**

- effect on responsiveness of immature gonad to chorionic gonadotropin, 51.
- propionate, effect in spayed female rats, 658.

1,4,5,7-Tetrahydroxy-2-methylantraquinone, synthesis of, 349.***Tetranychus* spp., see Red spider.****Texas Station—**

- notes, 468.
- publications available, list, 899.

Textile—see also (Fabric(s)).

- fabrics and their selection, 752.
- materials, cross sectioning by hand, 157.
- materials, nonmetallic, new and revised standards, 156.
- materials used for household purposes by farm families, S.C. 608.
- photomicrographs made at low power by fluorescent light, 752.
- research, Pa. 607.
- research aid, air permeability, instrument, 753.
- tests, application of rank correlation to development of methods, 462.

Thamnopydes* n.spp. and biology, 546.**Theresia olaripalpis*—**

- liberations at Guayama, P.R. 595.
- parasite of *Diatraea* spp. in Trinidad, 552.

Thermocouples, tube-wall, method of installing, 171.**Thermogenesis, microbial, Iowa 183.****Thiamin—see also Vitamin B₁.**

- and growth of *Pythium*, 351.
- and its degradation products in man, excretion, 894.
- and riboflavin in food products, combined determination, 10.
- and riboflavin metabolism, 698.
- deficiency and Chastek paralysis in foxes, 858.
- deficiency, effect on citric acid excretion, 815.
- deficiency, effect on fatal pneumococcal infection in mice, 110.
- deficiency in rats, effect on pyruvic acid excretion and bisulfite-binding substances in urine, 315.
- depletion tests, bisulfite binding substances in, 149.
- determination by thiochrome reaction, 9.
- determination in urine, effect of ingestion of nicotinic acid on, 480.
- rate in digestive secretions, 149.

Thiamin—Continued.

- hydrochloride, sensitization to, 608.
- in agar, 89.
- in cereals, thiochrome method of analysis, 9.
- in green snap beans, effect of freezing, canning, and dehydration, 891.
- in human blood and urine, determination, 602.
- in rye and its milled products, 146.
- in soft wheat mill streams, 148.
- in urine, estimation, 620.
- in wheat and corn, 148.
- in wheat milling products and in bread, 604.
- in wheat of different types and grown in different environments, 604.
- in wheat of 1940 crop, 603.
- metabolism in humans and rats, Ariz. 880.
- requirements and environmental temperatures, 602.
- requirements of albino rat, 698.
- requirements of pigs, relation to fat in diet, 98.
- studies on older subjects, 314.
- transport in tomato plant, 488.
- urinary excretion on high fat and high carbohydrate diets, 149.

***Thielaviopsis*—**

- basicola* infection of geranium cuttings, 388.
- paradoxa*, notes, 535.

Thiobacillus thiooxidans*, sulfur oxidation by, significance of fat in, 193.*Thistle hoppers, epizootic among, 247.****Thiuram disulfide for turf and for treating seeds, N.J. 810.*****Thlaspi arvense* seed germination, 512.****Thresher, home-made, for castor-beans, 579.****Thrips—**

- control, in greenhouse, U.S.D.A. 88.

predaceous, notes, 397.***Thrips tabaci*, see Onion thrips.****Thrombin, purification, 160.****Thurberia weevil control, U.S.D.A. 88.****Thyroid—**

- activity, effect of progressive iodination of skim milk and casein on, 267.
- gland of female rats, mitotic activity, 654.
- gland of guinea pig during sexual cycle, proliferative activity, 508.
- iodine in, determination, modified method, 178.

Thyroidectomy, effect on lactation in rat, 105.**Thyrolactin feeding, effect on milk production, 705.****Thyroprotein, artificial, production, 8.****Thyroxin effect on—**

- blood sugar and glycogen stores of hypophysectomized rats, 503.
- insulin of rat pancreas, 503.
- milk production, Mo. 103.

Thysanoptera new to island of Midway, 547.**Tick-bite fever, transmission, brown dog tick, 851.**

Tick(s)—

- affecting animals, U.S.D.A. 89.
- affecting birds' eyesight, 246.
- affecting man, U.S.D.A. 89.
- coast, problem in British Columbia, 97.
- host immunity to, 90.
- infesting livestock in Southern Rhodesia, 696.
- of Minnesota, 403.
- parasites on Cape Cod, 553.
- winter, ecology, 89.

Tift Sudan, new variety of grass for South-east, 535.

Tilling costs and systems, N.J. 428.

Tillage, subsurface, equipment for, 123.

Tilletia—

- levis*, new races, 71.
- levis* on wheat, new races, Wash. 378.
- new species, description, 381.
- tritici*, new races, 71.
- tritici* on wheat, new races, Wash. 378.

Timber—see also Wood(s).

- structural, anobid beetle damage to, 400.
- volume, rapid and reliable estimates, 804.

Timothy—

- and Ladino clover mixture, methods for ensiling, Me. 264.
- composition of tops and roots at successive growth stages, 473.
- development, effect of soil temperature, 196.
- nitrogen fertilization for, [N.Y.]Cornell 53.

Tissue(s)—

- and slides, convenient washing devices for, 628.
- disintegrator, circular revolving brush as, 331.
- sections, cutting on sliding microtome by "dry ice" method, 359, 627.
- transferring, simple method, 359, 628.

Tlascala finitella, notes, Mass. 820.

Toad, giant, shipment to Cuba, P.R. 695.

Tobacco—

- and products, stored, insects attacking, control, U.S.D.A. 823.
- and tomato, reciprocal grafts, accumulation of nicotine, 201.
- auction markets, organization, Ky. 866.
- bacterial leaf spot infection, sources, Fla. 806.

- diseases, studies, Conn.[New Haven] 813, Tenn. 378.
- downy mildew—
 - control, 237, Fla. 806, S.C. 378.
 - control in seedbeds, Conn.[New Haven] 805.
 - gas treatment for, U.S.D.A. 76.
 - spray for, U.S.D.A. 527.
- farms, improving low incomes on, U.S.D.A. 289.
- farms, small, planning for conservation, N.C. 438.
- fertilizer and manuring experiments, Wis. 505.
- fertilizer placement and relative efficiency of N carriers, Conn.[New Haven] 791.
- fertilizer tests, Ky. 792, Pa. 504, Tenn. 367, Wis. 218.
- flea beetle, insecticides against, laboratory tests, 831.
- flea beetle on cigar-type tobacco in South, U.S.D.A. 394.
- flue-cured—
 - adjustable spray boom for treating, S.C. 378.
 - cold injury to seedlings, 587.
 - diseases in North Carolina, U.S.D.A. 66.
 - production, Fla. 792.
- growers, need of credit and variations in production credit terms, P.R.U. 284.
- hornworm control, U.S.D.A. 88.
- hornworm, median lethal dose of insecticides for, Tenn. 393.
- hornworm, notes, Tenn. 393.
- hornworm on cigar-type tobacco in South, U.S.D.A. 394.

Tobacco—Continued.

- insect damage in Connecticut Valley, 248.
irrigation, Conn.[New Haven] 797.
K carriers and rates and improvement of curing process, S.C. 387.
leaf-curl, new petunia strain, 76.
leaves, invasion by *Phytophthora tabaci* and *P. angulata*, relation to moisture, 383.
low-grade, search for new uses for, Ky. 764.
moisture in, determination methods, 347.
mosaic and tobacco necrosis viruses, separation, 77.
mosaic, breeding for resistance to, 230.
mosaic in Ontario and Quebec, 687.
mosaic virus—
 active crystalline fraction of, Mo. 87.
 analysis for biotin, riboflavin, and pantothenic acid, 813.
 derivatives of, 77.
 effect on cellular respiration, 237.
 extracted, unpreserved for 28 years, infectivity, 687.
 inactivation by X-rays, effect of pH on, 814.
 liquid crystals of, 813.
 protein, cystine in, colorimetric determination, 5.
 protein in plant extracts, determination, 384.
 protein, method for assay, 620.
 protein particle, size and shape, 237.
 reversible inactivation by crystalline ribonuclease, 237.
 specific biological activity, factors affecting, 814.
 strains, aromatic amino acids in, 384.
 strains, chemical composition, 77.
 strains, variations in cytoplasmic inclusions induced by, 384.
 structure and activity, effects of iodine and other reagents, 237.
moth—
 control, U.S.D.A. 88.
 in tobacco warehouses, natural enemies of, 822.
 notes, 551.
phosphorus starvation causing leaf spotting, Fla. 806.
plant bed(s)—
 diseases in, U.S.D.A. 66, 528.
 fertilization, Fla. 792.
 green June beetle larvae in, control, S.C. 393.
plants, enzymatic activities, 536.
plants, healthy and mosaic-infected, respiration in, 813.
plants, physiological studies, 797.
production, prices, purchasing power, consumption, etc., P.R.U. 284.
root knot infestation, reducing, culture practices for, Fla. 806.
root knot nematode, cultural measures for control, 238.
rotations, Pa. 504.

Tobacco—Continued.

- seed of six varieties, certified, growing, Wis. 505.
seedbed disease survey in Massachusetts, U.S.D.A. 680.
seedbed diseases in Maryland, U.S.D.A. 680.
seedbed infection by *Rhizoctonia solani*, 78.
seedbed, soil treatments for damping-off and weeds in, Mass. 806.
shade, development of improved types, Conn.[New Haven] 791.
soils, survey, Wis. 184.
thrips, Conn.[New Haven] 822.
United States, trends in demand and consumption, Ky. 866.
variety tests, Tenn. 867.
Virginia flue-cured, quality, relation to bacterial flora, 33.
virus disease, possibility of transmitting by spraying extracts of mosaicked plants, 77.
warehouses, open-type, fumigation, 823.
wildfire control, Tenn. 378.
wildfire, micro-organism associated with, Pa. 686.
yield and quality, factors affecting, Mass. 792.
Tolyposporium senegalense and *T. bullatum*, synonyms, 230.
Tomato(es)—
 Alternaria blight, spraying and dusting for, Tenn. 378.
 Alternaria defoliation of, Conn.[New Haven] 805.
 and tobacco, reciprocal grafts, accumulation of nicotine, 201.
 blossom-end rot, varietal resistance to, 79.
 Bounty, yield, N.Dak. 222, 669.
 breeding, Conn.[New Haven] 799, Ill. 514, Mass. 800, Pa. 513.
 breeding and selection under local conditions, Fla. 799.
 breeding for *Fusarium* wilt resistance, Ind. 668, Mo. 67.
 breeding for resistance to defoliation diseases, Ind. 668.
 canned, quality, Ind. 668.
 cost of production, P.R.U. 290.
 crosses, genetic studies, 45.
 crown gall infection, 689.
 cultural practices, Ill. 514.
 culture, Del. 220, N.J. 371, Okla. 222, Tenn. 371.
 culture in greenhouse, N.J. 669.
 curly top, menace to production in Utah, Utah 239.
 curly top resistance in hybrid strain, Idaho 679.
 damping-off of seedlings, control, Pa. 528.
 danger in planting on soil infected with bacterial wilt, N.J. 377.
 defoliation, causes, effects, and control, Conn.[New Haven] 688.

Tomato(es)—Continued.

defoliation control by manganese sulfate spray, U.S.D.A. 527.

defoliation disease, measuring magnitude, 79.

diploids and tetraploids, genetic stability, 653.

diseases, control, Fla. 806.

diseases, important, survey of genus *Lycopersicon* for resistance to, U.S.D.A. 690.

double-hill planting, 2.

fertilizer placement with, Pa. 513.

fruit(s)—

Aphelenchoides ritzema-bosi in, 539.
genetic characters resembling symptoms of disease, 359.

on plant, respiratory and ripening behavior, 493.

response to methyl-bromide fumigation, 60.

set and development, effect of indolebutyric acid, 515.

fruitworm control, Tenn. 393, Wash. 394.

fruitworm studies, S.C. 393.

Fusarium pathogenically variable strains, difference in pH relations, 239.

Fusarium wilt, N.J. 815.

Fusarium wilt resistance, Tenn. 378.

genetics studies, Iowa 208.

greenhouse, effects of mosaic-inducing viruses, 690.

greenhouse, fertilization, Ill. 514.

greenhouse, sources of organic matter for, Mass. 800.

growing, costs and profits, P.R.U. 284.

growth, effect of soil temperature, Mass. 775.

growth, reproduction, and composition, effects of Ba and Sr, Fla. 799.

haploid, diploid, and tetraploid, epidermal patterns in, 191.

late, combined sprays for, 240.

leaf-spot resistant varieties, breeding, Tenn. 371.

leaf spots and fruit rots, spraying for, 229.

Maine-grown varieties, ascorbic acid in, 606.

mulching, Mass. 800.

new fertilizer practices and starter solutions for, 669.

Pan America, yield on *Fusarium* wilt infested soil, 239.

Phytophthora fruit rot, 229.

pigments, effect of external factors, 200.

plant(s)—

approach-grafted, water and nutrient intake, effect of solute concentration, 32.

ascorbic acid content, effect of potassium iodide, Ky. 800.

culture under artificial light, bibliography of, 784.

effect of phenylacetic acid and naphthalene acetamide on, 352.

Tomato(es)—Continued.

plant(s) continued.

effect of topping on fruit set and yield, 223.

hardened with nutrient solutions, growth and yield, 222.

response to α naphthaleneacetamide and phenylacetic acid, 39.

seedling, testing for disease resistance, 539.

set of, effect of growth substances, Mo. 57.

sprayed, as seedlings in Georgia and Ohio, comparison, Ohio 239.

tests as guide to fertilizers, 222.

variety, spacing, and staking, interrelations, 515.

production for canning, Okla. 373.

production for canning and manufacture, U.S.D.A. 373.

production, trends by areas, U.S.D.A. 60.

psyllid, immature stages, effect of insecticides, 250.

puffing, Fla. 799.

Pythium spp. on, Mo. 67.

quality studies, Ind. 668.

research in South, symposium, Tex. 899.

ring spot on currant, 691.

roots, excised, specificity of pyridoxine for, 488.

roots, isolated, reversible growth inhibition, 32.

seed disinfection, injury from, 539.

seed production, Ind. 668.

seed, vernalization, 515.

seedlings, *Alternaria solani* infection of, 386.

selling on graded basis, Ind. 730.

shape index, Mass. 800.

spraying, Ill. 514, Wis. 513.

tip blight in West Virginia, cause, U.S.D.A. 680.

treated with calcium chloride, calcium pectate as tissue-firming compound, 329.

use of starter solutions for, Pa. 513.

vapo-dusting, Fla. 806.

varieties, N.Mex. 371, Wis. 513.

varieties, F_1 combining ability, 653.

variety, new, development, S.Dak. 513.

variety tests, Iowa 220, Mo. 57.

virus diseases, 539.

wilt resistance, development, 539.

Topsoil removal, Mass. 769.

Towels, water absorption by, 464.

Toxemia in sheep, Mo. 108.

Toxoplasma infection in animals, 567.

Tracheitis, infectious, in chicken, transmission by contaminated eggshell, 721.

Tractor(s)—

costs of operation, Ind. 729.

costs of operation in 1930 and 1940, Ky. 866.

effects on farming in Minnesota, U.S.D.A. 297.

Tractor(s)—Continued.

- farm, use in Minnesota, U. S. D. A. 97.
- farming, conversion of horse machinery for, S.Dak. 573.
- new life for, rubber tires and high compression as source, Ill. 573.
- release hitch, automatic, adaptation of field gun recoil mechanism principle to, Pa. 573.
- tests of Nebraska, Nebr. 280.

Trade—

- foreign, and agriculture, [N.Y.]Cornell 130.
- foreign, effects of exchange depreciation, [N.Y.]Cornell 876.
- relations, Canada-United States, 582.

Tragopogon dubius response to length of day, 204**Transpiration**—

- from natural surfaces, 632.
- rate of yellow coleus plants, effects of inert dusts, 197.

Tree(s)—

- attacked by root diseases, rejuvenating, 531.
- boron content, 190.
- coniferous, *see* Conifer(s).
- diseases, Mass. 806.
- diseases, studies, importance to national defense, Mass. 806.
- effect of blizzard of 1940 in Iowa, 767.
- evergreen, *see* Evergreen(s).
- forest, growth, effect of fertilizers, [N.Y.]Cornell 65.
- forest, root development, effect of soil types, Conn.[New Haven] 803.
- fruit and ornamental, toadstool root rot of, 542.
- fruits, varieties, N.Mex. 371.
- growth and environmental complex, 803.
- growth, effect of different methods of slash disposal, Conn.[New Haven] 803.
- growth in shelterbelt, effect of fertilizer and culture, S.Dak. 513.
- growth, prairie soil as medium for, 65.
- hardwood—

Fomes fomentarius on, biology, Me. 693.

forest lysimeter studies under, Conn. [New Haven] 575.

intolerant, improvement cuttings in, 65.

native, use for fencing, Conn.[New Haven] 800.

southern, machining and related characteristics, U.S.D.A. 577.

injection methods, 381.

nursery, production for erosion control, 226.

of New Zealand, natural root grafts in, 196.

of Puerto Rico, U.S.D.A. 803.

ornamental, testing, Wash. 372.

planting, use of lime and phosphorus in, Mass. 800.

pruning on home grounds, Miss. 60.

Tree(s)—Continued.

- seeds, viability testing, advances in, 43.
- shade and forest, insects affecting, U.S.D.A. 88.
- shade, damaged, care of, U.S.D.A. 803.
- shade, lightning protection for, 129.
- shelterbelt, *see* Shelterbelt(s).
- species, root distribution in different soils, Conn.[New Haven] 276.
- volume tables for Indiana, Ind. 676.
- wrapping for protection from borers, Ill. 546.

Trefoll, birdsfoot, tests with, [N.Y.]Cornell 53.

Trematostoma, taxonomic data, 487.

Triatoma spp. feeding, reactions of man to, 93.

Tribolium confusum, *see* Flour beetle, confused.

Trichinella spiralis—

- active immunity in mice against, 712.
- immunity to in rat, passive transfer, 712.
- infection in man and animals in New Orleans area, 852.

Trichinosed rats, metabolism during early phase of disease, 421.

Trichinosis, in rat, effect of X-ray, 712.

Trichogramma minutum—

- for control of sugarcane borer, P.R.U. 248.
- parasite of sugarcane borer in Florida, 95.

Trichomonas—

- foetus*, animal inoculations with pure cultures, 713.
- foetus* in house fly, viability, 392.
- foetus* in slaughtered cattle, 568.
- foetus*, infection of cows, 113.
- gallinae* in birds, studies, 421.
- gallinarum* in turkeys, fever therapy for control, 426.
- vaginalis*, animal inoculations with pure cultures, 713.

Trichomoniasis, rare in chickens found in two flocks in State, Ill. 504.

Trichophyton mentagrophytes, notes, 719.

Trichopoda pennipes, parasite of *Anasa tristis*, 402.

Trichosphaeria sacchari, notes, 535.

Trichuris ovis in sheep on irrigated pastures, Oreg. 850.

Trifolium repens, multiple oppositional alleles causing cross-incompatibility in, 206.

Trioxa maura predators, 247.

Triticinae—

- amphidiploids n, Mo. 207.
- chromosome pairing and fertility in hybrids, Mo. 207.

Triticum sativum, glandular epithelium of scutellum, cytoplasmic inclusions in, 784.

Tritrichomonas foetus, possible cause of early abortion in herds, Ill. 564.

Tropaeolum majus stem cuttings, development of adventitious roots, 31.

Trousers of wool and part-wool fabrics, wear tests, S.Dak. 608.

Trout—

- management at Great Smoky Mountains National Park, 545.
- nutritional requirements, [N.Y.]Cornell 85.
- streams, closed, overpopulation of, Pa. 546.

Truck crop(s)—

- cooperative marketing, financial results, P.R.U. 294.
- diseases in Massachusetts, U.S.D.A. 805.
- erosion project, Tenn. 342.
- farms, income and profit increase on, Miss. 730.
- fertilizer requirements, Wash. 372.
- grown at different fertility levels, variety tests, Fla. 799.
- insects control with thiocyanate-derbris dusts, 821.
- phenological tests, Fla. 799.
- selection and breeding, Wash. 372.
- spray machinery for, Miss. 863.
- variety tests, Wash. 372.
- virus diseases of, ornamentals as carriers, 238.
- water tables for, Fla. 799.
- yield, factors affecting, 513.

Trucks—

- for hauling livestock, operating costs, charges, and earnings Ill. 583.
- importance in transportation of vegetables, P.R.U. 871.

Trypanidius nocturnus, new beetle from Puerto Rico, P.R.U. 400.

Trypanosoma congolense in cattle, action of aromatic diamidines on, 113.

Tubercle bacilli, bovine, in sputum, 713.

Tuberculin, avian and mammalian, determining sensitizing agent in cattle tested with, 114.

Tuberculosis—

- extrapulmonary, in northern Italy, bone, joint, and cervical lymph node lesions in, 715.
- in Tropics, especially Uganda, 114.

Tularemia, latent feline and human infection, 713.

Tulip(s)—

- bulb production in Upper Peninsula, Mich. 803.
- flower bud formation, time and manner, Iowa 220.
- stem and bulb cutworm new threat to, 389.

Tulipa, critical period for floral initiation in, 191.

Tumors—

- epithelial, of horses, 718.
- genetic resistance to, [N.Y.]Cornell 47.

Tung trees—

- investigations, work of U. S. Field Laboratory for, Fla. 799.
- propagation, planting, and fertilization tests, Fla. 799.
- root development, effect of cultivation and sod treatment, Miss. 376.

Turf—

- bent, from self- and open-pollinated seed and from stolons comparison, 214.
- diseases, thiuram disulfide for, 810.
- fertilizer formulas and relative value of nitrogen sources, [N.Y.]Cornell 53.
- fine, experiments, N.J. 366.
- grasses, plowing, mowing, and cutting, N.J. 366.
- white grub control in, Ind. 604.

Turkey(s)—

- blood protozoan transmitted by *Simulium nigroparvum*, 724.
- breeding and growing, Ind. 698.
- eggs, hatchability, effect of rations, S.Dak. 554.
- eggs, hatchability, effect of temperature, N.Dak. 841.
- eggs, hatchability, relation to relative humidity, Ky. 834.
- fed different grain rations, growth and quality of meat, Wyo. 834.
- flocks, hexamitiasis in, 426.
- nutritional requirements, Mo. 99.
- on range, reduction of feed costs by use of whole oats, Pa. 554.
- poults, choline and mineral requirements, Wash. 404.
- poults, poisoning by whorled milkweed, 572.
- poults, rations for, Wash. 404.
- poults, vitamin D requirements, 562, Wash. 404.
- production, limited range for, 562.
- riboflavin requirement for fertile egg production, Pa. 554.
- sex-linked albinism in, 363.
- sorghums and proso millet for, S.Dak. 554.
- vitamin D requirements, Pa. 554.
- wild, wheat and corn ideal feed for, Pa. 546.

Turnip(s)—

- brown heart, control, 229.
- greens, food value and yield, effect of soils and fertilizers, Miss. 887.
- nutrition of, 535.
- wild, and swedes, distinguishing seeds of, Wis. 505.

Twilight period, photoperiodically effective, length of, 356.

Tylenchus coffeae, host plants of, 817.

Tyloderma fragariae, see Strawberry crown borer.

Typhlocyba pomaria, see Apple leafhopper, white.

Typhoid, fowl, breeding for resistance to in laboratory animals, Iowa 209.

Typhoidlike diseases, breeding for resistance to in laboratory animals, Iowa 209.

Typhula itoana causing snow mold of grasses, Pa. 528.

Typhus fever, endemic, transmission experiments with sticktight fleas, 96.

Tyrocidine studies, 852.

- Tyrothricin, effect on bacteriophage and bacterial toxins and toxinlike substances, 710.
- Udder --
bovine, suspensory apparatus of, 705.
infection, method of detection, 567.
- Ultraviolet --
absorption of cells, increase during irradiation, 204.
light, effect on equine encephalomyelitis virus protein, 424.
light, use on laying flock, Mich. 262.
- U. S. Department of Agriculture --
Bureau of Entomology and Plant Quarantine, *see* Bureau of Entomology and Plant Quarantine.
landmarks in history, U.S.D.A. 302.

- Nomenclature, International Committee on, history, 530.
- propagating, use of developing chicken eggs for, Ill. 564.

Virus(es)—Continued.

- symptoms in leaves, darkening technic for inducing, 530.

Vitamin A—

- and carotene absorption by chickens, relation to lecithin, N.J. 403.
- and E, interaction, 891.
- and injected carotene, comparative physiologic value, 892.
- assays of plant tissues, sources of error in, 6.
- concentration by adsorption, 479.
- deficiency—
 - and urinary calculi in livestock, Colo. 851.
 - chronic, effect on bacterial flora of rats, 599.
 - in children and adults of Newfoundland and Labrador, 313.
 - in dairy cattle and carotene in blood plasma, 844.
 - measure of, 313.
 - ocular manifestations, detection by biomicroscopy, 742.
 - Pett visual test for, 145.

deficient diet of calves, pathology, 114.

deficient diet of rats, changes in structure of teeth on, 600.

determination, 6.

determination, Carr-Price reaction of carotenoids as source of error in, 479.

effect on gastric juice secretion in deficient hydrochloric acid production, 145.

human excretion of, 749.

in blood and liver of chicks, effect of ethyl alcohol and tricesol, 261.

in blood of children, 312.

in blood plasma of dairy calf, vitamin A intake requirement, 705.

in butter, feeding of cows to control, 105.

in butterfat, Ind. 616.

in milk, effect of levels of shark-liver oil in ration, Fla. 842.

in rat, effect of dibenzanthracene, of alcohol, and of other agents, 892.

intake, high, effect on blood and milk carotene of cows, 844.

noncrystallizable, 892.

photoelectric photometer for determination, 5, 6.

potency of fish oils, 138.

relation to animal diseases, 710.

requirements of chicks and layers, 261.

stability in cod-liver oil mixed with feed, effect of manganese sulfate, 555.

utilization, effect of α -tocopherol and unsaturated fatty acids, 698.Vitamin B₁—*see also* Thiamin.

as fertilizers, Tex. 225.

assay, evaluation of fluorophotometers for, 620.

at different soil temperatures, effect on gardenia chlorosis, Mass. 807.

Vitamin B₁—Continued.

deficiency—

and flour milling, 603.

blood pyruvate in, 315.

disease in foxes due to fish feeding, 571.

determination, 8.

determination, simple method, 479.

effect on growth of *Agrostis tenuis* and *Brassica alba*, 194.

effect on growth of rice, 195.

excretion, clinical studies, 315.

in foods and biological materials, determination, improved procedure for, 762.

in ophthalmology, 147.

in urine as determined chemically and biologically, 763.

in wheat, determination, modified thiochrome method, 8.

inactivation by raw fish, 702.

intake, low, possible adaptation to, 456.

intermediates, Mo. 145.

requirement of wax moth larvae, 401.

thiazole component, photochemistry of, 169.

Vitamin B₆—see also Pyridoxin.

chemical determination, 11.

colorimetric determination, 11.

deficiency in dog, 147.

effect on rat dermatitis, Mo. 147.

requirement of chick, 839.

Vitamin B complex—

added to diet of stabilized diabetic children, effect, 601.

and fat metabolism, 146.

deficiency, nonpellagrous eruptions due to, 147.

factors, all known, added to synthetic diet, inadequacy for mice, 749.

factors in Russet Burbank potatoes, Idaho 739.

group relation to seborrhea in man, 600.

group, round table discussion from standpoint of pediatrician, 312.

new factor requirement of mice, 456.

studies with mice, role of *p*-amino-benzoic acid in, 600.

Vitamin C—see also Ascorbic acid.

and sterility in horses, 97.

effect on workers exposed to lead dust, 318.

excretion and induced hypoprothrombinemia, 698.

in catsup, Mass. 760.

in Costa Rican fruits and vegetables, 458.

in Florida fruits and vegetables, Fla. 880.

in food crops, regional and varietal differences, Me. 303.

in fresh and canned fruit and vegetable juices, comparative costs, 457.

in milk, effect of cocoa on, Mass. 842.

in milk, effect of processing, [N.Y.] Cornell 104.

in peppers and significance as protective foods, 458.

in potatoes, 459, Mass. 605.

Vitamin C—Continued.

in potatoes, storage and cooking losses, Wyo. 880.

in sauerkraut and changes during storage, 459.

in soursop, P.R. 617.

in urine, determination, 481.

in Washington fruits and vegetables, Wash. 447.

in wild fruit products, 605.

intermittent consumption, effect of development of scurvy, 895.

nutrition in school children, 316, Me. 316.

potentiometric determination, 763.

round table discussion from standpoint of pediatrician, 312.

use of bacteria in chemical determination of, 623.

Vitamin D—

A. O. A. C. chick method of assay for, 16.

and Ertron, effect on serum calcium, 310.

assay procedure in chicks, modifications in, 839.

effect on incisor teeth of rachitic rats, 460.

massive doses, effect on vitamin K-deficient chicks, 560.

of shark-liver oil for poultry, Fla. 833.

preparations, economical purchase of, 460.

requirement of dairy cows, S. Dak. 563.

requirements of turkey poults, 562, Wash. 404.

requirements of turkeys, Pa. 554.

round table discussion from standpoint of pediatrician, 312.

spectroscopic method for estimation, 15.

stability in cod-liver oil mixed with feed, effect of manganese sulfate, 655.

supplements for poultry, Idaho 697.

uniform content in eggs, 'production, Iowa 256.

utilization by Jersey v. Holstein cattle, S. Dak. 563.

Vitamin E—

and A, interaction, 891.

and muscle degeneration in hamster, 698.

deficiency in guinea pig diet, causing death of embryo, 896.

distribution in cereal milling products, 154.

rations high in, for livestock and poultry, Iowa 257.

Vitamin G, see Riboflavin.

Vitamin H isolation from liver, 621.

Vitamin K—

and prevention of hemorrhagic disease in newborn infants, 155.

antepartum use for prevention of prothrombin deficiency in newborn, 156.

clinical studies in newborn infants, 155.

deficient diets, 155.

monograph, 461.

requirement of newborn infant, 607.

Vitamin K—Continued.

round table discussion from standpoint of pediatrician, 312.
storage and prothrombin levels in chicks, 561.
studies, 461.

Vitamin K₁—

colorimetric test for, 481.
determination, method, 626.

Vitamin P and capillary fragility, 156.

Vitamin, antihemorrhagic, *see* Vitamin K.Vitamin, antineuritic, *see* Vitamin B₁.Vitamin, antirachitic, *see* Vitamin D.

Vitamin(s)—

as fertilizers, Tex. 225.

deficiencies in sugar beet molasses, Utah 259.

deficiencies of *Ceratostomella*, 350.

deficiencies, oral manifestations of, 890.

deficiency diseases in subclinical stages, prevalence, 743.

essential in livestock and poultry nutrition, 834.

in dermatology, 600.

in plants, effect of cultural treatment, Mo. 145.

properties, functions in body, and sources, Okla. 749.

requirements of older people, Mass. 880.

requirements of rats, effect of exercise, Pa. 589.

supplements, effect on growth of infants and incidence of rickets during first years, 607.

tabulation and importance, Mo. 748.

Volutella, large-spored species causing stem and stolon canker of *Pachysandra*, N.J. 818.

Wall construction, concrete masonry, good practice in, 577.

Walnut(s)—

blight control, 242, 388.

decline and death in Oregon, causes, 242.
growth, Iowa 220.

hybrid, infertility in, 653.

"mal de la tinta" in Argentina, 242.

Persian, bacterial blight, U.S.D.A. 805.
trunk canker, 242.

varieties, N.Mex. 371.

War, effect on farm family, 609.

Washington Station notes, 468.

Washington Station report, 465.

Wasp parasite of coconut caterpillar, 403.

Water—

and soil conservation, Fla. 768.

bound, in colloidal systems, nature of, 474.

conservation and flood control project, 278.

conservation folders for farmers and ranchers, U.S.D.A. 639.

conservation with stubble mulch, 122.

control investigations, Fla. 769.

culture, *see* Plant(s), culture.

disposal planning technics, 860.

drinking, and dental caries, 890.

Water—Continued.

drinking, warming for livestock, electric heat for, Ind. 725.

flow and distribution in soil, Iowa, 183.

fluorine in, relation to well depth, Ariz. 760.

fresh, *Clostridium kluyverii* isolated from, 349.

ground, in upper Santa Cruz Valley, Ariz. 859.

heavy, purified by distillation in high-vacuum line, pycnometer for, 474.

hyacinth, toxic effect of chemicals on, 354.

irrigation, *see* Irrigation water.

mineral content, reduction with organic zeolites, 725.

of Ohio, surface and underground, 574.

pasture studies, Fla. 792.

polluted, sterilization by ultraviolet rays, N.J. 428.

red, from wells, cause and correction N.J. 428.

resources of Ohio, conservation of, 574.

rights in West, selected problems in law of, U.S.D.A. 292.

studies, aid in planning for larger acreages of war-needed crops, Colo. 631.

supplies, effect of ozonation on bacterial flora, Iowa 263.

supply, forecasting, Ariz. 859.

supply of United States, 120, 725.

surfaces, measurement of evaporation from, U.S.D.A. 310.

unfreezable, relation to cold-hardiness of insects, 821.

vaporous, quantity in atmosphere, 630.
warming for poultry, 278.

wheels, overshot and current, Mont. 431.

Waterfowl—

breeding areas, distribution and ecology of plants in, Iowa 191.

food plants, value, propagation, and management, 86.

in British Columbia, 391.

Watermelon(s)

carotenoid and provitamin A content, 312.

chemically induced parthenocarpy in, Mich. 223.

disease-resistant strains, breeding and selection, Iowa 228.

diseases, Fla. 806.

Fusarium wilt resistance, Tenn. 378.

on sand, soil acidity for, 223.

Pythium spp. on, Mo. 67.

rind toughness in, 60.

seed, globulin of, protein nutritional studies, Conn.[New Haven] 760.

variety tests, Del. 220, Iowa 220, Mo. 57.

wilt resistance in F₁ hybrids, 79.

wilt-resistant varieties, Wis. 528.

wilt-resistant variety, developing, 67.

Watershed(s)—

agricultural, subsurface water in hydrologic research on, 631.

Watershed(s)—Continued.

- and hydrologic studies on central Great Plains, 120.
- experimental, hydrologic data, U.S.D.A. 632.
- improvement programs, hydrologic evaluation, 429.
- Pecos, of New Mexico and Texas, infiltration studies, 187.

Wax moth larvae, vitamin requirement, 401.

Waxy myrtle, wood-decaying fungus of, 390.

Weather—*See also* Meteorological observations and Meteorology.

- and crop yields, U.S.D.A. 20.
- and its distribution, relation to corn yields, U.S.D.A. 340.
- factors, methods of computing regression of yield, Iowa 766.
- forecast project, long-range, 22.
- forecasting, 631.
- forecasting, daily, for Susquehanna River basin, 631.
- forecasts, comparison of methods, 181.
- forecasts, verifying, formula, 340.
- in 1941 and fruit diseases, 631.

Webworms, sod, ecology and control, Iowa 248.

Weed(s)—

- and shrubs, effect on weight gains of cattle grazing pastures, Colo. 258.
- control, N.Dak. 667.
- control by plant diseases, U.S.D.A. 680.
- control, dichloroethyl ether test for, Ky. 792.
- control implements, Ind. 725.
- control in growing corn, Iowa 863.
- control, selective sprays for, Oreg. 798.
- effect of burning off on yield of succeeding crops, Fla. 792.
- eradication in tame pastures, Fla. 792.
- germination and seedling growth form, 52.
- in grain, control by chemical sprays, Wis. 505.
- in Kansas, descriptions and control, 798.
- in lespedeza, control, Kans. 217.
- noxious, from Latin America, in United States, 348.
- of California and control, 57.
- problem in Utah, Utah 219.
- seeds, viability and germination, 512, Iowa 55.
- suspects of potato yellow dwarf virus, 75.
- trees, killing, ammonium sulfamate for, Mass. 800.

Weevil(s)—

- clay-colored, in British Columbia, 90.
- leaf-eating, on cultivated fruit trees in Great Britain, 400.

Weil's disease, distribution and diagnosis in man, dogs, and rodents, 112.

Wells and pumping machinery, Ariz. 859.

Wheat—

- activity and quality (Q_{10} and μ of catalase in, 489.
- adaptation to lowland soils and production methods, Mo. 213.
- and flour technology, 16.

Wheat—Continued.

- black stem rust control by barberry eradication, progress in, Iowa 228.
- breeding, Del. 212, Idaho 659, 679, Ill. 504, Ind. 659, Iowa 212, Mo. 52, N.Dak. 55, N.Mex. 366, Pa. 504, S.Dak. 504, Wash. 367.
- breeding for smut and rust resistance, Ariz. 791.
- bunt, *see* Wheat smut, stinking.
- combining, moisture as factor in, Pa. 504.
- culture tests, Wash. 367, Wyo. 793.
- damaged and sprouted, seed treatment for N.Dak. 195.
- date of seeding test, N.Mex. 366.
- dry-land foot rot, relation to seeding date, 219.
- effect of top dressing of N carriers and manure and efficiency of P carriers on, Ind. 659.
- einkorn, hereditary susceptibility to X-ray injury, 359.
- farms, dry land, organization and efficiency, Idaho 437.
- farms in southwestern Kansas, changes on, U.S.D.A. 293.
- fertilizer tests, Del. 212, Ind. 659, Wyo. 793.
- fields, sampling for quality and production, U.S.D.A. 442.
- flour, *see* Flour.
- foot rots, varietal resistance to, 233.
- from seed of different weight and origin, analysis of yield, N.Dak. 55.
- germ oil as supplement to poultry rations, specificity, Iowa 257.
- germ oil feeding, effect on reproduction in sheep, 97.
- germ, vitamin in, 146.
- germinating, amylase development in, effect of temperature, 489.
- growth and yield, effect of diseases, Idaho, 679.
- hessian fly resistance, variety nursery for studies, Ill. 546.
- hessian fly resistant varieties, Ind. 694, U.S.D.A. 88.
- immature, freezeable water and oxygen respiration in, 492.
- improvement for Oklahoma, Okla. 219.
- improvement program, Okla. 511.
